This question of technical education is the continuing problem presented alike by the small firm and the small yet well-defined industry unable to finance a fully constituted research association with the minimum overheads essential for really competent scientific guidance and work. For such industries the Advisory Council has sought to foster association of the smaller ones with existing and industrially related research associations. Examples of this relation which promise to meet with success are the arrangements made between the Cutlery Research Council and the British Iron and Steel Research Association, and between the latter and the File Research Council.

There are other problems presented by the small firm; but it should be remembered that, as the survey carried out for the Manchester Joint Research Council has indicated, a major difficulty is the absence in so many small firms of those competent to assess the significance of scientific and technical advance for the activities of the firm. This, however, is a matter of technical and scientific education. For the present, it appears to the Advisory Council that the past five years have demonstrated the strength and vitality of the research association movement as a whole, and the firm belief of most of British industry in the value of their associations. It concludes that industry as a whole has been spurred to increase its support of research associations by the economic situation during recent years and by some falling-off in the rate of increase of government support. Many associations, however, have far to go before their resources and activities are as large as their industries require and can reasonably be expected to support; nor are there any which, in the Advisory Council's opinion, could not usefully be expanded. Moreover, it believes that some of the terms of grant fixed in 1951 may prove to have placed too heavy a load of responsibility on the industry.

Although in terms of purchasing power there has been a substantial increase in the total income of the research associations and in industrial support, the Advisory Council is clear that inflation slows down the development of activities and sometimes causes serious financial embarrassment. It is in consequence in considerable doubt as to the adequacy of the funds at present expected to be available under the five-year plan for what was contemplated. This, it is clear, applies equally to the research establishments of the Department, and it is these and related problems that should be the prime concern of the Government at the moment. There is little evidence of misdirected effort but much of the need for clear thinking and careful assessment of the place of the Department in the nation's research organization, and it is to such problems that the Bill now before Parliament should primarily direct attention.

ORIGIN OF THE VERTEBRATES

The Origin of Vertebrates

By Prof. N. J. Berrill. Pp. viii+257. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 25*s*. net.

For a long time zoologists have accepted for embryological reasons the general proposition that vertebrates are more closely related to echinoderms than to arthropods or annelids, which they resemble superficially in segmentation. This belief has usually been combined with acceptance of the theory that vertebrate descent has involved neoteny, eliminating a sessile adult feeding phase. Willey and Garstang combined these two views in the supposition that the chordate, swimming by muscles, evolved from a ciliated echinoderm type of larva. Prof. Berrill is prepared to accept both the first two theses, but not to put them together as Willey and Garstang did. He believes that the ancestor of the chordates is to be found in the ascidian tadpole and that this was evolved not from a ciliated larva but as a special adaptive phase, concerned with the selection of a suitable location for the sessile adult.

To prove this thesis he draws on his great knowledge of tunicates, their ecology and their embryology. He points out that the tadpole's life is very short, sometimes as little as one hour. The animal consists almost wholly of a locomotor tail and receptor organs with which to guide it. Moreover, the tadpole is best developed in those species in which the adult requires a clean rock surface or some other relatively specialized surface upon which to develop. Such sites are usually at a premium—vertical or overhung surfaces, often swept bare by currents. They therefore have to be sought out by the larva. In groups such as the Molgulidae, where the adults live 'free' on a sandy bottom, the tadpole stage is absent.

His thesis that the tadpole is a new tunicate development is supported by a beautifully concise account of this exceptionally simple creature with its notochord of forty cells, with eighteen muscle cells on each side. He draws also upon investigations by Conklin and Dalcq into the localization of organ-forming substances in the egg and makes a bold suggestion as to how the whole tail structure could result from a simple mutation. If one part of the egg became changed so that a few of the cells of the gastrula swelled by formation of vacuoles to make a notochord, then, he suggests, the cells on either side would acquire myofibrils because of stretching and the nervous system would be pulled out into a tube. The chordal tissue would thus influence adjacent tissues, setting the pace of growth as he puts it, though he does not pursue the thought to the evocative powers of the vertebrate chordamesoderm. His point is that a crude form of tadpole could be produced by relatively simple changes of morphogenesis, though, as he observes, it would need receptor organs to guide its swimming.

Whether we follow Prof. Berrill in his hypothesis or not, it reminds us of the fascinating possibilities that these larvæ present for study. For example, the myofibrils run continuously through the cells all along the tail. All the control is from the front end and the 'neural tube' contains no nervous tissue. It has to be explained, however, how it comes to do so in the neotenous Appendicularia, in which development is otherwise very like that of other tunicates. Ingenious though the thesis is, it does not demonstrate conclusively that the simple ascidian tadpole represents the earliest type of chordate. It is difficult to exclude the possibility that its simplicity is due to the specialization for habitat-seeking to which he directs attention. Above all, it does not provide us with an answer to the question: What were the larvæ of our ancestors like before they were tadpoles? The enteropneust tornaria is so like an echinoderm larva that it is difficult to believe it can be dismissed as "an innovation far from primitive" as Berrill suggests. Similarly he dismisses hollow nerve cords and enterocœles as unimportant indicators of affinity, because they are due to a "simple process of folding". He several times introduces this concept that foldings of epithelial layers are the simplest form of morphogenetic process—an interesting topological and embryological question. We cannot, however, afford to discard clues in the similarities of developmental processes, at least until the underlying morphogenetic forces are understood. It is scarcely sufficient to say of an organ, as Berrill does of the nerve cord of *Balanoglossus*, that it is "inevitably situated where it is found".

He is equally provocative about the later stages of vertebrate evolution, interpreting the development of *Amphioxus* as derived from that of ascidians by a slowing of the rate of differentiation of all the tissues by a "weakening of the ascidian crescental agents", which might have come about by a relatively simple mutation.

These are only some of the ways in which the author has succeeded in showing the stimulating value of studies of the morphology and embryology even of such creatures as sea squirts. He provides some very interesting comments also on the adult structure of tunicates. There is a good account of the subneural apparatus and of the work of Huus and Carlisle on its possible receptor functions, with all that this implies for the origin of the vertebrate pituitary gland. Berrill adds the interesting suggestion that the dorsal cord, a strand of cells between the subneural gland and the gonad, controls release of the genital products by "neuroid or hormonal transmissions along its plasmal surface". Almost as an aside he introduces the conception of the tunicate epicardium as the ancestor of the coelom. All these and many other questions are discussed lightly, concisely and yet with full scholarly appreciation of their significance, making a book that every zoologist can enjoy.

J. Z. YOUNG

WILD-LIFE REFUGES IN THE UNITED STATES

Seeing America's Wildlife in our National Refuges

By Devereux Butcher. (Prepared under the Auspices of Defenders of Furbearers.) Pp. ix+338. (New York: The Devin-Adair Company, 1955.) 5 dollars.

WILD-LIFE refuges in the United States are so many, so far-flung and so astonishingly rich in vertebrates that to become familiar with the majority is an unattainable ambition for all but a very few, even of Americans. Most European naturalists have only the vaguest idea of them. One should therefore be grateful to Mr. Devereux Butcher for this highly informative book, with its three hundred and fifty excellent half-tone illustrations, which show a generous sample of the mammals and birds of the refuges, and a fair but smaller sample of the refuges themselves. Forty-one of them are briefly described, together with a number of national parks and other public and private refuges. Nevertheless, the author is compelled to dismiss more than a hundred other refuges of the Federal Fish and Wildlife Service alone, in a final ten-page summary, although several of these are each larger than all the nature reserves in Britain put together. Many hundreds of interesting State refuges cannot even be mentioned by name.

Mr. Butcher has made his selection wisely from a wide variety of habitats and regions, although coastal, desert and mountain refuges naturally come off best, and the representation of New England and the Middle West and Prairie states is disappointingly thin. He has packed his descriptions with accurate and up-to-date facts, with a minimum of padding but with a vivid and colourful presentation of what each has to show and of the achievement which it represents. The propaganda for the defence and expansion of the system and against rival interests, particularly shooting men, rings somewhat stridently to a British ear; but apart from differences in national character and tastes, it must be borne in mind that the problems created by some fifteen million 'hunters', or shooting men, have no sort of parallel in Great Britain, while threats to alienate national parks and refuges for economic or defence purposes have recently grown to very serious proportions in the United States just as much as in Britain. Nevertheless, the reader should not forget that the American restrictions on shooting wild-life, which receive bare mention in this book, are far more drastic and more strictly enforced than anything ever contemplated in Britain, and that not all who are in a position to judge would agree with, for example, the author's condemnation of the Department of Interior for permitting the New York State Throughway to be driven across the marshes of Montezuma Refuge, in view of the improved control of water-levels which it facilitated.

American wild-life is often astonishingly tolerant of human beings, who will no doubt be tempted by this most attractive book and by growing prosperity and leisure to flock to the refuges in alarming numbers. The author appreciates the danger, at any rate for the California condor, which can be prevented from feeding its only chick all day by one man showing himself within five hundred yards of the nest for a few minutes only.

Characteristically, but in contrast to British practice, the vegetation and invertebrate fauna are treated as little more than background for the main drama of the vertebrate actors. There is a certain amount of history but relatively little ecology, and little attention to the natural as against the human dangers to the successful management of refuges. It seems too much to hope that this fairly expensive work can be widely bought by private individuals in non-dollar countries but it should not be missing from any serious library concerned with Nature and its conservation.

E. M. NICHOLSON

CATALYTIC HYDROGENATION

Catalysis

Vol. 3: Hydrogenation and Dehydrogenation. Edited by Paul H. Emmett. Pp. vii+504. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1955.) 100s. net.

WITH the appearance of the third volume this comprehensive work on catalysis begins to take a new form, in that a specific type of catalytic reaction is considered in place of catalysis in general. The present collection of monographs deals with various aspects of catalytic hydrogenation. Much can be learned with regard to the mechanism of the catalytic activation of hydrogen itself from reactions such as the ortho-parahydrogen conversion and hydrogen–deuterium exchange, which are treated in an initial chapter by B. M. W. Trapnell. Catalytic hydrogenation, however, involves also the simultaneous activation of a second component, namely, the substrate to be hydrogenated; and the mechanism of this two-component process, in the typical case of the hydrogenation of ethylene, is discussed fundamentally and very clearly in the subsequent monograph by D. D. Eley. The next three sections, on the catalytic hydrogenation of olefinic hydrocarbons in general, by B. B. Corson, on the addition of hydrogen to acetylenic linkages, by G. C. Bond, and on the hydrogenation of nitro compounds, by H. A. Smith and W. C. Benoit, have largely a practical character and deal with aspects such as selective hydrogenation and the degree of specificity which can be exerted by variations in the hydrogenating metal and in the working conditions.

In connexion with a review of the present state of industrial reactions involving hydrogenation, a welcome emphasis is laid on the synthesis of ammonia. The general progress of the synthesis, including a discussion of the inherent requisites for good ammonia catalysts, is dealt with by W. G. Frankenburg on the basis of the necessary activation of the nitrogen, by chemisorptive linking of suitable bond-strength to the catalyst, in addition to the activation of the hydrogen. This is followed by a monograph by a group of chemists from the Dutch Staatsmijnen on research on the ammonia synthesis since 1940, the outstanding feature in this section being a clear exposition of the mechanism of promotion. The synthesis of methanol is discussed by G. Natta with special reference, first, to the necessary specificity of action which is required in the catalysts employed in order to avoid the formation of polymeric products, and, secondly, to the merits of particular catalysts. R. Feuge contributes a practical account of modern methods of working in the industrial hydrogenation of glyceride oils. In this, the discussion of forms of nickel catalysts alternative to kieselguhr-supported nickel prepared by the reduction of basic nickel carbonate is particularly valuable. Finally, the technical dehydrogenation of hydrocarbons in the petroleum industry is described, perhaps too briefly, by K. K. Kearby.

Considered as a whole, this volume represents a fair balance between the academic and the industrial aspects of hydrogenation. Its component articles are of a consistently high quality. It certainly stands out from the earlier volumes of the work, in particular from the point of view that chapters containing tables of largely undiscussed references to patent and other literature are absent; and Dr. Emmett is to be congratulated on assembling, within the compass of some five hundred pages, such an authoritative and internationally contributed description of catalytic hydrogenation.

E. B. Maxted

AUTOMATIC REGULATION

Servomechanism Analysis

(McGraw-Hill Electrical and Electronic Engineering Series.) By George J. Thaler and Robert G. Brown. Pp. xii+414. (New York and London: McGraw-Hill Book Company, Inc., 1953.) 60s. net.

At a time when so much is written and talked about the automation of manufacturing processes, the automatic control of aircraft, guided missiles and the like, a book is welcome which sets out to give the mathematical background for the analysis and design of servomechanisms. The present volume under review is written in a fluent and clear style and contains a great number of worked examples and of problems enabling the student to ascertain whether he has grasped the contents of the chapters he has read and to gain some experience in handling actual problems of control. A very welcome feature is a brief and sufficiently clear introduction to the theory of Laplace transformations which are used throughout the book.

As problems of electric circuits can usually be solved with not too great difficulty either directly or with the aid of analogue computers, electrical analogues are set up of mechanical, thermal, hydraulic and pneumatic systems. The book then deals with the transient analysis of servomechanisms, that is, the derivation, solution and discussion of their differential equations for determining the main criteria of performance, the speed of response, the steady-state error, the maximum overshoot and the resonant frequency for the case when changes in input or output occur. Proportional as well as derivative and integral control are dealt with.

The next chapter deals with transfer functions and their graphical representation, the transfer function being defined as the complex ratio of the output of the device to its input (p. 112). The authors seem to be not quite consistent in that a few pages later (p. 126) they call this ratio the frequency response function, while the direct transfer function is defined as the ratio between output and error, this latter being the difference between input and output. The reason for this apparent inconsistency is given on p. 140 and following.

Simplifications are made for the mathematical analysis by replacing complicated schematic drawings by equivalent block diagrams and by introducing a shorthand notation for the transfer function, representing it as the product of a constant factor K and a complex factor G. The symbols K and G are replaced by A and F respectively if a control element is used in the feedback path. Frequency response curves and curves of direct and inverse transfer functions are given in rectangular and polar co-ordinates, respectively. Then the performance of servomechanisms is analysed from equations and plots, stability criteria are discussed at some length, a classification of the systems is given and figures of merit are defined. Only very brief chapters deal with the introduction to design and with gain adjustment. A trial-and-error method and direct methods for the gain adjustment are given.

Where gain setting alone is not sufficient for obtaining the desired values of resonant frequency and steady-state error, some kind of compensation must be applied either in the main circuit or in a parallel circuit. Series and parallel compensation are therefore dealt with at some length in the next two chapters. Then it is shown how, by the use of logarithmic co-ordinates, analysis and design may be simplified in many cases. A brief chapter deals with relay servomechanisms as these find wider and wider application. Here electromechanical relays are used for applying full power to the output when the error is excessive and to maintain it until the error is sufficiently reduced. The final chapter, dealing with the 'root-locus method', might be of particular interest, as this method claims to combine to some extent the advantages of the transient and the transfer function analysis. But, due to limitations of space, only the elements are given and the chapter is somewhat sketchy.

The authors do not claim originality for the material contained in this book, but have found in their teaching practice that the arrangement and detail of presentation are well suited for the student. This is also my impression. While the various systems of servomechanisms are treated in the text in a rather abstract manner, the student will find in the appendixes, apart from some useful tables, more detailed physical and technological descriptions of the components used, like error detectors, *controllers*, servomotors and compensating devices. A subject-matter index and a bibliography of 206 items complete this well-produced book. As is not uncommon in American publications, only very few references are made to British and Continental sources.

R. Neumann

Index of Mathematical Tables from All Branches of Sciences

Prepared by Dr. Karl Schütte. (Index Mathematischer Tafelwerke und Tabellen aus allen Gebieten der Naturwissenschaften.) Pp. 143. (München: R. Oldenbourg, 1955.) 14.50 D. marks.

BEFORE reviewing the contents of this book, it is of some interest to recall a few facts concerned with the relatively short history of such works. It was in 1873 that British mathematicians first conceived the idea of publishing a survey of available tables, and their efforts were responsible for the appearance in 1875 of the "Encyclopaedia of Mathematics" which listed some 750 tables in all. In the meantime, with the growth of technological research, involving as it does much detailed computation, the number of tables has steadily increased, and the comparatively recent "Index of Mathematical Tables", by Fletcher, Miller and Rosenhead, of 1944, gives a selection of more than two thousand.

The author of the book under review explains that his own work was begun before the Second World War and was temporarily halted for the duration thereof; on examining Fletcher's "Index" in 1946, he found that nearly four-fifths of his entries were not in fact shown in that work; he thus decided to complete it, there being in any event no German counterpart of recent date. He claims some twelve hundred entries, of use to "calculators" of various kinds, belonging to all the branches of applied science. He also claims, justifiably I feel, that its comprehensiveness and clear order enhance its value considerably, pointing out at the same time that out-of-date tables and all three-figure ones have been omitted.

The book is divided into sixteen chapters, with sub-sections where appropriate. The first four deal with general calculating (including harmonic analysis), logarithms, natural circular functions, and logarithms of these. Of the remaining twelve, those worthy of special mention deal with the theory of numbers (including primes), gamma functions, elliptic functions, Bessel functions and the many other varieties with which mathematicians and physicists are familiar. It would be unfair to omit mention of those referring to chemistry, astronomy, meteorology, geophysics and navigation. A very full (and almost formidable) list of authors whose publications are listed is provided, together with a similar list of institutes.

J. H. PEARCE

General Physics

By Prof. Oswald Blackwood and Prof. William Kelly. Second edition. Pp. x+704. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 54*s.* net.

Introductory Applied Physics

By Norman C. Harris and Edwin M. Hemmerling. Pp. viii+729. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 50*s.* 6*d.*

EACH of these beautifully produced books from the United States is written for a specific purpose which is somewhat different from that of the ordinary text-book. Profs. O. Blackwood and W. Kelly give an introductory course based on no more initial background than awareness of the obvious impacts of physics upon everyday life. Indeed, their hints on the solution of simple equations, arithmetical extraction of square roots, and the pronunciation of unfamiliar words, show that they assume a fairly low threshold for some students. They are also quite determined that this shall be no excuse for being content with a superficial knowledge of the principles of physics. A thorough understanding of the simpler processes of physics, and a sensible appreciation of its applications, are brought within the grasp of any careful reader, and this is no mean achievement. As in most books of this kind from American universities, the treatment of elementary mechanics is particularly good. The price puts it beyond the reach of British schoolboys (and, *a fortiori*, of their teachers), and it is in any event difficult to see where it would fit into any ordinary scheme of instruction in Britain; but it can be recommended to the librarian with a surplus to expend.

N. C. Harris and E. M. Hemmerling, writing for students in junior technical colleges, also assume only an elementary knowledge of mathematics; but having a much fuller background of scientific knowledge to exploit, they work at a more exacting level. Here the emphasis is on industrial applications. Heat engines, refrigeration and air-conditioning are pursued in great detail, and there is a very thorough treatment of alternating current and electronics. The standard is not advanced in the academic sense, and the whole is within the capacity of the young technical student, who should find it an inspiring book. This also is priced at library level.

G. R. NOAKES

Chemistry for Our Times

By Elbert C. Weaver and Laurence S. Foster. Second edition. Pp. vi+666+8 plates. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 30*s.*

ALTHOUGH written as a text for American high schools and university freshmen, the theme of the book is chemistry as it affects the citizen. In the preface to the first edition (1947) the authors maintained that the atomic age called for a new approach to the study of chemistry. In framing this, fundamental principles and industrial applications were treated in due proportion and always with the humanistic appeal. Thus, while the factual chemistry was not much more than that required for British O-level examinations, it was accompanied by many literary quotations, and an abundance of information on such topics as the cyclotron, cosmetics, dyes, nuclear energy, and accounts of economic applications of chemistry. Numerous striking and even sensational stories, and many good illustrations in half-tone, heightened the effect. The idea seemed to be to attract students to the study of chemistry by extolling its spectacular advances. The theoretical explanations, clear but nowhere deep, were clever in their simplicity.

In this, the second edition, the authors have deleted the more sensational stories and pictures, have shortened the literary quotations, recast the appendixes, removed the coloured frontispiece but inserted eight coloured plates, and added items to make their work more of the style of the conventional text-book. These changes in their aggregate reduce the number of pages from 737 to 666. Yet this remains a remarkable book. Many plates have been replaced by others depicting more recent procedures. Although expensive, and scarcely suited as a class-book for any British examination, it should appeal to the student of humanities desirous of having chemical achievement introduced and interpreted to him: it would also make a welcome addition to a school library.

G. FOWLES

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

ANNUAL REPORT FOR 1954–55

THE annual report of the Department of Scientific and Industrial Research for the year 1954–55* includes the report of the Committee of the Privy Council for the year ended September 30, 1955, over Lord Salisbury's signature, and the fortieth report of the Advisory Council, signed by Sir Hugh Beaver, which gives the usual summary of work carried out by the various research stations and boards and research associations. Besides the summary of the Department's expenditure for the year ended March 31, 1955, there are appended lists of assessors to the Advisory Council, of the various committees of the Advisory Council, of research boards of the Department and their membership, of grants for special researches in progress or authorized during the year, of students awarded maintenance allowances for postgraduate training in research and a 49-page list of publications issued during the year. The Advisory Council can fairly claim at the outset that the Summary of Work and Appendixes afford a valuable means of obtaining easily detailed information regarding the work of the Department in widely varying fields; but the question as to whether the present organization is adequate to deal efficiently with matters of public relations remains to be determined. The persistence and the character of Parliamentary questions suggest that the problem is not yet solved, and it is improbable that an annual report of this type can contribute greatly to a solution.

The gross expenditure of £6,685,400 compares with £5,865,279 in the previous year and is reduced to £5,898,016 net by various receipts (£370,536 being from the National Physical Laboratory) for work done for government departments or for industry, the net increase on 1953–54 being £643,674; the estimates for 1955–56 provide for a further increase of £630,154, and those of 1956–57 for a net increase of £1,023,930. On October 1, 1955, the Department employed 4,379 staff of all grades (including 190 part-time) compared with 4,220 (164 part-time) in the previous year. Annual grants to research associations totalled £1,335,125 (compared with £1,254,088 in 1953–54), grants for special researches amounting to £315,425 (£412,431 in 1953–54). Grants to students amounted to £323,022, an increase of £27,603, the number of students in training in 1954 being 1,052, and in 1955, 1,022, compared with 1,009 in 1953; and of these, 381 in 1954 and 379 in 1955 were new. Of eight senior research awards in 1954 and in 1955, two in 1954 and five in 1955 were new, and 26 new grants for special researches in 1954 and 15 in 1955 brought the total of such grants to 64 and 53, respectively, compared with 58 in 1953 and 70 in 1952. Of the grants for special researches, 37 in 1954 and 33 in 1955 were in physics; for chemistry the figures were 9 and 9; for biology and also for engineering, 6 and 4; and for mathematics and astronomy, 3 and 1. In 1954 chemistry claimed 428 and in 1955, 399 of the students receiving grants; in physics the corresponding figures were 301 and 262; in engineering, 104 and 91; in biology, 97 and 107; in mathematics and astronomy, 60 and 86; in geology and mineralogy, 36 and 42; and in metallurgy, 26 and 23.

Expenditure of £926,971 gross or £556,435 net on the National Physical Laboratory was slightly more than in 1953–54 (£513,049 net), and this is true of expenditure on all branches of the Department's activities, except fire research, which decreased by £2,922 to £22,433; the increase on 1953–54 was, in general, about 10 per cent, apart from the contributions to European Nuclear Research, which increased from £42,483 to £359,787. Expenditure on mechanical engineering research only increased, however, by £1,154 to £315,561. Net expenditure under the other major headings in 1954–55 was as follows, the increase over 1953–54 being given in brackets: building research, £453,049 (£41,455); food investigation, £373,208 (£81,090); road research, £343,516 (£37,984); fuel research, £270,419 (£23,535); geological survey and museum, £223,410 (£12,670); chemical research laboratory, £136,350 (£11,997); forest products research, £116,487 (£15,235); radio research, £107,298 (£12,901); hydraulics research, £76,169 (£14,607); water pollution research, £74,321 (£11,648); pest infestation, £68,145 (£9,388); headquarters administration, etc., £247,915 (£27,536).

The contribution to the European Organization for Nuclear Research was increased to £520,000 in the 1955–56 estimates and further to £930,000 in those for 1956–57, while of the grants for special researches some £250,000 of the total £315,425 is for support of nuclear physics research in universities. This total was increased to £422,200 in the 1955–56 estimates and to £497,000 in those for 1956–57. These grants were provided for the installation and operation of the large particle-accelerating machines for research in nuclear physics in the Universities of Birmingham, Cambridge, Glasgow, Liverpool and Oxford, and the Advisory Council has endorsed the recommendation of the Nuclear Physics Committee for supplementary grants of £7,720 to the University of Glasgow and £14,200 to the University of Liverpool. A grant of up to £82,000 to the University of Manchester for the installation of a 6-MeV. Van de Graaff generator for research on nuclear structure has also been recommended by the Advisory Council.

Although the European Organization for Nuclear Research receives the major part of the Department's contribution to international co-operation, developments during the past year in desalting brackish waters have provided an interesting example of the difficulties as well as the possibilities of international co-operative research. A working party concerned with this subject, after considering a report on existing and potential processes for desalting, recommended that meetings should be called by the Netherlands to discuss electrodialysis with ion-exchange membranes, by the United Kingdom to discuss the prevention of scale formation in distillation equipment, and by France (in Algeria) to discuss solar distillation and certain aspects of ion exchange. Out of these meetings during the current year has come an agreement signed by Algeria (for France), Australia, South Africa, the Netherlands and the United Kingdom, under which, in return for a share of the development costs, the United Kingdom will have a voice in the development of the process of electrodialysis with ion-exchange membranes in the Netherlands and rights under Netherlands patents. Under a less formal agreement on scale-prevention work, the Department has contributed funds to permit expansion of the existing Admiralty research group, and the Netherlands have provided an additional research worker for the team.

Government Establishments

The Advisory Council's report refers again to the urgent need for a new Fuel Research Station and, as a prelude to planning a new station, has reviewed the policy which should govern the future work of the Fuel Research Organization. As a result, the Council has recommended that the Fuel Research Station should maintain its position as a national centre for the study of fuel problems free from political considerations and pressure of sectional interests; that the Station should aim at becoming the central organization in Britain for long-term basic research on fuel; and that it should not usually undertake applied research beyond the stage at which this can properly be transferred to other organizations engaged on fuel research. On this basis, it recommends construction of a new Fuel Research Station as a matter of first priority, and it is understood that the Ministry of Fuel and Power is in broad agreement with this policy and that the Committee of the Privy Council for Scientific and Industrial Research has adopted these recommendations.

About one-fifth of the total effort of the Station is now applied directly or indirectly towards reducing pollution of the atmosphere by the treatment and utilization of fuels and their products. Semi-automatic equipment for the elimination of smoke has been devised and tested on the Lancashire boiler at the Research Station with satisfactory results, and attention is also being given to coal-fired and oil-fired central-heating boilers with the object of increasing efficiency while decreasing emission of smoke. Work on the removal of oxides of sulphur from boiler flue gas by the use of ammonia has shown that by working the process in two or more stages the sulphur can be recovered as ammonium sulphate with an efficiency of 96 per cent and loss of only 3 per cent of ammonia, and as a result of these experiments the Central Electricity Authority is erecting at the Nottingham generating station a pilot plant to treat 2 million cubic feet of flue gas per hour. After examining the fluidized catalyst process for the Fischer–Tropsch synthesis, attention has been given to the 'liquid phase' or slurry process, in which synthesis gas is bubbled through a suspension of powdered catalyst in heavy oil or molten wax; and studies continued of the changes occurring in residual fuel oils on storage that makes them difficult or impossible to pump, with the view of devising a test that will make it possible to predict the behaviour of a freshly prepared oil. Examination of the industrial processes to which coal is submitted indicated that on carbonization of coals containing 6–10 parts of germanium per million, up to 90 per cent of the germanium remains in the coke, and that the germanium contents of the dusts collected in heating-flues of the coke-burning producer of a coal carbonization plant rose to a maximum of three per cent in the recuperator.

The research stations with the work of which the Advisory Council's report is this year particularly concerned are the Fire Research Station and the Forest Products Research Laboratory. Both were visited by the Advisory Council, which was well satisfied with what it saw. It is convinced that the Fire Research Station is a continuing success. Although administered in detail as a government research establishment, it is a joint organization controlled by the Department and the Fire Officers' Committee, each contributing one-half of the running and capital costs. Under a new agreement recently concluded between the partners, the current annual expenditure will be increased from just under £90,000 to a maximum of £125,000, and the non-industrial staff will be gradually increased from just under 80 to more than 100. Extensive new buildings and equipment are to be provided at a cost of up to £365,000, and one of the new buildings, towards which and towards the general site the Fire Service Research and Training Unit has made a grant of £70,000, will provide facilities for the study of fires in large-scale models under controlled conditions. Work during the year has included an inquiry into the effect of heat on various types of high-tensile steel used in the construction of pre-stressed concrete, and the development of a new roof test and a new test for combustible wall linings; and a committee has been established to advise on a research programme on industrial fires and explosions.

Some 35 per cent of the staff effort at the Forest Products Research Laboratory (and also at the Building Research Station) is at present devoted to advisory and related work—a proportion which the Advisory Council regards as too high, and it hopes that the industrial research organizations will in future relieve the Laboratory increasingly of this type of work, leaving it freer to conduct more fundamental investigations. In particular, the Research and Information Committee of the Furniture Development Council and the Research and Development Committee of the Timber Development Association are expected to assume increasing responsibility for applied research in this field. Work during the year has included experiments with growing English ash which indicated that the degree of lignification of the fibre walls (which affects the strength of wood) is at least partly controlled by the illumination received by the leaves. A series of tests of the moisture gradient of wood carried out over a year indicates that where, as in boats or vats, the wet face cannot be painted, the dry face should also receive no paint, or at most only a thin pervious coat. Estimates of the strength of laminated timber have been extended to the study of beams from two different species, and research is being carried out on the permeability of woods to liquids and gases, on the factors that govern the susceptibility of various zones of Corsican pine to infestation by the furniture beetle and the house longhorn beetle, and on the bending vibration and damping of wooden beams and rectangular plates.

The proposals for the organization of practical trials in collaboration with the National Federation of Building Trades Employers met with a good response from the members, and a series of trials with aerated mortars has been completed, while the Building Research Station has also made good progress in developing a process for the production of light-weight aggregate from pulverized fuel ash. In designing large rigid frames, the main problem is to find a method which is sufficiently accurate while avoiding heavy design costs. It has now been shown that the behaviour of a frame to be designed can be deduced by reference to an idealized substitute frame which has already been analysed, and a new method of design for stanchions is being developed which will lead to further economy. Particular attention is being paid to the problem of measuring the stress in the linings of deep tunnels in clay and, as a result of the work on schools which has continued for some five years in collaboration with the Ministry of Education architectural development team and the Hertfordshire County Council, a body of essentially new information has been made available to designers, in terms of which they have been able to plan for fuel economy and design economy in schools.

Commenting on the work of the Chemical Research Laboratory, the Advisory Council expresses the opinion that the present programme of the Laboratory is well chosen and that, although the Laboratory's work on semi-permeable membranes, including membranes with ion-exchange properties, is limited, it has already made important contributions and should be continued and if possible extended. During the past year the trades concerned have been steadily brought into closer contact with the preparation of the Food Investigation Organization's programme and its work and, in the Fish Division in particular, close liaison has been effected with the White Fish Authority and the Herring Industry Board. The trawler *Northern Wave* has been chartered for a joint experiment in freezing at sea on a commercial scale, and special attention is being given to research on smoke-curing with the view of developing more convenient, controllable and economical procedures and of producing cures of white fish and herrings of consistently high average palatability and keeping quality. Plans have been drawn up for an experimental unit to be attached to a new centralized abattoir, and studies of fresh and frozen beef have continued. Recent storage trials have indicated that pears could be kept for longer periods at 30–31° F. without suffering low-temperature injury, and work is also being continued on the effect of field factors on the chemical composition and storage life of apples. A coating of sulphonated polystyrene on diatomaceous earth has proved valuable in the chromatographic purification of insulin and a similar method has been developed for purifying meat myoglobin.

The Geological Survey has made continuous progress since the War with the primary six-inch survey, which is the basis of all Geological Survey work, and with the first six-inch re-survey of areas of economic importance; it has also re-published ninety-two one-inch to the mile maps in colour-printed editions and extra editions of ten other maps printed to show solid geology only, making a total of 102. But only four of the twenty-four quarter-inch geological maps of England and Wales have been re-published and nineteen of the sixty-two one-inch sheets of Scotland, with fourteen additional sheets showing drift geology. All ten of the seventeen quarter-inch geological maps of Scotland published before the War have been reprinted. The Geological Survey has also statutory obligations under the Mining Industry Act (1926) and the Water Acts of 1945 and 1946, while the Museum of Practical Geology, which again had a record number of visitors (374,353), has acted as a study centre for geological research and exhibition of collections of minerals, gem-stones, rocks and fossils. During 1954, 270 square miles in Great Britain were covered by primary six-inch survey, and 253 square miles, including 75 square miles in Northern Ireland, by revision survey. Boreholes drilled during recent years continued to provide much material calling for specialized petrological investigation, and during 1954 more than eight hundred boreholes were notified to the Geological Survey under the terms of the Mining Industry Act and more than 300,000 ft. of strata were examined, identified and described. The Survey itself is drilling four boreholes in the Ashover district north-east of Matlock to ascertain the sequence and structure of the Millstone Grit and higher parts of the Carboniferous Limestone between the Derbyshire coalfield and the limestone country west of Matlock. The task of encouraging the search for the mineral raw materials necessary for the Atomic Energy Authority's programmes remains with the Atomic Energy Division of the Geological Survey, and besides further searches for uranium, attention is being given to a search for thorium deposits and to the development of new methods of geophysical and geochemical prospecting, particularly to fundamental research as to the most profitable lines for conducting geological exploration.

The work of the National Physical Laboratory and the Chemical Research Laboratory for the period have been reviewed in these columns fairly recently, so no more need be added here than that the Digital Electronic Universal Computing Engine (Deuce) was installed early in 1955, and the construction of the final Automatic Computing Engine started. The High Temperature Fatigue Laboratory has now been transferred to the Mechanical Engineering Research Laboratory, the staff of which increased by 13 per cent during the year. Two further symposia, dealing with precision electrical measurements (November 1954) and boundary layer effects in aerodynamics (March 1955), have been held in the National Physical Laboratory.

The first stage of the main hall of the Hydraulics Research Station was completed in January 1955 and arrangements have been made with river boards and coast protection authorities to collect data on beach movements and all matters bearing on coastal protection; analysis of these observations will provide valuable information on long-term trends of erosion or accretion. The investigation into the behaviour of storm surges in the Thames Estuary has been extended to examine the effect which a barrage would have in reducing storm surges of various magnitudes, and the large model of the River Thames is being used for investigating the general pattern of estuarine circulation and its relation to the tendency for serious silting to occur in the so-called "Mud Reaches" immediately downstream of the Royal Docks. A model of the tidal reaches of the River Trent is being constructed. A second model has been built in connexion with the Severn River Board's scheme for the relief of flooding on the River Severn; this includes 24 miles of the river downstream from Shrewsbury to Buildwas, and it is being used for ensuring that the reduction of floods in the neighbourhood of Shrewsbury will not lead to more serious flooding elsewhere along the river. Basic experiments in the 54-ft. wave tank have indicated that a screen of spaced piles offshore from a sand beach did not cause the beach to build up but halted or almost halted erosion, and two-dimensional wave tests have been carried out for the Kent River Board on a model of a section of the proposed Dymchurch sea wall. The proposed design of a new harbour to be constructed at Tema on the Gold Coast is being investigated in Wave Basin No. 2.

Biological research in the Pest Infestation Laboratory included field-work on residual populations of insects in farm buildings, in an old watermill and in disused dock storage sheds. Research on grain storage was largely confined to the experimental storage of damp grain in airtight silos; that on insecticides included a new method for the chemical assay of pyrethrins, the control of bean weevils with insecticidal dusts, the mechanical protection of goods from infestation by sheeting, and the relative susceptibility of different insect species to pyrethrins. Long-range biochemical work was concerned with the nature and significance of insecticide residues in foodstuffs and mechanisms of insecticidal action.

In the Radio Research Organization the main emphasis continued to be on the factors which affect radio waves during transmission between the transmitting and receiving stations; but the importance of the work on semiconductors and on ferromagnetic materials is also stressed, the former being concerned with noise generation in germanium and components made from it and with measurements on transistors. In the field of navigational aids, the main interest is in low-frequency and very low-frequency position-fixing applications and, at higher frequencies, in radio direction-finding.

A main group of researches carried out by the Road Research Laboratory seeks to provide road engineers with the basic information needed for decisions as to the most satisfactory and economical types of road construction for particular conditions of soil, traffic and climate; and the Ministry of Transport and Civil Aviation's programme of new road construction will provide the necessary opportunities for full-scale experiments. A scheme has been introduced by which the results of research are embodied in agreed specifications for use on selected sites under conditions of good normal commercial practice. Evidence is accumulating that the separation of motor traffic from other road users decreases accidents, and a study has been made of eighty-six sites reported as the scene of repeated skidding accidents. The Laboratory's work on non-destructive tests for measuring the strength of concrete by an ultrasonic pulse technique has been summarized and the equipment required is now being manufactured.

The new Water Pollution Research Laboratory at Stevenage was officially opened on June 20, 1955, and investigations in progress include a detailed study of the effects of pollution on rivers and estuaries, fundamental work on processes of sewage treatment and the investigation of methods of treating industrial waste waters. Progress was made in studying the oxygen balance of the Thames Estuary and in attempts to predict the effect of polluting discharges on the content of oxygen in the estuary water. Observations on the effect of sewage effluent on the River Colne near Watford have been completed, and tests with seven popular proprietary washing powders indicated that 50 per cent of rainbow trout were killed in about seven days in a solution containing the equivalent of rather less than 6 p.p.m. sodium dioctylsulphosuccinate.

The work of the Intelligence and Information Division of the Department is mostly directed towards the improvement of industrial productivity, and altogether a programme of twenty-nine projects concerned with human factors in industry and costing more than £155,000 from Conditional Aid Funds is guided by the two joint committees of the Department and the Medical Research Council and serviced by the Division. Most of the projects are being carried out by the universities, independent research institutions or research associations; but one concerned with problems of work study, including those of introduction, such as the reasons for suspicion and resistance, the assessment of results in terms of the impact on efficiency and human relations within firms, and problems of continuing application, is being undertaken within the Division. Work has continued on the sample survey of research expenditure of private industry, and an economist was appointed to help the Food Investigation Organization and the Pest Infestation Laboratory assess the economic relevance and application of their current work. The Industrial Operations Unit has demonstrated the value of a more systematic study of industrial operations, particularly of improved methods of planning and controlling work, and a survey has been initiated of technical developments leading to automatic processes in industry and of the broad economic and social implications of these developments. During the year, following successful pilot-plant trials of a suggestion that effluents might be treated with ammoniacal liquors from gas works to produce ammoniacal sulphate and a hydrated iron oxide, the Gas Council decided to erect a full-scale plant. The iron oxide will be mixed with peat and used for sulphur recovery, and besides reducing imports of bog iron ore the new process will reduce the demand of the gas industry for sulphuric acid.

(*To be continued*)

CHROMATOGRAPHY AND PARTITION OF CELLS AND CELL FRAGMENTS

By PER-ÅKE ALBERTSSON

Institute of Biochemistry, University of Upsala

THE study of isolated cell particles has given much information about the organization of the cell. The method which is generally used for fractionation of the particles from a homogenate is differential centrifugation. In that method, differences in the sedimentation velocities of the particles are utilized for their separation, and differences in sedimentation velocities depend mainly on differences in size, density and form of the particles. Ultracentrifugation in density gradients has also been used for the same purpose. Here the difference in particle density is the determining factor. It should be possible, however, to utilize differences in other properties, too; for example, physical and chemical properties of the surface and the electrical charge of the particles.

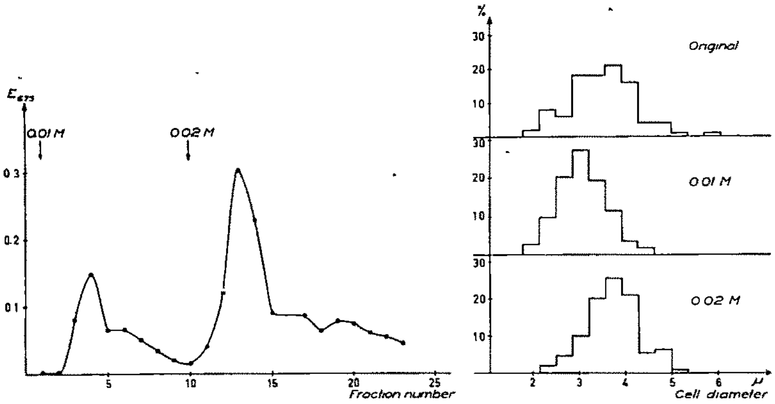

Fig. 1. Chromatography of *Chlorella pyrenoidosa* on calcium phosphate. Left: the two peaks which are obtained by elution with 0·01 *M* and 0·02 *M* phosphate buffer *p*H 7. Right: distribution polygons of cell diameters in the original suspensions and the two elution peaks. Temperature, + 4° C.

These properties, among others, determine the adsorption behaviour of the particles on an adsorbent, which means that it should be possible to apply the method of chromatography. Further, these properties determine the affinity of the particles to the two phases of a liquid–liquid system, which means that fractionation could be performed by partition. This article will describe some experiments which have been carried out in order to apply these two methods to cells and cell particles.

Chromatography. Tiselius[1] refers to the successful chromatography of proteins of high molecular weight[2], viruses[3] and cytoplasmic granula[4] and points out that the upper limit of the size of the particles to be chromatographed has not yet been reached. Recently bacteria have been chromatographed[5], and human platelets have been concentrated by an adsorption technique[6].

When an attempt is made to chromatograph cells and cell fragments many practical difficulties are encountered. Often the particles have a tendency to aggregate on the adsorbent or to be irreversibly adsorbed by it. In addition, due to their size (usually 0·1–10μ) the particles often cannot pass through the pores of the adsorbent. This latter problem, however, can be solved by one of the three following procedures.

The first and simplest one is to use an adsorbent with very large grains compared with the particles to be chromatographed. It has thus been possible to use a very coarse calcium phosphate preparation from ignited bones according to W. F. Anacker (personal communication) for the chromatography of *Chlorella pyrenoidosa* Pringsheim. A suspension of the algae from a conventional culture was allowed to pass through an ordinary column packed with this calcium phosphate. The cells were adsorbed and could then be eluted by step-wise increase in concentration of phosphate buffer *p*H 7 [2]. The amount of *Chlorella* in the different fractions was followed by the extinction at 675 mμ measured in a Beckman *DU* spectrophotometer. As is seen from Fig. 1, peaks were obtained for 0·01 and 0·02 *M*. Fractions from these were analysed in the microscope and the cell diameter was measured. As is seen from Fig. 1, larger cells have been eluted at higher phosphate concentrations. It was found, too, that the concentration of dividing cells was about ten times higher in the 0·02-*M* peak. There was no significant difference in cell diameter between fractions within a peak.

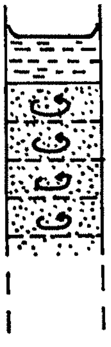

Fig. 2

This experiment suggests that chromatography can serve as a method for obtaining more uniform suspensions of micro-organisms. It has also recently been demonstrated by Maruyama and Yamagata[5].

The second method is to work batchwise by shaking the suspension with the adsorbent, allow the latter to sediment, then decant the supernatant and eventually make this procedure continuous, as is done in Craig's counter-current extraction. In this way a suspension of disintegrated *Chlorella*, obtained by vibrating a suspension in the Mickle disintegrator[7], was shaken with 'Dowex 3' at *p*H 6·5 (0·2 *M* phosphate). All particles except the starch particles were adsorbed. After these had been washed away, the cell walls could be eluted in a very pure state by changing the *p*H to 7·5.

The third alternative is to perform the separation in a column in which the adsorbent grains steadily move so that the particles to be chromatographed can penetrate the column. The ideal movement of the adsorbent should then be such that mixing of the grains occurs only within thin horizontal layers (see Fig. 2). In practice, however, a vertical mixing between the layers is difficult to avoid, so that an adsorbent grain 'diffusion' takes place which will cause broadening of zones. Despite this disadvantage, a column has been constructed according to this

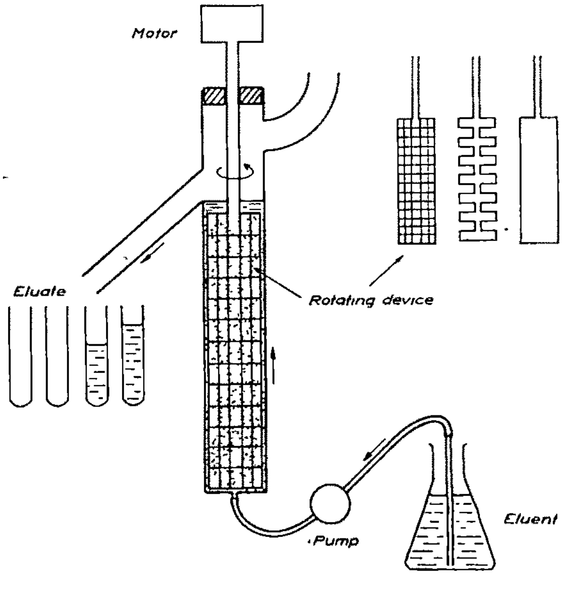

Fig. 3. Chromatography column with rotating adsorbent layers. The rotating device can have one of the indicated forms (upper right). The two to the right are made of 'Plexiglass'; the one to the left, which is the most effective, is made of a net of metal wire

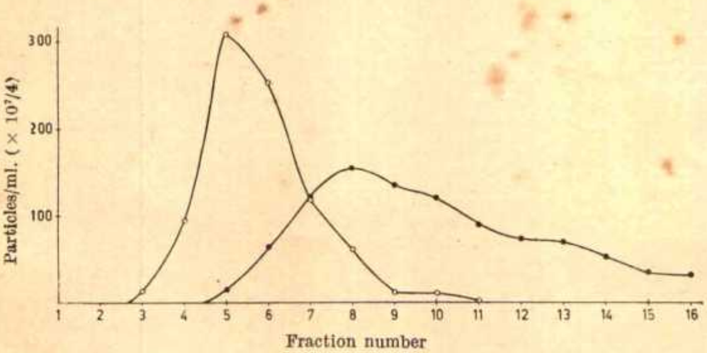

Fig. 4. Chromatography of disintegrated *Chlorella pyrenoidosa* on calcium phosphate. Elution of cell walls and starch particles with 0·2 *M* phosphate buffer, *p*H 7. Temperature, + 4° C. ○, cell walls; ●, starch grains

principle (see Fig. 3). It is made of 'Plexiglass' and provided in the centre with a rotating device which can have different shapes and is driven by a motor (4 revs. per min.). This rotation makes the adsorbent grains move around mainly horizontally. The solvent is introduced at the bottom by means of a pump (about 8 ml. per hr.). Ascending flow is preferred in order to make the packing of the adsorbent weaker and hence the resistance against the rotation smaller. The eluate is collected through a side tube into a fraction collector. A suspension of disintegrated *Chlorella pyrenoidosa* in 0·2 *M* phosphate buffer was pumped through such a column packed with a fine-grade calcium phosphate preparation, according to Ö. Levin (personal communication). In the eluate cell walls and starch particles appeared. In each fraction the number of these particles was counted in a counting chamber. The result is shown in Fig. 4, where the concentration of each particle is plotted against fraction number.

Table 1. PARTITION OF SOME CELLS AND CELL FRAGMENTS IN THE TWO-PHASE SYSTEM WATER/POTASSIUM DIHYDROGEN AND DIPOTASSIUM HYDROGEN PHOSPHATE/POLYETHYLENEGLYCOL 4000

Particles	System I*	System II†
Serratia marcescens	*B*	
Chromobacterium sp.	*B*	
Corynebacterium sp.	*B*	
Nocardia sp.	*T*	
Ophiostoma multiannulatum	*B*	*I*
Chlorella pyrenoidosa	*B*	*I*
Disintegrated *Chlorella* :		
Chloroplast fragments (microscopic)	*I*	*I*
Chloroplast fragments (submicroscopic)	*T*	*T*
Cell walls	*B*	*I*
Starch grains	*B*	*B*
Spinach chloroplast	*I*	
Starch grains and fragments of cell wall of spinach	*B*	

* I = 79·6 per cent H_2O; 10·5 per cent $KH_2PO_4 + K_2HPO_4$; 9·9 per cent polyethyleneglycol (per cent by weight).

† II = 77·3 per cent H_2O; 13·9 per cent $KH_2PO_4 + K_2HPO_4$; 8·8 per cent polyethyleneglycol.

B = Bottom phase. *T* = Top phase. *I* = Interphase

Partition. According to Brönsted[8], the higher the molecular weight of a substance subjected to partition between two liquid phases, the greater the quantity which tends to go into one of the phases. While one can still measure finite partition coefficients for proteins[9], the coefficient for a cellular particle, which has a very high 'molecular weight', will be either zero or infinite. This means that if a liquid–liquid system is shaken with a suspension of identical particles, we should find all these, according to Brönsted's theory, either in one phase or the other. In practice, however, adsorption occurs in some cases on the interphase between the two phases. This phenomenon can be explained if it is looked upon from the point of view of surface tension. Depending upon the values of the interfacial tensions between a particle and the two phases and the interfacial tension between the two phases, the particle will be stable either in one of the two phases or at the interface[10].

The system which has been studied in order to apply these phenomena to fractionation of cellular particles is water/a mixture of potassium dihydrogen plus dipotassium hydrogen phosphate, *p*H 7/polyethyleneglycol 4000 ('Carbowax'). At certain concentrations this system will give two liquid phases similar to those systems which have been used for partition chromatography of proteins[11]. Some whole cells and disintegrated cells have been shaken with this system and their partition is shown in Table 1. At the composition I of the system (see Table 1), *Chlorella pyrenoidosa*, for example, goes to the bottom phase. If the system is changed to composition II, most of the cells are found at the interface. This process is reversible. If disintegrated *Chlorella pyrenoidosa* are shaken with the system at composition I, large fragments of the chloroplasts go to the interface, the smaller ones to the top phase, while the cell walls and starch particles go to the bottom phase. If now the bottom phase is separated and the particles in it are shaken with a system of composition II, the cell walls go to the interface. Fig. 5 is a photomicrograph of cell walls isolated in this way.

In the experiment with spinach chloroplasts, a suspension of whole chloroplasts was made by conventional differential centrifugation. The chloroplasts went to the interphase while starch particles and fragments of cell wall went to the bottom phase. Thus particles with similar sedimentation velocities have been separated.

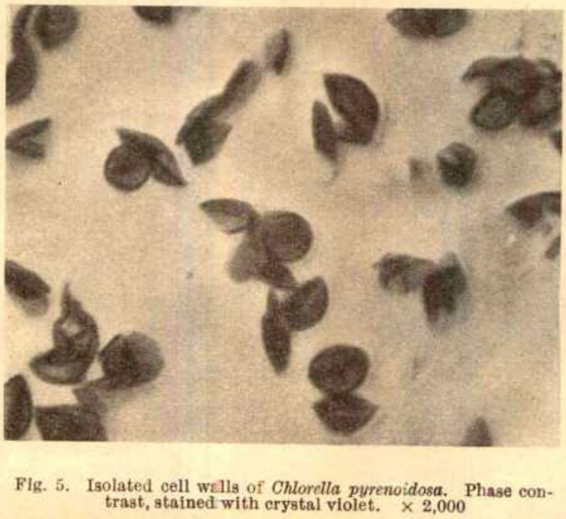

Fig. 5. Isolated cell walls of *Chlorella pyrenoidosa*. Phase contrast, stained with crystal violet. × 2,000

A detailed report of this work will be published elsewhere. I wish to thank Prof. A. Tiselius for his interest and advice. [Feb. 11

OBITUARIES

Dr. F. Sherwood Taylor

The death of Dr. Frank Sherwood Taylor, director of the Science Museum, on January 5, at the early age of fifty-eight, has removed from the scientific life of Great Britain one whose interests transcended the narrow limits of his original specialist studies in chemistry and who had become widely known as a historian of science and as a very skilful expounder of the intricacies of modern science to the layman.

Born on November 26, 1897, Taylor was educated at Sherborne and at Lincoln College, Oxford, where he was elected to a classical scholarship. The First World War interrupted his studies and deflected his interests from classics to chemistry. After graduating, he taught chemistry at various schools, including Gresham's and Repton, and during 1933–38 he was assistant lecturer in chemistry in Queen Mary College, London. In the meantime, he had obtained the degree of Ph.D. in the University of London for his historical researches on Greek alchemy as the first student in the newly established Department of the History and Method of Science in University College. In 1940 he became curator of the Museum of the History of Science, Oxford, where he remained until he was appointed director of the Science Museum, London, in 1950.

Sherwood Taylor, as he was generally known, was always deeply interested in alchemy and the alchemists; he would spare no pains in attempting to understand the most obscure writers and in trying to explain their words in more familiar and comprehensible terms. It was with the greatest enthusiasm, therefore, that he took a most active part in founding in 1937 the Society for the Study of Alchemy and Early Chemistry and in acting as honorary editor of its journal, *Ambix*, from its first appearance in 1937. A similar enthusiasm marked his support of the British Society for the History of Science when it was founded in 1947, and he served the Society as president during 1951–53.

Apart from many papers in specialist journals, such as *Ambix* and the *Annals of Science*, Taylor wrote extensively on the history of science, on chemistry and on alchemy, and also on religious topics. His earliest books were text-books of chemistry, and these were marked by a clear and attractive style as well as by the high standard of presentation of the material. He will, however, be best remembered for his books on the history of science: "Galileo and the Freedom of Thought" (1938), "A Short History of Science" (1939), "The Century of Science" (1940), "Science Past and Present" (1945), "The Alchemists" (1952), "An Illustrated History of Science" (1955), embodying the Christmas Lectures that he gave at the Royal Institution in 1953, and "A History of Industrial Chemistry" (1955). To the general reader he was also known for his remarkable presentation of modern science in "The World of Science" (1936), a work of more than a thousand pages that has retained its well-deserved popularity after the lapse of twenty years.

In the later part of his life Taylor was received into the Roman Catholic Church. He was always deeply concerned in religious matters, although not given to parade his views. Those who had known him long were aware of a strong mystical element in his thought. His writings on religion include "The Fourfold Vision" (1945) and "Two Ways of Life" (1947). His scholarship, his tolerance, his gentle ways, his regard for science as part of man's cultural heritage will long be remembered. Few of those who recall him will know that he was severely wounded at Passchendaele on October 10, 1917, while serving with an infantry unit of the Honourable Artillery Company, and fewer still know that he was at the time voluntarily taking the place of an older man.

Douglas McKie

Dr. E. W. Gudger

The death occurred on February 19 of Dr. Eugene Willis Gudger, one of the oldest staff members of the American Museum of Natural History; Dr. Gudger would have been ninety in August.

Dr. Gudger was born on August 10, 1866, in the mountain section of North Carolina, the son of a circuit judge. Both his parents were descendants of the British settlers of that area and he was very proud of the fact that the name Gudger had originally been Macgregor. He was educated at southern schools and took his doctorate at Johns Hopkins. He then taught general science, first in a secondary school in Little Rock, Arkansas, where his pupils were little younger than he, and then for twenty-five years in the North Carolina College for Women. For many years he went to reunions of the Little Rock class he had taught, and some of his old pupils there remained his closest friends.

In 1919, Dr. Gudger went to the American Museum of Natural History to edit the third volume of Bashford Dean's "Bibliography of Fishes", and after Dr. Dean's death, in 1928, took on the difficult task of editing the Dean Memorial volumes, and was in charge of the Dean Memorial Library and of the card catalogue which until 1938 continued the Bibliography.

In 1921 he was appointed associate in ichthyology, and in 1935 this title was changed to the regular staff appointment of associate curator of fishes. In 1938 Dr. Gudger became one of the honorary staff of the Department of Fishes, but continued as librarian of the Dean Memorial Library. In 1952, his age and his failing eyesight compelled him to stop work at the Museum and he retired to his former home in Waynesville, North Carolina, where he died.

Dr. Gudger's bibliography was enormous: chiefly articles on odd facts about fishes, old natural history myths and the distribution and habits of the whale shark. He was primarily a library worker, with an extraordinary knowledge of ancient natural history literature. He conducted a vast correspondence on all sorts of topics, ranging from fishes to inaccuracies in magazine illustrations of steam engines. The arrival of his mail and his southern home-town paper brought him to the Museum early every morning before the main doors were open or the corridor lights on.

Dr. Gudger was an impressively tall, rosy-cheeked, silver-haired man with peering, bespectacled blue eyes. Due to his unusual appearance, his determined and emotional personality—as booming in enthusiasm as in anger—his departure from the Museum deprived us of one of our most colourful figures.

Dr. Gudger never married. He is survived by a brother.

F. R. LaMonte

Prof. J. R. H. Whiston, O.B.E.

Prof. J. R. H. Whiston, head of the Applied Chemistry Branch in the Royal Military College of Science, died on February 28 after a short illness.

John Reginald Harvey Whiston was born at Gonalston on January 3, 1893, and attended Nottingham High School during 1902–11, when he obtained an open Exhibition in Natural Science at Jesus College, Oxford, where he obtained a first in chemistry in 1914. During the First World War he served (1914–16) as an officer in the Sherwood Foresters, and from 1916 to the end in the R.F.C. as an experimental officer in the Seaplane Experimental Establishment at Martlesham Heath.

In 1919 Whiston returned to Oxford as a demonstrator in the Jesus College Laboratory, where he worked with the late D. L. Chapman on the hydrogen – chlorine reaction, particularly on the effect of oxygen, and with Sir Henry Tizard on indicator problems. After two further years in Oxford as a research chemist to the British Dyestuffs Corporation, he joined the staff of the Military College of Science at Woolwich in 1922.

The remainder of Prof. Whiston's career was spent in the Royal Military College of Science—he became an associate professor in 1936 and stayed with the College throughout its travels from Woolwich to Lydd, from Lydd to Stoke and from Stoke to its new permanent home in Shrivenham. At first his work was mainly on lubricants and on the improvement of petrols; but later he specialized more on Service explosives, and several government publications, including part of the new Services text-book of explosives, were written by him. In 1946 he was made O.B.E.

Prof. Whiston built up, in the College and outside, a reputation as an outstanding teacher and administrator, and he will be long remembered by the students, more than two thousand in number, who were taught by him. The staff of the College will always be grateful to him for his long labours on their behalf in official negotiations and for his never-failing help and kindness to the junior members. He is survived by his widow, their married daughter, and by two grandchildren.

E. C. Baughan

Mr. John Pryce-Jones

The unexpected death of John Pryce-Jones, so soon after his retirement because of ill-health, came as a profound shock to his many friends. He had been in indifferent health for some time, and early this year he had to undergo a major operation.

Pryce-Jones, who was sixty-two years of age, was born in Pencader, and was educated at Llandyssul Grammar School and the University College of Wales, Aberystwyth. He belonged to an age which thought of university education as a great privilege, and throughout his life he maintained the academic interests of a true scholar while engaged in the chemical and administrative affairs of a prosperous industrial firm. After service in the R.N.V.R. as a meteorologist at Scapa Flow during the First World War, he joined the staff of Reckitt and Sons, Ltd., in 1919, and he remained with Reckitt and Colman, Ltd., until his retirement last September. During this time he became known as a leading expert on the manufacture and uses of ultramarine blue, and in 1950 he was appointed a director of Reckitt's (Colours), Ltd., when that company was formed.

Pryce-Jones was interested in all aspects of the chemistry of ultramarine, and among his fine collection were specimens of many shades. In particular, he was interested in its structure and in the influence of particle size, and he made important contributions to the improvement of the manufacture and application of this unusual material. His interest in lapis lazuli was such that he acquired a deep knowledge of its uses in medieval times, and he had a remarkable knowledge of art, in particular of the pigments used in paintings. He was an accepted authority, too, on oils and paints, and was keenly interested in oil paintings and in methods used in the faking of old masters.

During the nineteen-thirties, Pryce-Jones began to develop his interests in rheology, and his papers in the *Journal of the Oil and Colour Chemists' Association* on this subject were soon recognized as having more than a technical importance. They were, indeed, the beginning of a series of studies in the field of rheology which he continued up to the time of his death, and they constituted a very considerable contribution to knowledge.

Pryce-Jones was especially interested in the various modifications of the phenomena associated with 'thixotropy', and he designed several instruments for their investigation. He was strongly of the opinion that there are two distinct modes of behaviour involved in reversible loss of consistency as a result of shearing, corresponding to lyophobic and lyophilic colloidal conditions, respectively. He differentiated clearly between 'thixotropy' proper and 'false-body', though admitting that these can occur together in mixed systems. His nomenclature was sometimes unusual, but always lucid; for example, he insisted that any measurable rigidity should indicate the use of the term 'gel', the term 'sol' being strictly reserved for liquids. He designed an ingenious 'double Couette' viscometer consisting of two concentric cylinder instruments in series, with which he studied many rheologically anomalous materials. His work as an industrial chemist led him to take as wide an interest in suspensions as in sol–gel systems.

Pryce-Jones was one of the first to observe the phenomenon now generally named after Weissenberg (when a material climbs up a vertical rotating rod), which he characteristically referred to as the

"Mae West Effect". As a result of his work on the thixotropy of honeys from certain floral sources, he became a leading authority on honey in general, and he wrote with considerable insight and knowledge about honey and about bee-keeping.

He was a fascinating lecturer and speaker, and both in Great Britain and abroad he had given lectures to various societies on his different specialisms. He had not only a great facility for explaining intricate problems to specialists, but also the ability of giving a simple, and yet scientifically accurate, picture to the layman. He was an omnivorous reader and bibliophile, and he could always be relied upon to make an illuminating contribution to any discussion.

His passing is a great loss to science, for he did much to stimulate scientific interests, particularly in the East Riding of Yorkshire. He was a former chairman of the Hull Branch of the Oil and Colour Chemists' Association and a past president of the Hull Chemical and Engineering Society.

He will be sadly missed at the meetings of scientific bodies and by his innumerable friends and associates in every walk of life: he was perhaps the perfect mixer.

He married, in 1921, Miss Helen Bune, who survives him. Their only son was lost in a tragic accident some years ago.

Paul G. 'Espinasse
Brynmor Jones

NEWS and VIEWS

Geological Survey of New Zealand: Dr. L. I. Grange

Dr. L. I. Grange has retired from the post of director of the Geological Survey of New Zealand. Dr. Grange was born at Castlecliff, Wanganui, and in 1913 he won from Waihi School of Mines a Mines Department scholarship to attend the University of Otago. After war service in France during the First World War and further study at the University, he joined the N.Z. Geological Survey. Dr. Grange's professional career can be divided into three main phases: his work as a volcanologist in the Central North Island, his career as a pedologist culminating in his directorship of the Soil Bureau, and his return to the Geological Survey as director. For the Central North Island his bulletins on the geology of the Tongaporutu–Ohura and Rotorua–Taupo districts still remain authoritative publications. The last-named bulletin is a particularly important contribution to the world's knowledge of thermal activity. As a result of his work on soils, Dr. Grange became leader of a soil survey section of the Geological Survey, and in 1935 he was appointed director of a newly-formed Soil Survey Division. In 1940 he initiated a 4 miles/in. survey of the North Island, and followed this up by applying the results of the survey to practical problems. By 1946 physicists and biologists had been added to the soil team, and the Division was renamed the Soil Bureau. Later he extended his work beyond New Zealand to tropical soils in the Pacific Islands, where soil use in relation to population and food supplies is a problem. In 1952 Dr. Grange returned to the Geological Survey as director. During his term of office he has renewed his early interest in volcanology, and has compiled a departmental bulletin on "Geothermal Steam for Power in New Zealand", which gives a full picture of the work so far carried out in Wairakei. He recognized the probable impact on New Zealand of the important discoveries of radioactive minerals in Australia and after a visit to that country prepared and published a booklet, "Prospecting for Radioactive Minerals in New Zealand". In geology, soil surveys and soil conservation, Dr. Grange has made a notable contribution to New Zealand, and to the welfare of its people.

Mr. R. W. Willett

Mr. R. W. Willett has been appointed director of the New Zealand Geological Survey in succession to Dr. L. I. Grange. Mr. Willett was born in Dunedin in 1912. He was educated at Otago Boys' High School, the University of Otago and the Victoria University College. He joined the Geological Survey in 1936; he served as district geologist at Invercargill during 1942–48, and geologist-in-charge of the Coal Survey Section at Wellington during 1948–51. During 1951–54 he was seconded to the British Commonwealth Scientific Office (London) as liaison officer, and was the first to hold this office. Since returning to New Zealand he has been administrative assistant to Dr. Grange. Mr. Willett has published many scientific papers both in New Zealand and overseas. While in the United Kingdom he prepared a series of papers on the mineral resources of the British Commonwealth, and in 1954 was awarded the Silver Medal of the Royal Society of Arts for his paper on mineral resources of the British Commonwealth. His work in New Zealand has taken him into much of the mountain country of the South Island. He is at present foundation president of the Geological Society of New Zealand.

Zoology at Calcutta: Prof. J. L. Bhaduri

The sudden death of Prof. H. K. Mookerjee in August 1955 left vacant a key post in zoological education in India. This has now been filled by the appointment to the Sir Nil Ratan Sircar professorship and head of the Department of Zoology in the University of Calcutta of Dr. J. L. Bhaduri, a former student of the University. There he graduated B.Sc. with first-class honours in zoology in 1924, and M.Sc. two years later. After two further years, as teaching assistant, in the Zoology Department, he joined the Zoological Survey of India in 1929, and gained valuable field experience, under the guidance of Dr. Baini Prashad and the late Dr. S. L. Hora, in faunistic surveys in the Andamans and in studies of the frogs and toads of the Khashi Hills in Assam. In 1933 he was recalled to his old University as assistant lecturer, and there with increasing responsibility he has combined his recognized skill in teaching with enthusiasm for research. Dr. Bhaduri's main investigations have been concerned with Amphibia Salientia, their systematics, structure and ecology. He studied for two years in the Zoology Department of the University of Edinburgh, and the thesis on "The Urinogenital System of Salientia", for which he obtained the degree of D.Sc. in that University in 1947, contained, among other matters, a revealing correlation between structural modifications in the genital system and unusual breeding habits in certain species which no longer deposit their eggs in water. His latest field survey (1954) has been a special study of the Salientia in the region of the Western Ghats. Apart from his amphibian researches, he has published papers dealing with mollusca, fishes, reptiles and birds. With his forceful personality, boundless energy, and enthusiasm for teaching and research, the appointment of Dr. Bhaduri promises well for the future of zoology in the University of Calcutta.

Zoological Society of London: Mr. R. N. Fiennes

Mr. R. N. Fiennes, senior lecturer in animal health and veterinary science in the University College of the Gold Coast, Achimota, has been appointed animal pathologist to the Zoological Society of London, and is expected to take up his new duties in September. Mr. Fiennes will be responsible for the post-mortem examination of animals which die in the Zoological Gardens, and he will also carry out research in animal pathology. Mr. Fiennes was educated at Winchester and Magdalene College, Cambridge, and at the Royal (Dick) Veterinary College at Edinburgh, and served for some twenty years in the Colonial Veterinary Service, in Uganda and Kenya. He has published a number of papers on trypanosomiasis, and has also worked on other protozoans, on helminths, bacteria and viruses. His appointment is yet another indication of the importance which the Zoological Society places upon the scientific study of animal health.

New Fellowship at University College, Oxford

In 1954 Mr. James George Weir, C.M.G., C.B.E., gave to University College, Oxford, £25,000 to found a fellowship in memory of his son, Colin Weir, to be devoted to the study of politics with special reference to international affairs. He has now presented to the College a further sum of £25,000 to found an additional fellowship which will be devoted to the study of one of the natural sciences. The fellowship may be given for purposes of teaching or research, or both, and will be known as a Weir Fellowship. The College intends to make an election, if possible, in time for the next academic year.

Swimming-Pool Reactor at Harwell for the Study of Shielding Problems

A research reactor of the 'swimming-pool' pattern, named LIDO, is at present under construction at the Atomic Energy Research Establishment, Harwell, and a model of it is included in the display by the United Kingdom Atomic Energy Authority at the British Industries Fair in Olympia, London. The reactor is specifically designed to enable shielding problems to be investigated; hitherto relatively little effort has been made to minimize shielding size and weight, although this is a problem of great importance in the design of mobile reactors and also in keeping down the capital cost of power-station reactors. LIDO is of the thermal type, employing enriched uranium as fuel and light water as both moderator and coolant. The core is suspended in a tank of water from a trolley which enables it to be moved to any part of the tank. Sufficient depth of water is maintained over the core to provide vertical shielding, and horizontal shielding is effected by the concrete walls of the tank. In two areas, one of which is a corner of the tank, the concrete is cut away and replaced by aluminium 'windows'. These form the working faces to which experiments can be built up adjacent to them on the outside, and when measurements are to be made, the core can be moved closer to them on the inside. Experiments can also be assembled inside the tank, and for this the core can be moved into a small bay at one end of the tank and isolated from it by a watertight door. The reactor is due to be completed towards the end of this year.

International Geophysical Year

During the forthcoming International Geophysical Year (July 1957–December 1958) certain days have been designated as Regular World Days, and during these periods special observations will be made at frequent intervals. In addition, there will be Special World Intervals, chosen at shorter notice, to coincide with expected unusual magnetic, ionospheric and auroral activity, etc In order to estimate how many organizations wish to be sent the 'alert' signal so that they are ready to make special observations of any unusual phenomena, it is requested that the names, addresses and telephone numbers of the persons directly responsible for the measurements, in Great Britain and Colonies, should be sent to the Assistant Secretary, Royal Society, Burlington House, London, W.1, as soon as possible, so that the matter can be considered by the British National Committee for the International Geophysical Year.

Marlow Medal of the Faraday Society

The Faraday Society has instituted a new award, to be known as the Marlow Medal, which, together with a grant of not more than fifty pounds, will be made annually for work over the preceding three years on any subject normally (but not necessarily) published in the *Transactions* of the Society. The Medal is restricted to members of the Faraday Society not more than thirty-two years of age. Applications for the first award should be made before January 1 next to the Faraday Society, 6 Gray's Inn Square, London, W.C.1.

Atoms for Peace Awards

Last year, at the suggestion of Mr. Henry Ford II and his two brothers, the Ford Motor Company Fund made an appropriation of a million dollars to be used for granting each year for ten years an Atoms for Peace Award of 75,000 dollars and a suitable medal to an individual or group of individuals, of any nationality, in recognition of the most outstanding contribution to the peaceful uses of atomic energy (see *Nature*, October 29, p. 814). The organization set up for making this Award has recently published a brochure giving the background of the whole idea and the general principles to be followed in making the Award. Nominations for the first such Award are invited. The brochure and further information can be obtained from the Executive Secretary, Atoms for Peace Awards, Inc., 77 Massachusetts Avenue, Cambridge 39, Mass.

Auca Indians

The recent slaying of five missionaries by Auca Indians of eastern Ecuador has aroused concern about the name and nature of these remote South American aborigines. Dr. M. W. Stirling, director of the Smithsonian Institution's Bureau of American Ethnology, states that comparatively little is known about these Indians (*Smithsonian News Release*, February 25). The term 'Auca' does not refer to any particular tribe but is a Quechua term used in the Andean highlands to refer to any pagan Indian groups as contrasted with those who have been converted to Christianity. The group who did the killing belongs to the Zaparo tribe and lives in the area between the Curare and Napo Rivers. The Franciscans, the Jesuits and the Dominicans established a number of missions among them in the sixteenth, seventeenth, eighteenth and nineteenth centuries. Much of what is known is based on the work of Alfred Simson, an Englishman who spent considerable time with the Zaparos in the 1870's.

White interference has been generally disastrous to the Aucas for several reasons, principally because of factors that upset the normal equilibrium of their lives. Among these were the introduction of the white man's diseases and the unhealthy effect of compelling them to wear clothes in a tropical rainforest environment. Although the Indians were normally quite nomadic, they were often compelled to work in the fields and perform other tasks unfamiliar to them. Then, too, they resented interference with their own religion and the attempt to substitute for it ideologies completely foreign to their own background and completely incomprehensible to them. They also found objectionable the suppression of many of their own deeply rooted social habits. The white man's ban on polygamy they found especially intolerable. "Because of the hazards of warfare and hunting there were typically more women than men; thus many women found themselves without a normal home and family life, and the men without the prestige of a large family. Inevitably, the Indians revolted against this restriction on their liberties. In the more remote regions where there was virtually no other white population, as among the Zaparos and Jivaros, these revolts were successful and the mortality among missionaries was high."

The Word 'Protoplasm'

DR. GARRETT HARDIN, of Santa Barbara College, U.S.A., suggests that careful consideration of the term 'protoplasm' indicates that its various meanings are so contradictory and have such uncertain reference to facts that to call the term meaningless is no more than an act of simple charity (*Sci. Mon.*, 82, No. 3; March 1956). In published statements about protoplasm there are many incompatibilities. In some, protoplasm is a substance; in others, a mixture of substances. Sometimes protoplasm is an entity common to all organisms, while at others 'it' is different in all organisms and even in different tissues of a single organism. Hardin believes that the conceptual framework implicit in the word protoplasm has probably impeded scientific progress. Research workers who are most actively engaged in determining the facts to which protoplasm supposedly refers have the least use for the term.

Leaf Morphogenesis

STUDIES of morphogenesis in leaves by E. Njoku are concerned with the effect of light intensity on leaf shape in *Ipomoea caerulea* (*New Phytol.*, 55, 1, 91; 1956). In this paper the author has made a useful contribution to our knowledge of heteroblastic development. Observations are recorded of the changes in leaf shape from node to node in plants of *Ipomoea caerulea* grown under varying intensities of light. These show that the amount of leaf lobing decreases with decreasing light intensity, and lobing is completely suppressed in 0·23 daylight and lower intensities. Plants already producing lobed leaves in full daylight revert to the production of entire leaves when transferred to deep shade, and shade plants producing entire leaves soon begin to produce lobed leaves on transfer to full daylight. There is no correlation between the changes in leaf shape and changes in leaf area, cell size and cell number. The shape of the leaf is determined early in ontogeny and is not appreciably altered during the later growth of the leaf. The effect of light intensity on leaf shape is compared with the effect of length of day reported by Ashby (1950). Length of day has no effect on leaf shape during the vegetative phase of development; but by accelerating or retarding flowering at the apex, length of day exerts a small effect on leaf shape; the leaves just below the terminal inflorescence are usually simpler in shape. The experimental results are discussed with reference to current views on the factors controlling heteroblastic development, and it is concluded that more work is required before the effect of light intensity on leaf shape can be definitely referred to factors as specific as carbohydrate nutrition or auxin supply.

Society of Instrument Technology, Ltd.

THE Society of Instrument Technology, Ltd., has been functioning until recently by the efforts of its honorary officers, and for some time the need has been felt for a full-time staff and permanent headquarters in London. The Society's membership, in all classes, is nearly fourteen hundred, and with the increasing recognition of the need for automation in industry, its activities are growing day by day. An office has now been taken at 20 Queen Anne Street, London, W.1, the headquarters of the Scientific Instrument Manufacturers' Association of Great Britain, Ltd., and a full-time secretary and clerical staff engaged. The secretary is Commander A. A. W. Pollard, who recently left the Royal Navy after more than thirty-one years of service in the Executive Branch. Dr. Harold Moore will continue for the time being as honorary editor of the Society's *Transactions*. All correspondence should be sent to the above address.

Society of Biological Chemists, India

THE Society of Biological Chemists, India, was founded in 1930 and has recently celebrated the first quarter-century of its existence by publishing a "Silver Jubilee Souvenir" (pp. 262; from the Society, Bangalore, 1955). This consists of about fifty short papers contributed by biochemists from many different countries, and the list of authors contains many distinguished names. Some of the papers are descriptions of original work; others are short summaries and discussions of recent discoveries in particular fields of biochemical research. The Society publishes an *Annual Review of Biochemical and Allied Research in India*, and *Proceedings* which summarize the papers read at its ordinary meetings and at its annual symposia. By means of these publications and meetings, the Society helps to co-ordinate the activities of workers in biochemistry in the different parts of India.

Helminthological Society of India

AT the annual general meeting of the Helminthological Society of India, held in Agra on January 3, the following officers were elected: *President*, Prof.

M. B. Mirza (Aligarh); *Vice-Presidents*, Dr. G. S. Thapar (Lucknow) and Dr. H. D. Srivastava (Izatnagar); *Chief Editor*, Dr. G. S. Thapar (Lucknow); *Honorary Secretary and Treasurer*, Dr. B. S. Chauhan (Zoological Survey of India, 34 Chittaranjan Avenue, Calcutta 12); *Foreign Secretary*, Miss N. G. Sproston (Mandapam, Camp); and *Business Manager*, Dr. Kr. S. Singh (Lucknow). At the meeting it was decided to draw up a scheme for a National Parasitological Laboratory in India, and a committee of four was appointed with Dr. Thapar as president and Dr. Chauhan as secretary.

University of London

The following appointments in the University of London have been announced: Prof. E. M. Glaser, professor of physiology in the University of Malaya, to the University readership in physiology tenable at the London Hospital Medical College; Dr. B. C. L. Weedon, lecturer in organic chemistry at the Imperial College of Science and Technology, to the University readership in organic chemistry tenable at that College. The title of professor of genetics in the University of London has been conferred on Dr. Hans Grüneberg, in respect of his post at University College.

The Night Sky in May

New moon occurs on May 10d. 13h. 04m., U.T., and full moon on May 24d. 15h. 26m. The following conjunctions with the Moon take place: May 3d. 04h., Mars 7° S.; May 11d. 20h., Mercury 2° N.; May 13d. 13h., Venus 6° N.; May 17d. 03h., Jupiter 7° N.; May 24d. 09h., Saturn 3° N. Mercury sets at 21h. 30m. and 21h. 05m. on May 1 and 15, respectively, but after this draws too close to the Sun for favourable observation; its stellar magnitude is 0·3 and 2 at the beginning and middle of the month, respectively, the decrease in brightness being due to the decrease in the visible portion of the illuminated disk from 0·450 to 0·098. Venus sets at 23h. 45m., 23h. 30m. and 22h. 35m. on May 1, 15 and 31, respectively. Its stellar magnitude remains almost −4·2 throughout the month, although the visible portion of its illuminated disk decreases from 0·400 to 0·140; this constant magnitude is due to the fact that its distance from the Earth decreases from 98 to 77 million miles, the decreasing distance almost balancing the decreased portion of the illuminated disk. Mars rises in the early morning hours, at 2h., 1h. 30m. and 0h. 50m. at the beginning, middle and end of the month, respectively; it is close to θ Capricorni on May 3, and its eastward motion is easily noticed by comparing its positions with this star over a few nights. Jupiter, visible throughout the night, sets in the early morning hours, at 2h. 20m., 1h. 30m. and 0h. 30m. on May 1, 15 and 31, respectively, and is conspicuous in the constellation Leo. Saturn rises at 21h., 20h. and 18h. 45m. at the beginning, middle and end of the month, respectively, setting in the early morning hours; it lies rather low in the constellation Scorpius but is easily recognized, its stellar magnitude remaining 0·3 throughout the month. No occultations of stars brighter than magnitude 6 occur in May. The η-Aquarid meteors are active in the first week of the month. There will be a partial eclipse of the Moon on May 24, invisible at Greenwich but visible in Australasia; the end will be visible in South Africa. The Moon enters the umbra at 13h. 48·7m. and leaves it at 17h. 13·8m.

Announcements

The Twentieth International Physiological Congress, organized by the Belgian Society of Physiology under the auspices of the International Union of Physiological Sciences, will be held in Brussels during July 30–August 4. An international meeting of pharmacology will be held during the Congress. Further information can be obtained from the secretary of the Congress, Prof. J. J. Reuse, Faculté de Médecine, 115 Boulevard de Waterloo, Brussels.

The eighth of the annual symposia on "Phytopharmacie et de Phytiatrie" will be held in the State Agricultural Institute, Ghent, during May 7–8. Further information can be obtained from the Secretary of the Symposium at the Rijkslandbouwhogeschool, Coupure Links 233, Ghent.

The laboratories and technological sheds of the British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester 22, will be open to visitors on May 10 and 11. There will also be a special open day for textile teachers on July 6, when Mr. L. Gibson and Dr. A. S. Roberts will speak on "Direct Spinning on the Stains Machine", and Dr. J. Mann on "Recent Researches on the Fine Structure of Cellulose".

The Institute of Personnel Management and the National Institute of Industrial Psychology are jointly arranging a five-day course on "The Use of Statistics in Personnel Management", to be held during May 14–18 in the latter body's headquarters at 14 Welbeck Street, London, W.1. The course is designed for personnel officers and others with no previous training in the use of statistical methods and their application to personnel administration. The fee for the course is ten guineas. Registration forms and further information can be obtained from the Courses Secretary, Institute of Personnel Management, Management House, 8 Hill Street, London, W.1.

The Bourke Lectures of the Faraday Society for 1956 will be given by Prof. J. J. Hermans, of the Laboratory of Inorganic and Physical Chemistry, University of Leyden, as follows: May 1, the physical properties of polymer solutions (at 5.15 p.m. in the Physical Chemistry Lecture Theatre, Imperial College of Science and Technology, London); May 3, polyelectrolytes (at 4.30 p.m. in the Chemistry Department, University of Birmingham); May 4, light scattering by solutions (at 5 p.m. in the Nicholson Lecture Theatre, University of Liverpool). The lectures will be open to the public, without ticket. Further information can be obtained from the Faraday Society, 6 Gray's Inn Square, London, W.C.1.

The firm of Shell Austria, A.G., has established two scholarships, each worth about £70 a year, for the study of chemistry or some allied technical subject for six years at an Austrian university. Two more scholarships will be awarded each year so that, from 1960 onwards, there will always be twelve such Shell students. The selection of candidates will be made by Shell in close collaboration with the Austrian Ministry of Education.

Erratum. In the communication entitled "Influence of a Magnetic Field on Thermal Convection Patterns", by W. C Levengood, in *Nature* of March 31, p. 631, the lower part of Fig. 2 has been reversed.

EDUCATION GROUP OF THE INSTITUTE OF PHYSICS

ANNUAL CONFERENCE

AT the annual conference of the Education Group of the Institute of Physics, held in London during April 5–6, the topic on the first day was the teaching of atomic and nuclear physics. On the succeeding day the conference discussed the adequacy of the Advanced Level examinations of the General Certificate of Education as criteria for university selection.

Opening the first session, Prof. P. B. Moon and Prof. W. E. Burcham (University of Birmingham), in a joint paper read by the latter, described the modern physics content of their honours physics courses at Birmingham. At school, the student would have acquired some awareness of the applications of nuclear physics and would use the concepts of atom and electron in chemistry, but with no detailed knowledge of quantum theory. The university course aims at showing the development of modern physics from the basis of classical physics, withholding the more difficult concepts until the student is mature enough to grasp them—quantum mechanics, for example, belonging to the postgraduate courses. The inter-relation of physics with other studies, such as chemistry and engineering, means that the courses must be planned in co-operation with other faculties; and the inter-relations between various parts of physics can provide analogies to introduce modern concepts, since the main difference between atomic physics and ordinary classical physics is simply one of scale. The first year of the honours physics course at Birmingham is a consolidation of school work, without any particular emphasis on physics itself.

The second-year course includes ionization, radioactivity and spectroscopy as an introduction to the Bohr-orbit atom. Descriptive lectures on nuclear physics are given in the third-year, with some advanced lectures on special topics such as luminescence and high-energy machines; and some of the practical work at this stage is done as an assistant to a research team. A good deal of formal instruction is given in the postgraduate courses, during which time the student's capacity for original thinking is developed.

Mr. A. L. Chick (Associated Electrical Industries, Ltd., Aldermaston) spoke of the training of the research worker as an individual, and the creation of a research team as a unit. The modern research laboratory is also a teaching institution, and the lecture courses at Aldermaston include mathematics, electronics, vacuum work, and nuclear physics. Mr. Chick described how a research group convened to design and operate a small research reactor was trained on a project of almost comparable scale, the erection of a Van de Graaff generator and its use on a programme of fundamental research on the spin and parity of nuclear energy levels. While valuable results were obtained incidentally, the real aim was to train the team in the techniques they will apply to the reactor.

The chairman of the Education Group, Dr. J. Topping (principal of Acton Technical College), gave, with his colleague, Dr. J. W. Warren, an outline of the part-time day-release courses at Acton. Among special topics in the syllabus are instrumentation, heat transfer, the use of boiling liquid metal coolants, the properties of materials at high pressures and temperatures, the effects of radiation on materials, the processing of active material, and health physics. Practice in numerical computation and some experimental work are also included. The whole outlook of the course is practical, differing entirely from that given at a university where the ambient atmosphere is one of preoccupation with fundamental research. Indeed, as Dr. Warren added, the only theory really needed is the mass–energy relationship.

The next speaker, Mr. W. O. Peacocke (St. John's School, Leatherhead), then described the work he has been doing with sixth-form boys, using apparatus very largely made by the boys themselves. Given a Geiger counter, a scaling unit and suitable radioactive sources, several good demonstrations to illustrate the historical development of nuclear physics can be presented. The dozen or more class experiments, as performed by boys using microcurie quantities for safety reasons, were impressive in the extreme. Mr. Peacocke, like Joule and Tyndall, is able to relax even amid the rigours of an Alpine holiday and enjoy a little physics; and, having taken his nuclear emulsion plates to a mountain-top, he gave his pupils an excellent project of plate-searching and mosaic-building which produced fine photographs of cosmic ray events. Enterprise of this kind, while enriching the experience of a few fortunate pupils, has a far wider effect in opening the eyes of other teachers to the possibilities available.

Dr. J. M. A. Lenihan (Western Regional Hospital Board, Glasgow) gave his personal impressions of the Geneva Conference on the Peaceful Uses of Atomic Energy. He felt that the participating countries had really laid down their cards, and seemed in fact to have been following almost the same lines independently. In the United States, a long-term programme to discover the most efficient type of reactor is being planned; the U.S.S.R., some way behind, seems urged rather by the propaganda value of the achievement than the actual need for power. Great Britain, he said, urgently needs power to supplement coal resources and is committed to a rather unsophisticated type of reactor to yield results reasonably soon.

The discussion on the adequacy of the Advanced Level examinations of the General Certificate of Education as a guide to university selection was opened by Miss K. E. Parks (North London Collegiate School) and Mr. J. A. Ratcliffe (Cavendish Laboratory, Cambridge). Remarking that the examination was never intended as a university entrance test, Miss Parks suggested that both the syllabus and the number of questions to be answered should be reduced. General fitness for further education might be tested separately, say by means of an essay; and a clearing-house system like that of the teacher-training colleges might simplify matters. Final selection for entry into a special honours course might well be postponed until the end of the first university year; and, whether or not future promise can be assessed beforehand, the actual progress made by a student when he is there depends on the effectiveness of the tutorial guidance at the university. Mr. Ratcliffe also expressed a preference for a shorter syllabus, and a more intelligently searching kind of question. From the point of view of the university, which aims at training people to think, he felt it unfortunate that so many students go up having done physics at school; for they arrive completely misunderstanding the fundamentals, complacently superior towards the important simple things, and loving mathematical proofs for their own sake. After naming specific topics which he would like to see omitted from the Advanced Level syllabus, he said that he regards electricity as the most satisfying part of the work, since it compels a logical treatment; and he noted with interest the Science Masters' Association report on "The Teaching of Electricity", with its logical treatment quite different from the usual historical approach.

During the discussion, Dr. H. R. Lang (secretary of the Institute of Physics) said that physics could certainly be started at the university, and the new transfer scholarship scheme of Imperial Chemical Industries, Ltd. (see *Nature* of March 31, p. 606) would soon be promoting this. This scheme, incidentally, may miss some of the best boys, since those who have never done science at school might be unaware of the satisfactions it offers.

At the final session of the conference a short paper on sandwich diploma courses, by Prof. M. R. Gavin (University College of North Wales, Bangor), explained the aims and organization of the four-year courses that he had inaugurated at Birmingham, the standards expected, and the award to be given at the end. This was followed by some figures on specialization in the sixth forms of grammar schools, collected by Dr. N. Thompson (University of Bristol). He felt that the proportion of the time allotted to specialist subjects was excessive; but schoolmasters in the discussion were divided on the point, since the really relevant matter is the way the remaining time is used.

G. R. NOAKES

ENRICO FERMI AND HIS CONTRIBUTIONS TO PHYSICS

HALF of an issue of the *Reviews of Modern Physics* (27, No. 3, 249; 1955) is dedicated to the memory of the late Prof. Enrico Fermi, one-time president of the American Physical Society, who died on November 29, 1954, and consists of the proceedings of the memorial symposium held at the Washington meeting of the Society on April 29, 1955, over which Prof. H. A. Bethe presided. It contains addresses by F. Seitz, E. J. Konopinski, E. Segrè, W. H. Zinn and H. L. Anderson, together with photographs of sample pages from Prof. Fermi's numerous notebooks which are now being preserved in the Harper Memorial Library of the University of Chicago. The speakers were introduced individually by Prof. Bethe, who referred, in his opening remarks, to Fermi as "unique among the great physicists of the twentieth century in being one of the greatest in experimental physics and at the same time being one of the greatest theoretical physicists. He was unique also in the width of contributions. He may have been one of the last physicists who knew almost all of physics and used it in his research".

Prof. Seitz spoke about Fermi statistics and its applications, and Prof. Konopinski about Fermi's theory of beta-decay, and these two lectures illustrate how two small theoretical articles originally contributed by Fermi to the *Zeitschrift für Physik* in 1928 and 1934, respectively, came to have such tremendous influence on the progress of physics in recent years. Profs. Segrè, Zinn and Anderson deal with different aspects of Fermi's experimental work during the past twenty years. Prof. Segrè gives an interesting description, including many personal reminiscences, of the work on neutrons performed by Fermi and his school in Rome during 1934–35 and for which Fermi was awarded a Nobel Prize in 1938. Early in 1939, just about the time when the news of uranium fission reached America, Fermi arrived in the United States and became engaged on the work—atomic energy—which was to occupy his attention for the rest of his life. Prof. Zinn, in describing the part played by Fermi in the atomic energy project, considers three separate periods: the first, January 1939 to May 1942, when Fermi's work was centred on Columbia University; the second, May 1942 to the winter of 1943–44, when Fermi's work was mainly directed towards bringing about the self-sustaining chain reaction and the construction and operation of the production piles at the Hanford Engineering Works of the Manhattan District; and the third, after May 1944, when Fermi transferred to the Los Alamos Laboratory in New Mexico and finally to Chicago.

In Chicago Prof. Anderson was actively associated with Fermi and was engaged on scattering experiments using intense beams of mesons obtained from a large synchrocyclotron. Prof. Anderson describes in his talk the close personal interest, even to the actual construction with his own hands of several pieces of apparatus and the observation of various instruments, that Fermi took in the experiments. The object of the investigation was to uncover the part that π-mesons play in the nuclear interaction; and though Fermi did not live long enough to see all his predictions verified, his clear understanding of this, in addition to many other similar problems, pointed the way to the present knowledge of the pseudoscalar nature, strong coupling, short-range interaction, charge-independence and causal behaviour of π-mesons.

THE BOSE INSTITUTE, CALCUTTA

THE thirty-eighth anniversary meeting of the foundation of the Bose Institute was celebrated on November 30, when (the late) Dr. Sunder Lal Hora delivered the seventeenth Acharya Jagadish Chandra Memorial Lecture. He chose as his subject "Conflict versus Co-operation as Factors in Evolution".

The director, Dr. D. M. Bose, in his report reviewed the activities of the Bose Institute for the past year. He said that the Institute had submitted to the Central Government plans and estimates for expansion of activities during the second five years. All the plans for expansion of the research activities of the Institute depended on the provision of additional buildings for laboratory accommodation. For this purpose additional land for building purposes is necessary, as there is very little land available in the present location of the Institute. He pointed out that to the west of the Institute the Corporation of

Calcutta has a plot of land lying vacant at present, which he hoped the Corporation may give on lease to the Bose Institute.

The Institute is developing the recently acquired area at Shamnagar as an experiment farm. A donation of Rs. 40,000 from the Government of West Bengal is being utilized for the erection of a laboratory. It is proposed to concentrate at Shamnagar most of the investigations on the effects of different kinds of radiation in producing mutation in plants. So far, only the mutants of economic plants possessing improved economic properties compared to their parents have been isolated and propagated. It is now proposed to devote more attention to the Mendelian characters of the mutant produced. The sources of radiation employed up to now have been X-rays and β-rays from radioactive phosphorus and sulphur. Recently, Dr. K. T. Jacob, head of the Department of Botany, has returned from a scientific tour extending from Sweden to the United States, visiting many of the important plant-breeding stations, where the effects of irradiation on plants growing in fields are studied. The method generally employed is to use a powerful source of gamma-radiations from cobalt-60. The radioactive cobalt, which is produced rather cheaply in atomic reactors, is used in strengths varying from 100 to 200 curies and more. Special techniques for handling such unusually powerful sources are necessary. Experimental plots of size of about 10–15 acres of land are required for field experiments. Dr. Bose expressed the hope that with the co-operation of the Department of Agriculture, West Bengal, it may be possible to undertake such large-scale investigations. This field irradiation method is now recognized as one of the most promising methods of improving crops of economic plants. Besides producing rust-resistant wheat, radiation from cobalt-60 is being employed as an alternative method in storing potatoes. The sprouting of potatoes can be partially to completely inhibited by exposing them to gamma-radiation of total strength varying from 5,000 to 20,000 r. This method of potato storage may ultimately replace the more expensive cold storage method now in use.

Reference was also made to the international co-operative work to be undertaken for the International Geophysical Year 1957–58, in connexion with which the Bose Institute proposes to make continuous records of intensities of different components of the cosmic rays with apparatus installed in the Mayapuri Research Station, Darjeeling.

Dr. Bose also pointed out that in 1958 will occur the hundredth anniversary of the birth of Sir J. C. Bose, the founder of the Institute; he hoped his fellow-countrymen will celebrate the centenary in a befitting manner. He disclosed that on request from the Ministry of Education, the Government of India, he has sent a script on the life and activities of Sir J. C. Bose for the preparation of a documentary film.

RELATIVITY AND SPACE TRAVEL

It has long been evident that the special theory of relativity is very imperfectly understood, even by mathematical physicists of high distinction. More than fifteen years ago, in two articles in *Nature*[1], I directed attention to one type of mistake, and the abundant correspondence that followed, though it showed that some clarification had been achieved, was on the whole disappointing because of the depth and variety of the misconceptions that it revealed. However, no further action then seemed possible, and the only thing to do was to wait for some major error to occur which would force physicists to re-examine their assumptions.

A new factor, however, has now entered the situation. Space travel at high velocity is being regarded as a serious possibility in the not enormously distant future. Sir George Thomson, for example, in his recent fascinating book, "The Foreseeable Future", p. 89 (Cambridge, 1955), discusses a journey to the nearest star and back in just over seventeen years by terrestrial clocks. He states, however, that owing to "the relativistic contraction of time", the travellers would have "aged" by only 14½ years, and adds the following footnote: "The bearing of the relativistic contraction of time on this problem has been questioned, since it leads to an apparent paradox, but the best opinion is that the contraction would occur and that the returning astronaut would, in fact, find that time had gone more rapidly on the earth than on his space ship".

There could be no stronger confirmation of the misunderstanding to which I have referred than the fact that, fifty years after Einstein's clear and logical paper[2], this can be called a matter of "opinion". It is still more serious that the "best" opinion can be regarded as that which is simply a direct denial of the principle of relativity, but of that hereafter. The point to notice at the moment is that the question is no longer an academic one; it has become a matter of profound social and philosophical importance, no matter whether space travel is imminent or not. It needs little imagination to see that if the public is led to believe that there is scientific sanction for the idea that it is *possible* to postpone the date of one's death by space travel, some very undesirable consequences might ensue. It is therefore necessary to bring the matter forward again, so that there shall no longer be differences of opinion on a matter of straightforward logic.

The calculation by which Sir George Thomson arrives at the figures quoted above is based on a formula given by Prof. W. H. McCrea[3] in a discussion of the famous 'clock paradox'. Two observers, M and R, separate and then re-unite at uniform linear velocity. The clock of the moving one will run slow, and so will be behind on reunion. But since either can be supposed to have moved, M's clock will be behind R's and R's behind M's, which is impossible. McCrea purports to show that, in fact, on reunion M's clock will be behind R's by an amount $2T(1 - \alpha)$, where T is the time of the one-way journey at uniform velocity V, and $\alpha = (1 - V^2/c^2)^{1/2}$, c being the velocity of light.

One possible difficulty can be removed at the outset. McCrea is not concerned with the brief accelerations which must occur at the beginning, middle and end of the journey. Since T is independent of them, it is supposed so great that their effects, if any, are by comparison negligible. The retardation given above, calculated by the formulæ of special relativity alone, is therefore at least a close approximation to the supposed truth.

It is not necessary (though it is not difficult) to analyse McCrea's calculation in order to see that his result must be wrong. It would, in fact, be misleading to do so, for it would suggest that he had made a mathematical error, whereas the error is in the pre-mathematical ideas. The fundamental principle of relativity, in its application to the case of two bodies in uniform relative motion, is simply that the motion is a relation between them and not something belonging to one or the other, so that all its effects, if any, must apply equally to both. If, then, the two clocks in question, which would have continued to agree if they had not separated, show different times on reunion, something must have happened to one which did not happen to the other, and nothing is in question except their relative motion. Hence they cannot show different times on reunion.

But those familiar with the customary phraseology of the theory will ask what is meant by the familiar statement that a moving clock runs slow. How can that be, they will ask, if the clock can equally well be said to be at rest (and so running normally) or moving (and so running slow)? It simply means that its reading is behind that of an imaginary stationary clock at the same place, which is synchronized with the observer's stationary clock. The synchronization of the two 'stationary' clocks is the determining factor; nothing at all happens to the moving clock.

The revolutionary fact that Einstein pointed out in 1905 was that we have no intuitive means of assuring ourselves that two similar clocks at different places are synchronized—or, in other words, that two events happening at different places are simultaneous. Hence we must give up the idea that simultaneity of separated events is a phrase needing no explanation, and choose *by definition* what it shall mean. To be of practical use, the definition must be in terms of some physical process actually performable. We can imagine several such processes; but they all involve some assumption about the passage of light unless we include that passage in the definition.

Einstein therefore defined synchronism as follows. R (stationary) regards a clock at X as synchronized with his own when, if he sends a beam of light to that clock and receives it back, the time shown by the clock at X is half-way between the times, by his clock, of emission and return of the light. But this requires that M (moving towards X) will get a different result from the same process. Suppose M, at the time of R's emitting the light, is adjacent to R with his clock agreeing with R's. Then obviously M will receive the returning light earlier than R, and the time which it shows the clock at X to indicate will *not* be half-way between emission and return of the light by M's clock. Hence the clock at X will not be synchronized with M's. We cannot say that, because R is at rest and M moving, R is right and M wrong, for M might equally well retort that it is R who is moving. Hence our definition of synchronism, or of simultaneity, demands that two observers in relative motion will have different ideas of what events, occurring at different places, are simultaneous with one another.

We can now see what happens when our space traveller sets off. Nothing happens to his clock; but to compare it with a terrestrial one you must read them at the same time, otherwise you can get any result you like. The terrestrial observer, choosing what he calls the same moment, finds that the traveller's clock is slow. The traveller, however, says that the terrestrial observer has compared them at different moments; he makes the 'right' choice and finds the terrestrial clock to be slow. Both are right —which would be impossible if the effect were something that happened to a clock instead of to a judgment of simultaneity. When the observers meet again they are both at the same place and relatively at rest. Their judgments of simultaneity agree, and so their clocks agree. All this applies also to heart-beats. The observers will have 'lived' the same time and made the same progress towards the tomb.

What I have written here is simply a paraphrase of Einstein's original paper on the subject. After all allowance has been made for the mental effort required to discard deeply rooted prejudices, it is impossible after fifty years to justify the wholesale abandonment of even elementary reasoning which physicists have allowed themselves to sanction. This outstanding triumph of reason over prejudice has been distorted into a triumph of magic over reason, and the state of mind thus engendered exposes us to dangers which it is impossible to exaggerate. I first directed attention to it nearly thirty years ago and have done so at intervals since[4]; yet the mistaken interpretation of the FitzGerald contraction and clock retardation persists. It is necessary to give a few examples.

Prof. P. S. Epstein[5] makes a relayed appeal to authority, a device that became unscientific at the close of the Middle Ages. Dr. R. A. Millikan had told him that H. A. Lorentz had said that the FitzGerald contraction was "no less real than . . . the variations that are produced by changes of temperature". The meaning of this depends, of course, on what one means by "real", but, whatever that may be, the quotation is irrelevant since it misses the essential fact that if one of two equal rods is cooled, that one unambiguously contracts, whereas if one is moved, you can equally well say that it or the other has "contracted". Prof. L. Infeld[6] tries to save the situation by claiming that a journey covering an exact number of hours will show that a moving clock has slowed down; but if the minute hand has to be read also the whole test becomes meaningless. He adds, however, that the matter cannot be fully elucidated without reference to the social attitude which the physicist takes. Prof. McCrea[7] has to say that his observer M sees that R, after reaching a distance αX, " 'cheats' by rushing out to distance X and back again to distance αX in negligible time". Cheating indeed! In Sir George Thomson's example light would take a little more than a year to cover the distance which M sees R cover in negligible time.

I know of no other example in the history of science in which such fantastic propositions have been put forward as sober scientific truth. The theory of relativity is unique, not merely in its difficulty, which is solely one of discarding prejudices and is excusable, but in its paralysing effect upon the reason, which is not excusable. It looks as though the reaction from excessive rationalism that marked the beginning of the modern scientific era has gone too far, and that a course in traditional logic should be included in the training of all science students. Physicists should not have been misled by such words as 'contraction' and 'retardation' into supposing that the objects said to experience these effects suffer changes analogous to those produced by lowering temperature or by lengthening a pendulum. Sooner or later the lesson will have to be learnt. Let us hope that it will be before some patriarch embarks on a trip to the Andromeda nebula in an attempt to outlive his great-granddaughter.

One other point must unfortunately be mentioned, as it will undoubtedly be raised if this article has the desired effect of making readers turn to Einstein's paper. That paper contains a most regrettable error, in a statement that a clock moving in a closed curve will be found, on returning to its starting point, to be behind a stationary clock. That this is an error there is no question, for such a motion is continuously accelerated and with such motions the special theory of relativity is powerless to deal. But in fact the result given did not follow even from the special theory. At that stage, when Einstein was introducing a fundamental modification of physical theory, he did not concern himself with details of mathematical rigour, which could be left for later investigation, and he wrote: "We assume that this definition of synchronism is free from contradictions, and possible for any number of points; and that . . . If the clock at A synchronizes with the clock at B and also with the clock at C, the clocks at B and C also synchronize with each other". We know now that this assumption is only partially valid; two Lorentz transformations in different directions do not commute. Consequently, the theory cannot be applied to motion in a polygon and then extended to a closed curve. This incidental passage in Einstein's paper has therefore no relevance to the present problem.

HERBERT DINGLE

[7] *loc. cit.*

PROF. DINGLE's exposition of relativity theory is wrong and a plain reply is needed.

Consider the example given by Sir George Thomson and quoted by Dingle. For definiteness, suppose Thomson's traveller starts from rest on the Earth, visits the nearest star and comes to rest on it, then returns so as to come to rest again on the Earth. The traveller needs some form of engine in order to gain speed at the start of his journey, to stop himself at the star, to gain speed for his return journey and, finally, to stop himself at the Earth. Over most of his journey, his engine may be cut out. His path, while his engine is cut out, we shall call a free path. His career from any time before his departure to any time after his return consists essentially of four free paths: a free path with the Earth until he leaves it, a free path most of the way to the star, a free path most of the way back, and again a free path with the Earth after returning to it. These do not add up to a single free path: no matter how long the man waits on the Earth without switching on his engine, he will not find himself on the way to the star, nor, without again using his engine, will he ever find himself on his way back again. Nevertheless, the duration of the journey does not depend essentially upon the duration of the parts when the engine is in use. The same uses of the engine would equally well enable the man to visit the star were it, say, a million times farther away.

On the other hand, the career of a second observer who remains on the Earth is a single free path.

This distinction between the two observers is an *absolute* distinction. That it is so is shown by the simple fact that one of the men has to use an engine and the other not. This common-sense distinction cannot, of course, be removed by any 'principle of relativity'. Even if the traveller chooses to regard himself as at rest and the Earth as departing and returning, it is still he and not the man on the Earth who has to use the engine. Therefore, no mere appeal to a principle of relativity enables us to say whether or not the two men agree as to the duration of the journey.

In particular, there is no relevance in saying, as Dingle does, that nothing has happened to the traveller's clock and so it must show the same time as the clock on the Earth. The question is not, What has 'happened' to the clocks? It is, What have the clocks measured? Dingle's statement that the clocks must agree has no more validity than a statement that the milometers of two cars that take different routes to the same place should agree as to the distances travelled.

The answer given by the theory of relativity is very simple. For what we have been calling a free path corresponds in relativity theory to a segment of a geodesic world-line. The world-line of the observer on the Earth is a geodesic; the world-line of the traveller is not a geodesic (though it can be made up of parts of four different geodesics). In the case of this kind of geodesic, the geodesic interval between two events is the longest interval between them (not the shortest as in some other cases). The interval or proper-time, in accordance with the theory of relativity, is what is measured by a clock having the same world-line. Therefore, the clock on the Earth records a longer time than the clock carried by the traveller. This is the result given by Thomson and is a strictly correct inference from relativity theory. (The above argument is sufficient for the simple case considered. In other cases, the geodesic need not give the longest interval except in comparison with neighbouring world-lines between the same two events, and the geodesic need not be unique.)

Regarded geometrically, Dingle's assertion that the clocks must agree is equivalent to saying that the interval between two events or the distance between two points in four dimensions is the same along every path joining the events or points. His assertion would require relativity theory, in the accepted sense, to be rejected and the universal time of classical theory to be reinstated. It is, in fact, evident that Dingle still believes such a time to exist. Otherwise his contention that "you must read them [the clocks] at the same time" is meaningless.

Dingle's "paraphrase" of Einstein's paper is a travesty. He purports to explain special relativity without once mentioning the all-important postulate of the existence of inertial frames of reference. So far as what Dingle is trying to explain is concerned, Einstein was considering only observers at rest in inertial frames. For present purposes, these are equivalent to observers whose world-lines are geodesics.

In my example of the clock paradox, observer *R* remains at rest in an inertial frame, that is, he remains in a free path; observer *M* transfers from one inertial frame to another, that is, he transfers from one free path to another and these different free paths do not combine into a single free path. Once again, this is an absolute distinction between *R* and *M*.

My purpose was to point out how this absolute distinction results in a distinction between the ways in which *R* and *M* describe the relative journey. Therefore, the usual relativistic result cannot, in fact, be made to yield a paradox. My purpose was not to re-establish the usual result. Had it been, I need only have remarked that two curves with the same end-points in general possess different lengths. But it is this obvious result that Dingle now denies.

In spite of what Dingle writes, physicists and mathematicians are quite certain about what follows rationally from the postulates of relativity theory. What no one can be certain about in the same way is the extent to which the actual universe conforms to the postulates. By reason of the many tests of the theory, most of us are convinced that the theory can be correctly applied to the phenomena here considered. However, Dingle might be entitled to question this applicability. What he is not entitled to state is that someone else's calculations "must be wrong" for unspecified reasons.

W. M. McCrea

Berkeley Astronomical Department,
University of California.

Prof. McCrea wanders widely from the point, and I do not propose to follow him. Of course. the traveller must be accelerated in order to start, turn and stop again, and this may infinitesimally affect his clock. As McCrea agrees, the accelerations may be extremely brief, so the clock cannot lose much time in them or it would go backwards. The 2½ years in question is a function of *T*, the time of what he now calls "the free path", during which the engine is cut out. Hence the "absolute" distinction, arising from the use of the engine, is eliminated. McCrea makes no comment on the remarkable feat of *R* in beating light to a standstill. His remarks about geodesics are a wide and needless generalization of the problem; he has said nothing in answer to the definite statements I made.

One or two minor points in his letter require brief comment. First, he says, "The question is not, 'What has 'happened' to the clocks? It is, What have the clocks measured?" The question is simply, Will one clock differ from the other or not? That is all. What they have measured, if anything, is a metaphysical question; it does not enter the problem.

Secondly, McCrea says that I must believe in the classical universal time because I say "you must read them [the clocks] at the same time". My article stated specifically that "the same time" for one observer was not "the same time" for another, so how can this imply belief in the classical universal time?

Thirdly, McCrea calls my paraphrase of Einstein's paper "a travesty" because I have not mentioned "the all-important postulate of the existence of inertial frames of reference". I have looked through Einstein's paper again, and find that he also fails to mention this all-important postulate: he speaks only of "stationary" and "moving" systems, as I did. This may make his paper a travesty of reason, though I do not think so; but I cannot accept it as a criticism of my paraphrase.

Fourthly (and this, of course, is the really serious aspect of the matter), McCrea says, "physicists and mathematicians are quite certain about what follows rationally from the postulates of relativity theory". How, then, does he explain the number of different solutions of the clock paradox, a few of which he mentioned in his first letter, and how is it that it has been left for him to be the first to discover, after forty-six years, that there is no paradox at all?

Finally, he says that I am not entitled to state "that someone else's calculations 'must be wrong' for unspecified reasons". I claim that my article did specify the reasons.

Herbert Dingle

PERFLUOROALKOXY RADICALS

By D. A. BARR, W. C. FRANCIS and Dr. R. N. HASZELDINE
University Chemical Laboratory, Cambridge

It is reasonably well established[1] that primary alkoxy radicals react either (*a*) by hydrogen abstraction from a molecule *QH*:

$$R\mathrm{CH_2.O}\cdot + Q\mathrm{H} \longrightarrow R\mathrm{CH_2OH} + Q\cdot$$

for example,

$$R\mathrm{CH_2O}\cdot + R\mathrm{CH_2O}\cdot \longrightarrow R\mathrm{CH_2OH} + R\mathrm{CHO}$$

or (*b*) by loss of formaldehyde to give a radical of shorter chain-length:

$$R\mathrm{CH_2.O}\cdot \longrightarrow R\cdot + \mathrm{HCHO}$$

It is now clear that perfluoroalkoxy radicals $R\mathrm{CF_2.CF_2.O}\cdot$ behave somewhat similarly. Such radicals can abstract hydrogen in a manner analogous to that in (*a*) above; in absence of compounds containing hydrogen, however, a disproportionation reaction, for example,

$$R\mathrm{CF_2.CF_2.O}\cdot + R\mathrm{CF_2.CF_2.O}\cdot \longrightarrow R\mathrm{CF_2.CF_2.O.F} + R\mathrm{CF_2.COF}$$

is not observed, and is indeed unlikely, since it would require fission of a C—F bond. On the other hand, loss of carbonyl fluoride, the fluorine analogue of formaldehyde, from such radicals:

$$R\mathrm{CF_2.CF_2.O}\cdot \longrightarrow R\mathrm{CF_2}\cdot + \mathrm{COF_2}$$

appears to be a general reaction in fluorocarbon chemistry, and is illustrated by the following three examples.

(1) Photochemical oxidation of a perfluoroiodoalkane such as C_3F_7I is extremely rapid and yields only carbonyl fluoride and (by attack on the glass reaction vessel) silicon tetrafluoride[2]. Facile breakdown of a perfluoroalkyl group by conventional reagents is usually extremely difficult to achieve, and

the ease of breakdown by photochemical oxidation indicates a novel chain reaction visualized, after taking other evidence into consideration, as follows:

$$C_3F_7I \xrightarrow{h\nu} C_3F_7\cdot \xrightarrow{O_2} C_3F_7\cdot O_2\cdot \xrightarrow{C_3F_7I} C_3F_7.O.OI$$

$$C_3F_7.O.O.I \xrightarrow{h\nu} C_3F_7.O\cdot + \cdot OI$$

$$C_3F_7.O\cdot \longrightarrow C_2F_5\cdot + COF_2$$

$$C_2F_5\cdot \xrightarrow{O_2} C_2F_5.O_2\cdot \xrightarrow{C_3F_7I} C_2F_5.O.OI \longrightarrow C_2F_5\cdot O\cdot$$

$$C_2F_5\cdot O\cdot \longrightarrow COF_2 + CF_3\cdot \xrightarrow{O_2, C_3F_7I} COF_2\ (+SiF_4)$$

etc.

Such a branching chain mechanism, involving formation of perfluoroalkoxy radicals such as $C_3F_7.O\cdot$, $C_2F_5\cdot O\cdot$ and $CF_3\cdot O\cdot$ followed by loss of COF_2 to give a perfluoroalkyl radical of shorter chain-length, makes understandable a reaction that was initially quite anomalous in fluorocarbon chemistry[2].

(2) Heptafluoronitrosopropane is obtained when heptafluoroiodopropane is photolysed in the presence of nitric oxide[3,4]. In the absence of mercury, which removes from the reaction zone the nitrogen dioxide produced by photolysis of nitric oxide, the formation of heptafluoronitrosopropane is accompanied by the production of heptafluoronitropropane and by extensive breakdown of the perfluoroalkyl chain to give carbonyl fluoride and low yields (2–5 per cent) of pentafluoronitrosoethane and trifluoronitrosomethane as well as smaller amounts of the corresponding nitro-compounds. The formation of nitroso- and nitro-derivatives of the shorter-chain radicals C_2F_5 and CF_3 is best explained as follows[4]:

$$C_3F_7I \xrightarrow{h\nu} C_3F_7\cdot + I\cdot$$

Formation of nitroso-compound:

$$C_3F_7\cdot + NO \longrightarrow C_3F_7.NO$$

Formation of nitro-compound:

$$C_3F_7\cdot + NO_2 \longrightarrow C_3F_7.NO_2$$

Formation of nitrite:

$$C_3F_7\cdot + NO_2 \longrightarrow C_3F_7.O.NO$$

Chain degradation *via* alkoxy radical:

$$C_3F_7.O.NO \xrightarrow{h\nu} C_3F_7.O\cdot + NO$$

$$C_3F_7.O\cdot \longrightarrow C_2F_5\cdot + COF_2$$

$$C_2F_5\cdot + NO \longrightarrow C_2F_5.NO$$

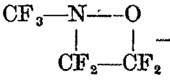
$$C_2F_5\cdot \xrightarrow{NO_2} C_2F_5.O.NO \xrightarrow{h\nu} C_2F_5.O\cdot \longrightarrow COF_2 + CF_3\cdot \xrightarrow{NO} CF_3.NO$$

$$CF_3\cdot \xrightarrow{NO_2} CF_3.O.NO \xrightarrow{h\nu} CF_3.O\cdot \xrightarrow{SiO_2} COF_2 + SiF_4$$

that is, by formation of the nitrite, which undergoes O—N fission to give a perfluoroalkoxy radical; this, in turn, gives a perfluoroalkyl radical of shorter chain-length.

Similar breakdown of the perfluoroalkyl chain is observed when heptafluoroiodopropane is irradiated in the presence of nitrogen dioxide, since $C_3F_7.NO_2$ (38 per cent), $C_2F_5.NO_2$ (7 per cent), and $CF_3.NO_2$ (17 per cent) are produced as well as carbonyl fluoride[4].

(3) Trifluoronitrosomethane reacts with tetrafluoroethylene to give, quantitatively, perfluoro-2-methyl-1 : 2-oxazetidine (I) and a polymer of formula —[$\cdot N(CF_3).O.CF_2.CF_2.$]$_n$— and molecular weight greater than 7,000[4]. Pyrolysis of the oxazetidine, or of the polymer, gives, quantitatively, equimolar amounts of perfluoro(methylenemethylamine), $CF_3.N:CF_2$, and carbonyl fluoride. Heptafluoronitrosopropane and tetrafluoroethylene react in a similar manner[4]. These pyrolyses are readily explained if it is assumed, not implausibly, that N—O fission occurs initially, since carbonyl fluoride elimination from the resultant perfluoroalkoxy radical would be the next step:

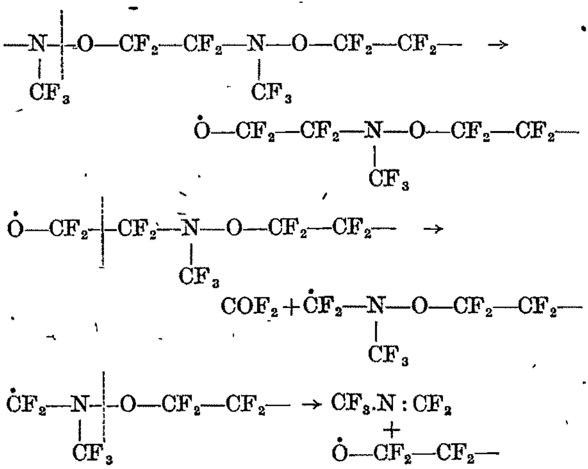


(I)

$$\xrightarrow{550°} CF_3.\dot{N}.CF_2.CF_2.\dot{O}$$

$$CF_3.\dot{N}.CF_2.CF_2.\dot{O} \longrightarrow COF_2 + CF_3.\dot{N}.\dot{C}F_2 \longrightarrow CF_3.N:CF_2$$

and similarly



$$-\underset{\substack{|\\ CF_3}}{N}-\mid-O-CF_2-CF_2-\underset{\substack{|\\ CF_3}}{N}-O-CF_2-CF_2- \rightarrow \dot{O}-CF_2-CF_2-\underset{\substack{|\\ CF_3}}{N}-O-CF_2-CF_2-$$

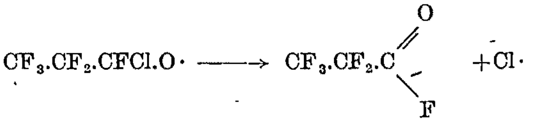
$$\dot{O}-CF_2-\mid-CF_2-\underset{\substack{|\\ CF_3}}{N}-O-CF_2-CF_2- \rightarrow COF_2 + \dot{C}F_2-\underset{\substack{|\\ CF_3}}{N}-O-CF_2-CF_2-$$

$$\dot{C}F_2-\underset{\substack{|\\ CF_3}}{N}-\mid-O-CF_2-CF_2- \rightarrow CF_3.N:CF_2 + \dot{O}-CF_2-CF_2-$$

It does not follow from the above three examples that all perhalogenoalkoxy radicals will decompose by elimination of COX_2. There is already some evidence[2] that when chlorine or bromine is present as well as fluorine on the carbon next to the oxygen atom, a chlorine or bromine atom is expelled in preference to carbonyl halide elimination; for example[2],

$$CF_3.CF_2.CFClI \xrightarrow{h\nu} CF_3.CF_2.CFCl\cdot \xrightarrow{O_2} CF_3.CF_2.CFCl.O_2\cdot$$

$$CF_3.CF_2.CFCl.O_2\cdot \xrightarrow{CF_3CF_2CFClI} CF_3.CF_2.CFCl.O.OI \xrightarrow{h\nu} CF_3.CF_2.CFCl.O\cdot$$



$$CF_3.CF_2.CFCl.O\cdot \longrightarrow CF_3.CF_2.C(=O)F + Cl\cdot$$

so that breakdown of the chain is prevented and products useful for synthesis can thus be obtained. Doubtless other modes of decomposition of these reactive and useful poly- and per-halogenoalkoxy radicals will be found.   [Dec. 14

Genetic Effects of X-Rays in Relation to Dose-rate in *Drosophila*

VARIATION in dose-rate has generally been observed to be ineffective in determining the incidence of mutations and structural changes produced by X-rays in *Drosophila* spermatozoa[1]. However, since it is now clear that a considerable fraction of the genetic damage brought about by radiation results from an indirect path of action, intensity effects might be expected to operate under certain conditions. Chemical mutagens induced by radiation must have a finite life-span before they are removed or rendered ineffective by one or another metabolic pathway. Therefore very high dose-rates, leading to an accumulation of mutagens, should effect a greater amount of damage as a result of diffusion of the active substances to other regions within the nucleus. Sobels's observations[2] that pretreatment with cyanide or azide increases the yield of sex-linked lethals obtained from irradiated *Drosophila* males suggests that the accumulation of chemical mutagens can be facilitated by the concurrent use of suitable enzyme inhibitors.

Haas *et al.*[3] have indeed reported recently that they observed an intensity effect while studying the production of translocations in *Drosophila* sperm. Using dose-rates of 100 r./min. and 2,000 r./min., we have been able to confirm that, for a given dose, a greater amount of genetic damage is produced if the radiation is delivered at high intensity. With a total dose of 2,000 r., the high dose-rate gives an increase of up to 25 per cent in the yield of recessive sex-linked lethals and of translocations. If, just prior to irradiation, the flies are injected with 0·005 *M* sodium azide in saline, the intensity effect is enhanced. The figures in Table 1 illustrate the effects of such an injection on the production of sex-linked recessive lethals by 2,000 r. of X-irradiation delivered to spermatozoa within the spermathecæ of inseminated females.

An especially interesting feature of high-intensity treatment is the production of numerous F_1 females that prove to be mosaics for a sex-linked lethal. By subculturing a single female from those F_2 cultures which fail to yield a lethal, a further crop of mutations may be obtained in the F_3 generation at a frequency of about one-tenth that observed in the preceding generation. This delayed appearance of lethals recalls the similar effects produced by chemical mutagens such as mustard gas[4]. Delayed mutations may also be obtained by mating males that have received high-intensity radiation to attached-*X* females and then crossing the F_1 males to Muller-5 females in the usual way. It should be emphasized that such delayed effects are quite rare if the same dose of radiation is administered at an intensity less than 1,000 r./min. Further study is needed before it can be decided whether the lethals recovered in the F_3 generation are really instances of delayed mutation or whether they are the result of partial breakage of a multi-strand chromosome, followed by sorting out of a mixture of broken and unbroken chromonemata.

Table 1. SEX-LINKED LETHAL MUTATION-RATE

Dose-rate	Inseminated females received 2,000 r. preceded by an injection of 0·2 μl. of:	
	0·7 per cent NaCl	0·005 *M* NaN_3 in 0·7 per cent NaCl
100 r./min.	6·3% ± 0·8	7·6% ± 1·0
2,000 r./min.	8·4% ± 0·6	13·1% ± 1·2

Table 2. PRODUCTION OF HYPERPLOID FEMALES

Treatment	Total No. females	Hyperploids	Standard error	*P*
A	1,875	1·07%	0·24	
B	1,718	1·16%	0·26	= 0·3
C	1,772	1·52%	0·29	< 0·01
D	2,316	0·52%	0·15	

A, undivided dose; *B*, four equal fractions, 1 min. between each; *C*, four equal fractions, 5 min. between each; *D*, four equal fractions, with a 30-min. interval between each. Temperature, 16° C. Total dose, 4,000 r.

In an attempt to estimate the duration of life of the active substances produced by the high-intensity irradiation, fractionation experiments were carried out with varying time-intervals between successive treatments. The experiments were scored by recording the proportion of hyperploid females obtained from a single 24-hr. mating of attached-*X* females (homozygous for the recessive gene, yellow) to Canton *S* males that had received a total dose of 4,000 r. delivered at high intensity (Table 2). At a temperature of 16° C., division of the dose into four equal fractions does not reduce the incidence of hyperploids obtained unless the time-interval between successive doses of radiation is more than five minutes. The critical time-interval would, of course, be expected to be related to the magnitude of each fractional dose, but clearly the effects may persist long enough for further experimental analysis to be practicable.

Full details of this work will be published elsewhere.

A Ventral Ectodermal Ridge of the Tail in Mouse Embryos

THE limb buds of mammalian and avian embryos show a thickening of the ectoderm on the margin of the foot plates, the so-called apical ectodermal ridge, and it is known that this ridge plays an important part in the growth and differentiation of the limbs[1,2]. It has recently been discovered that a similar thickening of the ectoderm is present on the ventral side of the tail in 10- and 11-day old mouse embryos. In 10-day old embryos (crown-rump length 3·4–4·2 mm.; lens invaginations still widely open), there occurs a very conspicuous zone of columnar epithelium on the ventral aspect which extends from the very tip of the tail in a proximal direction for roughly 250 micra; the exact length of the zone is difficult to determine as it gradually disappears

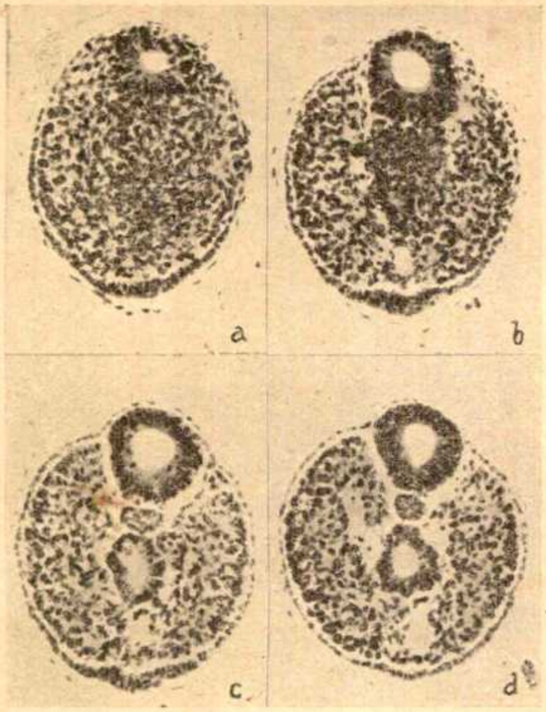

Fig. 1

proximally. The accompanying photomicrographs (Fig. 1) are four transverse sections through the tail of such an embryo (crown-rump length 4·1 mm.; Bouin fixation; hæmatoxylin and eosin; 7·5 micra; × 125) at intervals of about 68 micra; (*a*) is the most distal and (*d*) the most proximal of these sections. The columnar zone of epithelium is obvious in the first three sections but has disappeared in the fourth. In 11-day old embryos (crown-rump length 5·3–5·7 mm.), the structure is rather less conspicuous, and in one out of three such embryos it occupied a position somewhat proximal to the tail tip. In 12-day old embryos the structure has virtually disappeared.

In 9- and 9½-day old embryos (crown-rump length 2–3 mm.), the origin of the ventral ectodermal ridge is traceable to the cloacal membrane. Where entoderm and ectoderm are in direct contact, the latter assumes a columnar structure. Soon afterwards, as the tail bud elongates, the columnar zone spreads in a distal direction; the continuity between ventral ectodermal ridge and cloacal membrane is lost in embryos of about crown-rump length 3 mm.

That the ventral ectodermal ridge of the tail may have a function comparable to that of the apical ectodermal ridge of the limb buds is suggested by the following fact. In the recessive mutant vestigial-tail (*vt*) in the mouse[3], there is almost no tail in the adult except for a short stump or a thin filament. A rudimentary tail (which disappears again later in development) is present in 10-day old embryos, but this rudimentary tail of vestigial embryos has a greatly reduced ventral ectodermal ridge. The situation thus seems similar to the gene for wingless in the domestic fowl[4], where the apical ectodermal ridge of the anterior limb buds is missing or greatly reduced.

There exists in the mouse a type of anomaly which can be brought about by a variety of genotypes, the uro-recto-caudal syndrome[5]; in affected animals, defects of derivatives of the cloaca are associated with reduction or absence of the tail. It may be suggested that cloacal and caudal defects occur together because of the origin of the ventral ectodermal ridge of the tail from the cloacal membrane.

A detailed account of this work will be published elsewhere.

A New Muscle Preparation for the Study of Optical Changes during Contraction

LIVE squid muscle is remarkably transparent. Sereni and Young[1] noted that it becomes more opaque when stimulated. We find that in healthy living muscle the increase in opacity is only transient and that even in response to single shocks this phenomenon is visible to the naked eye. It is therefore easy to record, and thus makes squid muscle particularly suited for studies of optical changes during contraction. Such work is now in progress.

Preliminary experiments have been done on board the research ship *Sarsia* with freshly caught animals. After decapitation, removal of the stellate ganglia and of the skin covering the mantle, a rectangular piece of mantle muscle was cut out and pinned securely under sea water in the path of a parallel beam of light. A vacuum photocell mounted about two inches above the muscle recorded on a cathode ray tube the changes in light transmitted in the incident direction. Square-wave stimuli were applied by means of platinum electrodes to nerves innervating the area of muscle under observation. Mechanical changes were recorded isometrically with an *RCA* 5734 transducer. Records could be obtained within three minutes of killing the animal and nerve-muscle preparations remained in good condition for several hours. The threshold for stimulation of the preparation is approximately 0·3 volt, 150 μsec. width.

The opacity changes during a twitch are shown in Fig. 1, together with electrical (muscle action potential) and mechanical (tension) changes. About 30 per cent more of the light is scattered at the peak of the twitch. At high amplification an initial small decrease in opacity is observed (Fig. 1,*a*); it coincides with the falling phase of the action potential (Fig. 1,*b*) and precedes the first sign of tension change. The latency for opacity decrease at room temperature is about 12 m.sec., the peak of the decrease being reached within 22 m.sec., while the first sign of tension change occurs at 19 m.sec. (These values include nerve conduction time.) The early opacity decrease corresponds to a similar phenomenon observed by Hill[2] in frog muscle where it starts at the same time as latency relaxation. However, in squid muscle, we can find no sign of latency relaxation—if it exists it must be less than 10^{-5} of the twitch tension (in frog muscle the early tension drop is about 10^{-3} of twitch tension[3]). The absence of latency relaxation has already been noted in other molluscan muscles[4].

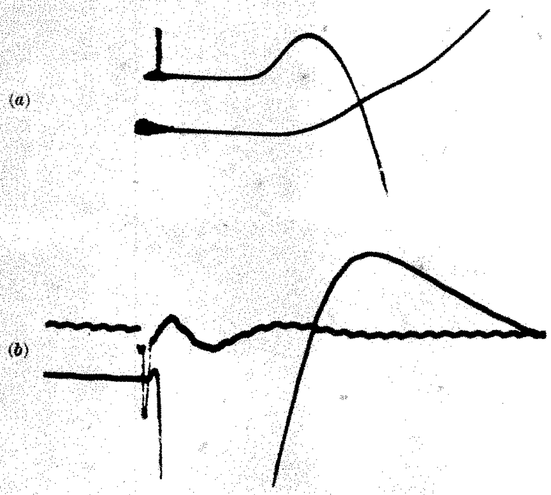

Fig. 1. Responses of squid mantle muscle to single shocks. Records read from left to right. *a*, upper trace: opacity change (increase downwards); lower trace: development of tension (increase upwards). Duration of sweep, 50 m.sec. *b*, upper trace: muscle action potential; lower trace: opacity change recorded at lower amplification than in (*a*). 50 c./s. oscillation imposed on upper trace. (Note that in (*b*) the trace of the optical change at the end of the twitch crosses the base-line: this is an artefact due to recording with a condenser-coupled amplifier)

We are grateful to Prof. A. L. Hodgkin and Dr. R. D. Keynes for directing our attention to the transient nature of opacity changes in squid muscle, and to Mr. F. J. Warren for his unfailing assistance. Part of the electrical apparatus was purchased with a grant from the Royal Society.

Note added in proof. Polar diagrams of the light scattered by resting and active mantle muscle have now been obtained. There is a decrease in transmitted light at angles less than about 15° to the incident direction and the phenomenon is reversed at greater angles.

The early opacity change is not due to diffraction: the muscle is unstriated and shows no regular diffraction bands.

Phospholipid Metabolism of Skin

During work on the metabolism of skin, it was found that a scissors mince of rat skin could incorporate phosphoric acid-^{32}P into the lipid fraction. On completion of the work, our attention was directed to the work of Leonhardi *et al.*[1], who had found no *in vitro* synthesis of phospholipid, and had concluded as the result of this and some *in vivo* feeding experiments that rat skin depended for supplies of phospholipid on the liver via the blood. In view of Zilversmit's[2] comment that "rat skin has been shown to be one of the few tissues that cannot synthesize its own phosphatides *in vitro*", it has been thought desirable to record some contrary observations that have been made. The point is obviously of major importance in the metabolism of skin.

The abdominal skin of male albino rats was mechanically clipped and carefully scraped free from subcutaneous tissue, which has a distinctive pink tinge. A scissors mince was prepared, of which 100–400 mgm. portions were incubated at 34° in Krebs–Henseleit saline containing 10 m.molar substrate and 5 μc. phosphoric acid. Each animal yielded about 1 gm. of mince. At the end of the experimental period sufficient 100 per cent (w/v) trichloracetic acid was added to bring the final concentration to 5 per cent, and the mince was washed thrice more with 5 per cent trichloracetic acid. Two water washes removed most of the acid. Lipid was extracted by either of two procedures: (1) three 1-hr. refluxings with ethanol–ether (3 : 1, v/v), evaporation to dryness in the presence of 1 ml. *M* disodium hydrogen phosphate and re-extraction with chloroform; (2) three 1-hr. refluxings with chloroform–methanol (1 : 1, v/v) followed by a wash with 0·1 *N* hydrochloric acid[3]. The final chloroform extract was made to 10 ml. and portions taken for determination of lipid-phosphorus[4].

The radioactivity of the resulting blue solutions was measured in a liquid counter. In every set of experiments a zero-time control was run, in which the trichloracetic acid was added at the beginning. The fact that the specific activity of the lipid-phosphorus of this control never exceeded 5 per cent of that of the 3-hr. experimental portion with glucose as substrate shows that the procedures effectively removed contaminating acid-soluble phosphorus. The rate of synthesis of phospholipid during the first four hours is shown in Fig. 1, and some results with different substrates and inhibitors in Table 1.

The discrepancy with the *in vitro* findings of Leonhardi *et al.*[1] is difficult to explain. Unfortunately, pressure of other work has prevented repetition of some of the work using their technique, and of any of the *in vivo* work. Consequently a full discussion of their results and conclusions would be out of place, although attention is directed to two points. First,

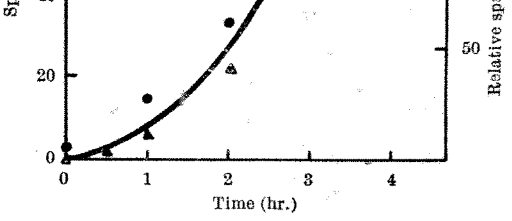

Fig. 1. Time-course of incorporation of phosphorus-32 into rat skin lipids *in vitro*. Specific activities, counts/min./μgm. lipid-phosphorus, uncorrected. Relative specific activities, ratios of specific activity of lipid-phosphorus to that of acid-labile phosphorus (trichloracetic acid extract) of saline medium. Two separate experiments

Table 1. THE SYNTHESIS OF PHOSPHOLIPID BY RAT SKIN *in vitro*

Substrate (10 m.molar)	Percentage specific activity of lipid-phosphorus in 3 hr. relative to glucose
No substrate	69 (87, 59, 62)
Succinate	72 (79, 87, 50)
Glycerol	68
L-Malate	45 (44, 39, 53)
DL-Lactate	52
Acetate	53
Oleate	31 (15, 44, 30, 16, 52)
Palmitate	44
Stearate	42
Glucose, anaerobic	19 (18, 15, 23)
Glucose, iodoacetate (1 m.molar)	11 (6, 15)

the criteria deduced by Zilversmit *et al.*[5] for showing the derivation of a substance from its immediate precursor are not obeyed by the data of their Fig. 2. Hence it is difficult to argue that liver phospholipid is the precursor of skin phospholipid. Secondly, conclusions from an experiment involving the feeding of labelled phospholipid are drawn from observations at a single point of time, 48 hr. Reiner[6] has argued that, in tracer work, observations at a single point of time are often susceptible to more than one interpretation. It seems likely that if Leonhardi *et al.*[1] had not failed to demonstrate *in vitro* synthesis of phospholipid by skin, they could have placed an entirely different interpretation on their *in vivo* experiments.

Enzymic Synthesis and Properties of a Polynucleotide from Adenosine Diphosphate

THE well-known viscous nature of solutions of lysed cells of *M. lysodeikticus*, attributed in part to nucleic acids, led to the search for an active nucleotide polymerase in this organism. Preliminary studies with ^{14}C-labelled adenosine diphosphate (ADP) (the initial paper chromatographic studies were done in collaboration with Dr. Peter Olmsted) and the technique described by Grunberg-Manago and Ochoa[1] revealed the presence of such an enzyme. The present communication deals with the enzymic synthesis and properties of the polymer $(AMP)_n$.

The enzyme has been obtained in a partially purified and highly active form from aqueous extracts of lysed cells fractionated with ammonium sulphate at *p*H 8. The major portion of the activity is associated with the 30–40 per cent saturation fraction. The enzyme activity is determined by measuring the rate of formation of acid-insoluble material or rate of disappearance of acid-soluble material. A typical assay consists of a 2-ml. mixture containing 10^{-3} *M* ADP, 0·025 *M* tris buffer, *p*H 10, 5×10^{-3} *M* magnesium chloride and dialysed enzyme. The reaction is stopped at the end of ten minutes with the addition of 2 ml. of 5 per cent perchloric acid. The precipitate is centrifuged down, washed once with perchloric acid and twice with 95 per cent ethanol, and finally dissolved in 3 ml. of 0·1 *M* tris buffer, *p*H 8·0. The absorption peak of the solution is then measured at 257 mμ. A usual range of optical density values may be from 0·1 to 1·0. A blank which is run for determination of bacterial nucleic acid may be as low as 0·025.

The rate of synthesis of the polymer is proportional to both the enzyme concentration and the ADP concentration, the latter up to 5×10^{-3} *M*. The rate of polymer formation appears to follow zero kinetics until the reaction is more than 90 per cent completed. However, the picture is complicated by the action on ADP of a myokinase and possibly a phosphatase in the enzyme preparation. Chromatographic studies of the reaction mixture consistently reveal a low ATP/AMP ratio. Nevertheless, the results are consistent with the hypothesis that the enzyme has a stronger affinity for the polymer than for the monomer and that once the initial conditions have established the maximum concentration of the polymer, the rate is afterwards determined by the 'product' rather than by the 'substrate'. The reaction will not take place in the absence of magnesium chloride. The *p*H optimum of the reaction depends upon the concentration of magnesium chloride but is greater than 10 at low concentrations. The activation energy over the temperature-range of 8–39° is 11·8 k.cal. at *p*H 8. An apparent equilibrium is in favour of the polymer to the extent of about 70 per cent at *p*H 10 and 37° (it decreases with lower *p*H); but it is independent of enzyme or magnesium chloride concentration. Inorganic phosphate (dipotassium hydrogen phosphate) at concentrations of 0·01 *M* strongly inhibits the polymerization reaction and brings about a rapid decrease in the amount of polymer formed when added to the reaction mixture. The viscosity of the reaction mixture increases at a rate which depends in part on the experimental conditions; but under optimal conditions the viscosity increment may exceed 500 per cent and be only partially dependent upon the amount of polymer formed. Addition of inorganic phosphate brings about a rapid decrease in viscosity. The enzyme preparation is also active with other nucleotide diphosphates in the following order of rates: CDP > ADP > UDP ≫ GDP (no activity at 10^{-3} *M* concentration).

The polymer has been isolated in relatively pure form and subjected to several physical-chemical studies. Its absorption spectrum is similar to that of AMP, but the peak is shifted to 257 mμ and the extinction coefficient is reduced approximately 50 per cent. Addition of a strong alkali such as sodium hydroxide results in a progressive hydrolysis of the polymer associated with a sharp increase in the absorption throughout the ultra-violet range. The polymer readily dissolves in water or alkaline solution to form highly viscous solutions from which gossamer threads can be spun. In a semi-dried state it forms a rubber-like mass which can be stretched to give a well-oriented birefringent structure. X-ray diffraction studies are being made of the spun fibres. The sedimentation coefficient of one preparation at a concentration of approximately 0·007 per cent was 16×10^{-13} at 20°. Electron micrographs show unbranched chains, similar in many ways to those of DNA but irregular in width and smaller in diameter. A Zimm plot of data from light-scattering studies of another preparation showed a molecular weight of $1 \cdot 86 \times 10^6 \pm 20$ per cent with a length of 2400 A. (assuming monodispersed material).

These results should be compared with those previously reported from Dr. Ochoa's laboratory[1,2].

The ease of reversing the polymerization reaction supports the thesis that the primary biological role of RNA may be that of a source of readily available high-energy polyphosphate mononucleotides. The enzyme preparation displays a very strong phosphorylase activity toward the nucleic acid of the bacterium.

This investigation was supported by Research Grant C-2550 from the National Cancer Institute, National Institutes of Health, U.S. Public Health Service. I wish to acknowledge the technical assistance of Mrs. G. Olson in this study and the generous co-operation of the following persons who carried out the work on the polymer: X-ray diffraction studies were under the supervision of Dr. R. S. Bear with Dr. R. S. Morgan; ultracentrifugation studies were made by Dr. D. A. Yphantis; electron microscopy studies were under the supervision of Dr. C. E. Hall; and the light-scattering measurements were made by Dr. R. F. Steiner.

Effect of Pinealectomy on the Rat Pituitary

PINEALECTOMY in rats has been variously reported as resulting in no change[1] or as causing a hypertrophy of the pituitary, with an increase in the proportion of acidophils of the anterior lobe, and some degeneration of the basophils[2].

Blind subdural pinealectomy has been attempted on a small series of young male rats, aged two to four months. Those surviving the operation were killed six to twelve weeks afterwards. Histological examination of the brain confirmed that in eight animals the pineal body had been totally removed, whereas in the remaining seven it was still in its normal position, and apparently undamaged. The pituitary bodies of these two series of animals were fixed in Zenker-formol, sectioned and stained by Pearse's method[3]. Modified Rasmussen[4] cell counts of the anterior lobes were then made, approximately five thousand cells being counted in each gland. The results are shown in Table 1.

These figures show that there is no significant difference between the cellular constitution of the anterior lobe of the pituitary of pinealectomized and non-pinealectomized animals. Successful removal of the pineal did not give rise either to a marked increase in the numbers of acidophils or to basophil degeneration. Colloid formation and development of 'signet ring' forms in the basophils were not significantly increased.

Table 1

	Mean percentages ± mean standard error	
	Pinealectomized	Non-pinealectomized
Acidophils	42·2 ± 1·6	41·3 ± 1·3
Basophils	6·0 ± 0·8	6·6 ± 0·8
Chromophobes	51·8 ± 1·7	52·1 ± 0·8
Percentage of basophils showing colloid formation	4·3 ± 1·6	2·7 ± 1·1

These findings indicate that the pineal body has no effect on the anterior lobe of the pituitary of the young male rat, and suggest that if gonadal changes such as have been reported[5] do occur, they are not mediated via the pituitary.

Incomplete Wound Contracture and the Phenomenon of Hair Neogenesis in Rabbits' Skin

IN rabbits, the healing of extensive wounds produced by excision of the full thickness of the skin of the trunk is the outcome of two distinct, though to some extent overlapping, processes which provide in turn a temporary and a definitive repair[1]. During the course of the first week or two, the defect becomes filled with granulation tissue, which is progressively epithelialized by the migratory ingrowth of epithelium from the wound margins. Closure of the raw tissue surface in this manner marks the completion of temporary repair. The definitive repair is brought about by contracture, a forced inward movement of the wound margins as a consequence of tensile forces generated within the substance of the granulation tissue or its derivatives[2]. Contracture, so it has been shown, is accompanied by a compensatory expansion of the integument surrounding the wound through intercalary or intussusceptive growth[1].

Recent experiments by Billingham and Russell[3] have shown that the process of contracture in experimental full-thickness wounds, ranging in area from about 10 cm.^{2} to 50 cm.^{2} and of various shapes, including rectangles and circles, proceeds at a constant specific rate; that is, obeys the exact opposite of the familiar compound interest law of growth. The logarithm of the area of a wound decreases linearly with time, at least until the wound is not more than a few square centimetres in extent. The actual values of the specific rates of contracture fell within the range 5–8 per cent of the wound area per day. In one series of extensive wounds, 20–40 cm.^{2} in area, produced by excision of the full thickness of the skin down to, but not through, the panniculus on the trunks of thirty-two full-grown rabbits, contracture approached its theoretical end-point so closely in nineteen (that is, about 60 per cent) that only a narrow linear scar remained. In these animals the re-apposition of the skin of the original wound margins was virtually complete. In the remaining thirteen animals, however, the process of contracture terminated abruptly after the areas of their wounds had been reduced to about 5 cm.^{2} or less.

Incomplete wound contracture was also observed in a further group of seven animals, of which three had been adrenalectomized before the excision of their cutaneous wounds, and four received daily administrations of 10 mgm. of cortisone acetate, commencing on the day of operation and continued for at least thirty days. Besides slowing down the rate of contracture, both treatments greatly increased the incidence of incomplete contracture.

Once their contracture had terminated prematurely, the areas of most of the wounds underwent very little change. Their margins remained incisive. In a few animals it was observed that incompletely contracted wounds actually underwent a slow expansion, attaining by about the hundredth day a final area which was approximately double the minimum which contracture had produced by about the fiftieth day.

We have observed that from the smooth, bald surfaces of all incompletely contracted wounds fine hairs begin to emerge, commencing at the periphery, within about forty to fifty days of the operation. The time of appearance of these hairs seemed to depend, among other things, upon the age of the subject: in a group of three animals which were only fifty days old when their wounds were prepared, new hairs had already begun to pierce the surface as soon as the twenty-ninth day. With the production of these hairs the originally smooth scars may be said to have become transformed into a sort of *ad hoc* skin. The hair crop was invariably white in colour, despite the fact that all the rabbits used were of pigmented breeds. The orientation of the hairs borne by these scars bore no constant relation to that of the fur of the adjacent normal skin; the new hairs sloped outwards from the centres of the scars. Comparison of actual counts showed that the hair densities on the scars did not differ significantly from those on neighbouring normal skin. So far as we have been able to ascertain, guard hairs were not included among the newly formed hairs, which, like those of normal skin, were grouped together in small follicle clusters.

The only striking anatomical imperfection of these new hair follicles was their apparent lack of arectores pili muscles. The hairs were medullated and well-developed sebaceous glands were invariably present.

In the preparation of these experimental wounds particular care was taken to remove all trace of the dermis from the surface of the panniculus, including, of course, any embedded follicle bases. When this fact is taken into consideration, together with the large number of new hairs formed (up to 3,500), it leads unequivocally to the conclusion that the hairs were of new formation and could not possibly have been derived from pre-existing follicle remnants. This conclusion is strongly reinforced by their uniform lack of pigment, which is highly suggestive of an origin from the superficial as opposed to follicular epidermis.

The hairs on these uncontracted wounds persisted throughout the entire period of observation, which rarely fell short of a hundred days and frequently exceeded 150 days. Grafting experiments provided further evidence as to the permanence and stability of the new 'skin'. For when small full-thickness grafts were removed from it and transplanted elsewhere on an animal's body, they invariably healed in satisfactorily and regenerated new hairs of the original type.

The new hair-bearing skin was chronically œdematous and slightly inflamed, enlarged blood vessels being particularly prominent in sections; its thickness was about twice that of normal skin; it had a somewhat soft, cheesy consistency when incised, lacking the toughness characteristic of normal skin, and its collagen fibres were mainly disposed in a horizontal plane as is usual in scar tissue.

That the phenomenon of hair neogenesis has escaped notice for so long is probably attributable to the high proportion of wounds which undergo complete contracture and the fact that, even in rabbits whose wounds fail to contract completely, hairs do not normally appear on the scars for many weeks. It may be added that the great majority of previous wound-healing studies have been based on undressed wounds, in which contracture normally takes place much more rapidly and completely, as we have shown[3]. Here the final conditions are most unfavourable for the formation of new hairs. In all the experiments reported on here, the wounds were maintained under dressings at least until they were completely epithelialized and the epithelium was firmly united to its bed and sufficiently robust to withstand the trauma of everyday life. In no animals were the dressings left off before the thirtieth day.

The first unequivocal evidence of the occurrence of hair neogenesis in adult rabbits was presented by Breedis[4], who realized the necessary experimental conditions when he mechanically inhibited the contracture of full-thickness cutaneous wounds by the insertion of appropriately shaped metal splints. Our own findings are in complete accord with his.

Muscular Dystrophy of Beef Cattle and Unsaturated Fats

THE enzootic muscular dystrophy of suckling beef cattle in the north of Scotland[1] can be prevented by administration of α-tocopherol[2]. Analyses of rations which consist mainly of turnips and straw show them to be deficient in tocopherol, and this dietary lack is reflected in extremely low concentrations of tocopherol in the blood serum, colostrum and milk of the cow, and in the blood serum and the tissues of her calf[3]. The quantity of tocopherol necessary for the prevention of the disease in the suckling calf is, however, much higher (twice) than that required by experimental calves given artificial rations simulating milk. Since unsaturated dietary fats such as lard[4] and especially cod-liver oil[5] (a particularly rich source of polyethenoid fatty acids) lead to a gross exacerbation in the incidence and severity of muscular dystrophy and to considerable increases in tocopherol requirement, it was thought that the nature of the dietary fat ingested by the calves in the north of Scotland might be a further factor, in addition to a low tocopherol intake, accounting for the incidence of the disease. This hypothesis was supported by the finding that it was not possible to produce muscular dystrophy experimentally in calves when they were given rations low in tocopherol content but free of fat[6].

Table 1. TOCOPHEROL CONTENT OF COWS' SERUM AND MILK AND ANALYSIS OF MILK FATS

Diet (excluding straw)	Mean tocopherol content of blood serum of cows (μgm./100 ml.)	Mean tocopherol content of milk fat (mgm./gm.)	Iodine value of milk fat	Unsaturated acids in milk fat (mol. per cent)			
				C_{10}–C_{14}	Oleic	C_{18} di- and tri-enoic	As C_{20}–C_{22}
Silage	299	38	41·0	5·2	28·7	1·3	2·3
Silage plus turnips	293	22	36·0	4·6	22·6	1·7	1·9
Turnips	117	4	36·6	7·4	21·0	1·5	0·9
Turnips	94	5	30·4	7·4	16·0	1·5	0·6

The composition of the mixed fatty acids derived from the milk fat of groups of cows in the north of Scotland given rations of turnips and straw was determined by ester-fractionation and compared with that of similar cows in the area given rations containing grass silage. In the latter group the incidence of dystrophy in the offspring is rare. The concentration of polyethenoid fatty acids in the serum lipids of the calves of the cows in the two above groups was also determined according to Wiese and Hansen[7]. Salient information on the composition of the milk fats is given in Table 1.

The low tocopherol content of the blood serum and milk of cows given rations of turnips and straw was not, however, associated with a greater degree of unsaturation of the milk fats; on the contrary, the fats contained less of the unsaturated fatty acids in the C_{20}–C_{22} series and less oleic acid than the milk fats of the cows given silage. There was a corresponding increase in the concentration of saturated acids in the C_4–C_{16} series, especially in respect of palmitic acid.

The concentrations of polyethenoid fatty acids in the blood serum lipids of the calves of cows given turnips and straw were lower if anything than in the serum lipids of calves from cows given silage, as shown in Table 2.

Table 2. PROPORTION OF POLYETHENOID ACIDS IN BLOOD SERUM LIPIDS OF SUCKLING CALVES

Unsaturated acids	Proportion (wt. per cent) of acids in serum lipids of calves, the dams of which were fed on	
	Silage	Turnips and straw
Tetraenoic	3·42	3·45
Trienoic	3·95	3·25
Dienoic	10·23	7·63

There was no indication that abnormal amounts of polyethenoid acids were present in the blood serum lipids of susceptible calves. Experiments with seventy-five calves showed that daily supplements of 20 mgm. α-tocopherol per calf led to slight reductions in the concentration of the unsaturated acids in the blood serum lipids. For calves receiving the unsupplemented ration, the average concentrations (weight per cent) of tetraenoic, trienoic and dienoic acids in the serum lipids were 3·8, 3·7 and 9·1 respectively, and for calves receiving the supplemented ration 3·2, 3·5 and 8·4 respectively. These differences, though they suggest that tocopherol reduces the concentration of polyethenoid acids in the serum lipids, were not statistically significant.

As already mentioned, the importance of dietary sources of unsaturated fat in determining tocopherol requirements in experimental calves is now well established[4-6]. The present work shows that in enzootic muscular dystrophy, the milk fat which the calves receive is less unsaturated than that received by calves which do not usually develop the disease. The fat is, however, grossly deficient in tocopherol content, and this is clearly a more important consideration than the presence of abnormally large amounts of unsaturated fatty acids in accounting for the incidence of dystrophy. The sporadic incidence of the disease, its correlation with muscular exercise and the relatively high tocopherol intakes necessary for complete prevention remain to be explained.

Detailed accounts of this work will be published elsewhere.

Avidity of the Water-soluble Components of Herbage for Added Cupric Ions

DURING work to investigate the availability of organic complexes of copper to the copper-deficient rat, it was found possible to demonstrate the existence of stable copper complexes formed by adding copper-64 ions to the water-soluble components of herbage.

On filter-paper chromatograms developed with phenol/water, a number of complexes of copper with amino- and hydroxy-acids have been shown to have R_F values in the range 0·08–0·98, whereas the R_F of the free cupric ion in this solvent has not been found to exceed 0·06. It is apparent that this technique can provide a useful indication of whether or not the copper in a biological fluid is present as the free ion.

To investigate the effect of adding cupric ions to the water-soluble components of herbage, 2 gm. of freeze-dried grass was extracted with 20 ml. water at 37° C. for 14 hr. After centrifuging at 25,000 *g* for 30 min., 15 ml. of the supernatant was concentrated to 1 ml.

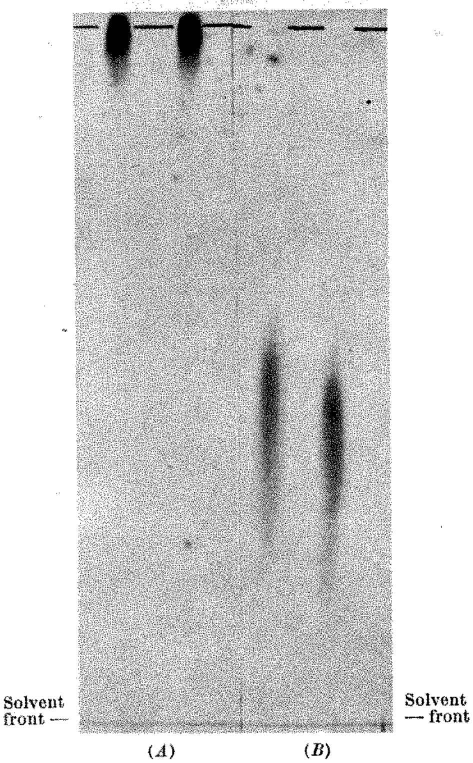

Fig. 1. Autoradiograph of copper-64 chromatograms: (*A*) copper-64 applied to chromatograms as free cupric ion; (*B*) copper-64 applied after combining with water-soluble components of herbage

by freeze-drying and 2·5 μgm. copper-64 + carrier (as copper nitrate) was added. This preparation was applied to Whatman No. 1 filter paper as spots containing 0·012 ml. liquid and the chromatogram then developed with phenol/water as (descending) solvent. Chromatograms containing an equivalent quantity of the untreated cupric ion were developed by the same procedure. Autoradiograph prints of the dried chromatograms on Ilford 'Industrial G' X-ray film were obtained by 24 hr. exposure (Fig. 1).

The absence of a radiation response in the R_F range 0·0–0·06 of the herbage-extract chromatogram indicates that all the added cupric ions have combined to form complexes stable at the solvent pH (4·4) despite the fact that, by this procedure, the copper content of the original extract was increased by two and a half times. The copper complex thus formed has a faint blue-green fluorescence under ultra-violet light, and gives a weak positive response with ninhydrin in butanol.

It is emphasized that, in order to produce a satisfactory autoradiograph, the above chromatograms are overloaded. By the use of more sensitive radiometric scanning methods[1,2], it should be possible to overcome this difficulty.

Field Resistance to Potato Blight (*Phytophthora infestans*)

Two types of resistance of potatoes to blight (*Phytophthora infestans*) have been distinguished—'true resistance' by virtue of hypersensitivity (suprasensitivity) and 'field resistance'[1]. True resistance is not found in the old varieties of European cultivated potato; but it has been bred for on an extensive scale for more than thirty years using the wild Mexican potato, *Solanum demissum*, as the source of genes for the hypersensitive reaction. It appears now that this hypersensitive type of resistance by itself is of limited value, because new physiological races of blight can arise very rapidly to attack clones carrying as many as four different major genes for hypersensitive reactions[2], and because *S. demissum* itself is attacked by blight in Mexico[3]. In contrast, field resistance, which is found in certain varieties of European cultivated potatoes and in other potato species, may be equally effective against all physiological races of blight.

The nature of field resistance was investigated by Müller and Haigh[1] and by Müller[4]. They claimed that susceptible and field-resistant varieties differed in their "probability of becoming infected per unit area of leaf", and they obtained a measure of this probability of becoming infected by spraying the upper surface of small disks of potato leaflets with a weak zoospore suspension and counting the number of disks on which sporangiophores were produced some days after spraying (susceptible and field-resistant varieties showed no differences if the under-surface of the disks were sprayed). Using two varieties, Arran Pilot (very susceptible) and Ackersegen (field resistant), we also were able to demonstrate a small but significant difference between the two varieties in the percentage of disks on which sporangiophores were produced. On the other hand, we were able to show that the disks of Ackersegen on which no sporangiophores were found did contain hyphæ of blight which could be made to produce sporangiophores by placing them on the cut surfaces of potato tubers. It thus appears that the leaflet-disk method measures "probability of producing sporangiophores per unit area of leaf" rather than "probability of becoming infected per unit area of leaf". The disk method also does not appear to be very sensitive, since it was found[1,4] that King Edward and Majestic had similar values for percentage becoming infected, whereas in field observations[5] it has been found that blight on Majestic frequently reaches the 75 per cent stage a week or a fortnight later than it does on King Edward.

Schaper[6] has suggested that field resistance is due to a longer incubation period for the fungus and a lower production of spores by the fungus when it grows on a resistant potato. This we have confirmed for Ackersegen, on which, using either detached leaflets or leaflet disks sprayed with a weak zoospore suspension, sporangiophores are produced one day later than on Arran Pilot, and the number of sporangia

Table 1

Date of inoculation	Date on which sporangia counted	Relative number of sporangia	
		Arran Pilot	Ackersegen
1/10	5/10	46·35	0·00
	6/10	89·60	6·25
	7/10	92·00	25·00
	8/10	102·95	28·15

produced is very much smaller. Details of one experiment are given in Table 1.

It would thus appear that, while susceptible and field-resistant potato varieties may differ in several characters, two of the most important differences, both of which may be due to a relatively slow growth of the fungus in the leaflets of field-resistant varieties, are the length of the incubation period of the fungus and the number of spores produced.

Aphelenchoides sp. destroying Mushroom Mycelium

Damage to mushroom mycelium, by eelworms, leading to diminished crops or crop failures has been known for about fifty years[1]. The eelworms responsible for the damage have been reported as *Ditylenchus* sp. by Lambert, Steiner and Drechsler[2] and by Bovien[3], as *Ditylenchus destructor* by Seinhorst and Bels[4] and as a new species of *Ditylenchus* by Cairns[5]. Cairns[6] has also stated that species of *Aphelenchoides* feed upon, injure and destroy mushroom hyphæ.

Populations of *Aphelenchoides* sp. have frequently been encountered in samples of compost from poorly cropping mushroom beds.

Early this year at Wye, bottles of sterile compost already spawned with mushroom mycelium were inoculated with a mixed population of *Aphelenchoides* sp. and *Panagrolaimus* sp. At the end of four or five weeks the mycelium in the inoculated bottles had largely disappeared, and the population of eelworms had greatly increased. Some of the material was sent to Rothamsted. There one set of pots each containing 300 gm. of compost was inoculated, at the same time as spawning, with fifteen hand-picked specimens of *Aphelenchoides* and another set with fifteen similar specimens of *Panagrolaimus*. A further set of pots constituted a control. Cropping began four weeks later, and continued up to the eleventh week in the control pots and those inoculated with *Panagrolaimus*. In the pots inoculated with *Aphelenchoides* cropping ceased at the end of the sixth week. Examination of the compost showed the reason for these differences. Mycelium was present and undamaged in the control and *Panagrolaimus* series; but in the *Aphelenchoides* series it had largely disappeared. From an original inoculum of fifteen specimens of *Aphelenchoides* there were approximately 3,000,000 present at the end of six weeks. On the other hand, there were only 72,000 *Panagrolaimus*.

The identity of the *Aphelenchoides* is still under investigation. It is not true *Aph. parietinus*, as recently redescribed by Franklin[7]; both sexes are present and there are distinct morphological differences which clearly separate it from this species, although it is similar in many respects.

Control of Seasonal Variation in the Egg Production of Hens

The discovery that artificial light will improve winter egg production by hens is said to have been made about a hundred years ago by Spanish farmers[1]. It was later established in a number of laboratories that it will prevent moulting in pullets brought into lay in the autumn. Little progress has been made in defining the light stimulus except for some experiments on the effect of breaking the night[2]. More than twenty years ago it was suggested on the basis of field records that the seasonal change in day-length as opposed to the absolute day-length was mainly responsible for the seasonal fluctuations of egg yield[3]. This suggestion has never been followed up.

I have tried to examine the effect of the change in day-length in late summer and early autumn on the production of pullets already in lay. Two groups, each of twenty-one Brown Leghorns from an inbred line, were reared from the age of eight weeks, the first in a $23\frac{1}{2}$-hr. and the second in a 12-hr. day-length in artificial light. The birds were kept in

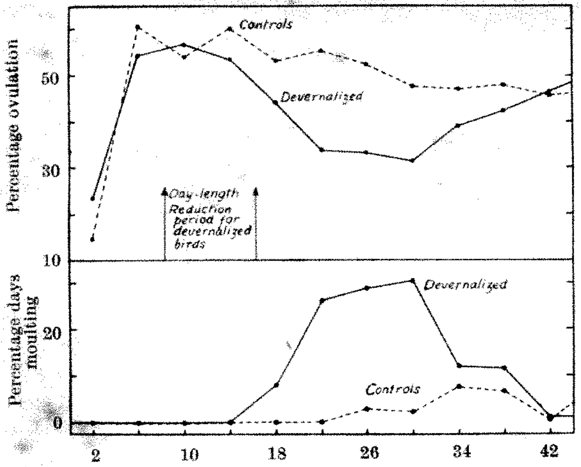

Fig. 1. Ovulation and moulting of survivors of the control group (twenty birds) and the 'devernalized' group (seventeen birds) plotted in periods of 28 days. Moulting days were those on which an appreciable number of feathers were cast, not days on which feathers were growing

batteries from this age, but previously had been in a pen. About two months after the birds had come into lay the day-length of the first group was gradually reduced to 12 hr. over a period of eight weeks and then maintained at this level. This procedure is hereafter called 'devernalization'. In this way the seasonal reduction in day-length in late summer and early autumn was simulated in an exaggerated way. Because the pullets had been in lay for some time before 'devernalization', they represented early hatched birds, which a farmer might expect to moult in the autumn. The day-length for the second group was maintained throughout at 12 hr., an absolute day-length at which good production is normally maintained.

Fig. 1 shows that the production of the 'devernalized' group fell very considerably after the day-length was reduced; it did not recover for some months, and was accompanied by moulting as in farming practice. Its cause cannot be a low absolute day-length, because the 'devernalized' group at no time had a shorter day than the controls. It is unlikely that there was a subclinical infection in the 'devernalized' group, because a fortnight after the end of the treatment the birds of the two groups were mixed. It seems, therefore, that a downward change in day-length can reduce egg production and cause moulting.

From the age of eight weeks up to the end of 'devernalization', the birds had been kept in an environmental temperature of 64° F. A fortnight later, half of each group were exposed to an artificial thermal autumn and winter lasting five months. The temperature during the coldest three weeks averaged 36° F. In agreement with most earlier work on housed birds, discussed by me[4], this had no appreciable effect on production.

A second 'devernalization', after the birds had been in lay for about a year, was successful. Production nearly ceased and moulting was heavy. Controls maintained a reasonable rate of lay.

It is thought that if late summer and autumn 'devernalization' is prevented, and the birds are kept on the intensive system, hatching in Britain could be profitably carried out at any time of the year, so that the supply and price of eggs could be fairly steady, as indeed they are already in the lower latitude of the United States. My experiments are purely fundamental and do not, therefore, indicate the most economic method of controlling 'devernalization'. However, field trials carried out by Temperton[5] suggest that the practical methods of control may be simpler than those used here.

Recent experiments at this Centre[6] show that a short absolute day-length can inhibit production as well as a reduction in day-length; however, when autumn and winter lighting are used, the absolute day-length is never short enough to reduce production in practice.

Eophila oculata at Verulamium: a Roman Earthworm Population?

DURING the excavation of Roman remains lying beneath a car park near the Verulamium Museum, St. Albans, in the summer of 1955 some eighteen living earthworms were found among layers of blackened organic material between eight and fifteen feet below ground-level.

The worms were identified as *Eophila oculata* (Hoff.), a species fairly widely distributed in Britain and Europe. (The specimens were kindly examined by Dr. A. J. Cain, who wrote: "I think there is no real doubt that the worms are *Eophila oculata* (Hoffmeister 1845). Only one or two have traces of the clitellum and tubercula pubertatis, and the latter are slightly atypical in extending over segments 28–30 instead of 29–30 as usually described. Unfortunately none of the apparently most mature show even traces of the spermathecae and seminal vesicles on dissection, so the diagnosis cannot be confirmed. In the extent of the clitellum and the presence of a genital cushion on 11, and one or two other features they agree well with *oculata*.") This worm does not occur in agricultural soils but inhabits aquatic or semi-aquatic places such as the mud at the bottom of ponds, rivers and ditches and the wet soil of their banks. It has been found in wells[1], in clayey soil under rotting sedge at Wicken Fen[2], and among material dredged from the bottom of Lough Mask, Eire, at a depth of between 100 and 150 ft.[3].

The present record is unusually interesting as the worms were found in the remains of a ditch which was filled in during the first century A.D., and then sealed over by the floors of successive buildings erected between the first and fourth centuries A.D. The varying floor surfaces included tile, gravel, mortar and beaten earth, and were in a fair state of preservation. They formed a compact layer from eight to fifteen feet thick which clearly had not been disturbed since Roman times.

The ditch represented the first disturbance of the site by man and may have been a stage in the construction of a defensive ditch which was not completed. It contained, in its lower part, a water-logged black material, and in its upper part, where the worms were found, soil mixed with separate layers of partially decomposed, blackened vegetation among which brushwood, holly leaves, bracken, grass and various types of seeds were recognizable. Domestic refuse including oyster shells, pottery and scraps of leather; many identifiable fly puparia and other insect parts were also found.

Excavation began in April, but had only reached a depth of 2 ft. by July. The rate of working then increased and the ditch was entered by the end of the month. The first worms were found shortly afterwards. They were in well-developed burrows and evidently had not been introduced during the digging. The nearest likely source of this species of worm is the River Ver, 250 yards away; but as the excavation was carried out during a period of drought (total rainfall July and August, 1·06 in.) it is unlikely that they invaded the exposed ditch across the dry partly built-up area in between. No worms or burrows were found between the ditch and the lowest Roman floor and it is also unlikely that the worms would have penetrated the compacted layers, 8–15 ft. thick, above it. They might, however, have migrated along the ditch horizontally if it connected with the river. The full extent of the ditch is not known, but it almost certainly does not connect with the river as the exposed portion curves away from it and lies ten feet above it.

There remains the possibility that the worms entered the ditch in Roman times before it was filled in, and have continued to breed there ever since. This explanation is supported by the presence in the ditch of seeds of *Carex* spp., typically plants of marshy situations, which suggests that the site provided a suitable habitat for *E. oculata* during the Roman period.

Worms and burrows occurred both among the partly decomposed vegetation and in the surrounding clay. Deposits of 'vivianite' (hydrated ferrous phosphate), a substance laid down under reducing conditions, were found among the organic materials, and this, together with the well-preserved state of the vegetation itself, suggests locally anaerobic conditions. The surrounding soil may, however, have been slightly better aerated and, if so, worms in the vegetation could perhaps have obtained some air from this source through their burrows.

A number of other sites from which *E. oculata* has been recorded, for example, the black mud beneath the River Thames and the bottom of Lough Mask, similarly suggest conditions of poor aeration, and the ability of the species to exploit these habitats implies a capacity for absorbing oxygen at very low tensions.

This may be facilitated partly by its relatively large surface/volume ratio—although up to 75 mm. long, it is only 1–2 mm. in diameter. Only two other species in the British Lumbricidae, *Bimastus icenorum* (Pickford)[2] and *Allolobophora minima* Muldal[4], are similarly proportioned (diameters about 1 mm. and 1–1·5 mm. respectively) and both appear to have been found in the same type of habitat as *E. oculata*. *B. icenorum* and *E. oculata* were both collected by Pickford from "clayey soil under rotting sedge" at Wicken, and a specimen of *A. minima* was found by Muldal among preserved *E. oculata* collected by Friend from the Thames and Nottinghamshire. *B. icenorum* has been recorded only once but both *A. minima* and *E. oculata* have been taken from normally aerated sites. All three species seem to have in common at least some habitats and a body form providing an exceptionally high proportion of respiratory surface. It is tempting to speculate whether they may not also share an ability to live in habitats closed to other Lumbricidae under conditions of very restricted oxygen supply.

We are indebted to Mr. John Lunn, director of the excavation and of the Verulamium Museum, for directing our attention to this problem and for supplying us with archæological details of the site, and to Dr. A. J. Cain for identifying the worms and for his comments on the manuscript.

An Arctic Lichen, *Siphula ceratites*, in Scotland

I DISCOVERED a large colony of the arctic lichen *Siphula ceratites* (Wg.) Fr. in April 1955 on the Coulin Forest of Wester Ross (lat. 57° 32′ N., long. 5° 22′ W.). The species is circumpolar, markedly disjunct and predominantly coastal in its distribution[1]. It has been recorded from western and northern Norway, Swedish and Finnish Lappmark, the Petsamo area, Novaya Zemlaya, Siberia, Japan, the Aleutian Islands, the Bering Strait region and the Himalaya but not hitherto from the British Isles.

The altitudinal range of these stations is from near sea-level in south-west Norway to 15,000 ft. (4,570 m.) in the Himalaya, the usual habitat being open plant communities of wet, stony or peaty ground. In Ross-shire the lichen is abundant over some 200 acres (80 hectares) of this type of terrain at an altitude of 1,500–1,800 ft. (458–549 m.) O.D. and is apparently extending its range (Fig. 1).

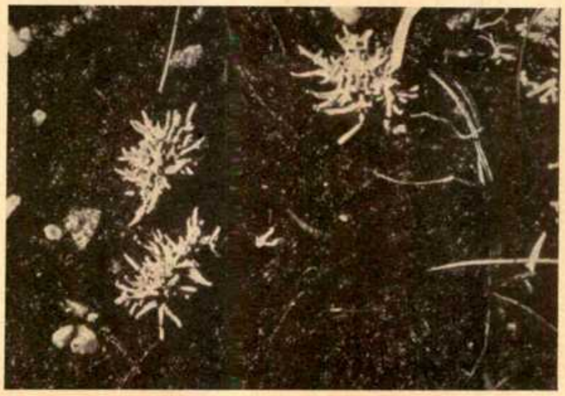

Fig. 1. *Siphula ceratites* on bare peat at 1,800 ft. O.D., Ross-shire, Scotland

Voucher specimens have been deposited in the herbaria of the Royal Botanic Garden, Edinburgh, and the Nature Conservancy, Edinburgh.

I am indebted to Dr. E. Dahl, of Vollebekk, Norway, for identifying the Scottish material.

A detailed account of the Ross-shire locality of *S. ceratites* will be published elsewhere.

Effect of Environment upon the Growth and Development of Raspberry Canes

THE red raspberry (*Rubus idaeus* L.) has a perennial root system; but the shoots ('canes') are normally biennial, elongating in the first season and fruiting and dying in the second. Replacement canes may arise directly from roots, as root suckers, or from dormant buds at about ground-level on fruiting canes. This sequence of growth and development appears to be largely governed by, and in response to, various environmental factors, primarily those of light and temperature. The effects of these factors are being studied by growing plants under controlled conditions in which length of day, light-intensity and temperature can be varied independently.

Fluorescent lighting has been used, giving about 450 ft.-candles at the plant apices. Plants have been grown in three different constant temperatures, at each of which batches of plants were exposed to 9-hr. and 14-hr. day-lengths respectively. As a result of this work, some of the main effects of environment can now be discerned.

It is convenient to define three major phases of growth and development, namely: (1) the initiation of buds upon raspberry roots and their subsequent elongation to the soil surface; (2) the growth of the vegetative shoot in its first year; and (3) the production of flowers, mainly on lateral shoots, followed by fruit development and death of the cane, in the second year. Phase 1 has been discussed elsewhere[1], and is still under investigation. Phases 2 and 3 are discussed below.

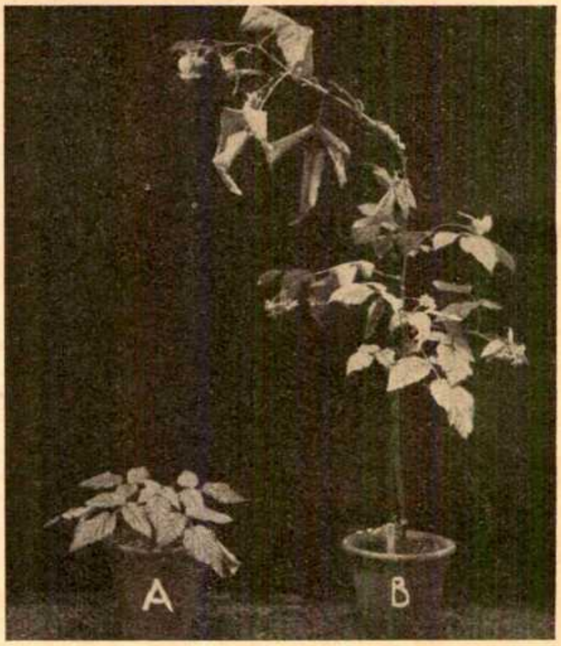

Fig. 2. Plants *A* and *B* were the same age when photographed on December 10, 1955. Plant *A* was grown at 50° F. in a length of day of 9 hr. Plant *B* was grown for 12 weeks at 60° F., 14 hr. length of day, then 'cool-treated' for six weeks at 50° F., 9 hr. length of day, then cold-treated for six weeks at 36° F., 0 light, and thereafter returned to a warm glasshouse where it formed tip and lateral fruit

In phase 2, two distinct forms of growth have been produced, some shoots elongating rapidly whereas others elongated very little, producing compact rosettes of leaves. At 70° F., with a length of day of either 14 or 9 hr., all shoots grew quickly, showing no tendency to form rosettes. In marked contrast, at 50° F. rosettes were formed in both day-lengths. At an intermediate temperature of 60° F., shoots with a 14-hr. length of day elongated, slowly at first but ultimately at a greater rate than those in a comparable length of day at 70° F., whereas plants grown at 60° F. with a 9-hr. length of day formed large rosettes near soil-level and did not elongate. These habits of growth are illustrated in Fig. 1.

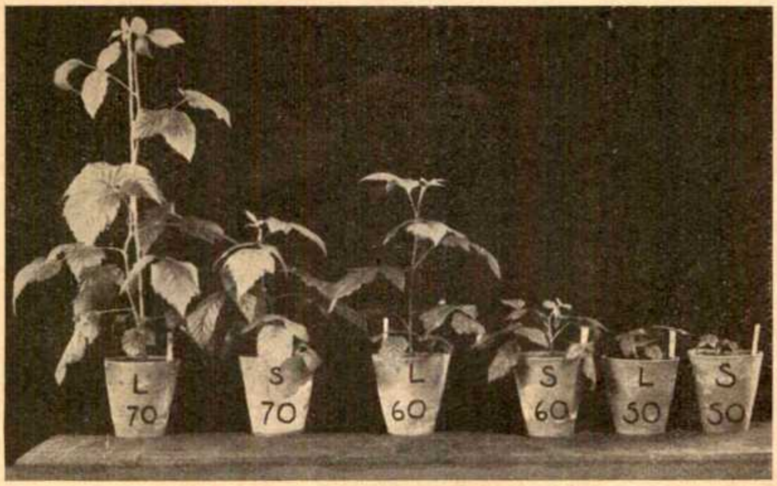

Fig. 1. Raspberry plants propagated from root cuttings on November 3, 1954, and photographed on March 1, 1955, after growing in six different environments. *L*, length of day of 14 hr.; *S*, 9 hr.; 70, 60 and 50 are constant temperatures in degrees Fahrenheit

It is of particular interest to note the interaction of temperature and photoperiod. At temperatures of about 60° F., elongation appears to depend upon length of day, whereas at lower temperatures rosettes form, and at higher temperatures shoots elongate, irrespective of the length of day.

Response to the environment is not confined to the young shoot or to growth near ground-level. Strongly elongating shoots, up to five feet or more in length, can be induced to form terminal rosettes of leaves either by giving lower temperatures or shorter days. Conversely, a shoot which has formed a terminal rosette can be induced to elongate again if the length of day is increased or the temperature raised.

When grown at sufficiently high temperatures, in heated glasshouses, raspberry canes have continued to elongate for considerable periods and have attained lengths of more than twelve feet without showing any tendency to go dormant, even in low light-intensities and short days of winter.

Phase 3, flowering and fruiting, can be initiated by exposing plants with elongated canes to a period of low temperatures, between 35° F. and 40° F. for periods up to six weeks. With the varieties Lloyd George and Malling Promise, a short period of a few days at low temperatures resulted in the production of a terminal flowering shoot when the plants were returned to higher temperatures. On the other hand, exposure of equally mature canes to longer periods of low temperature resulted in an increasing proportion of the lateral buds growing out to form mixed fruiting laterals (Fig. 2).

During exposure to low temperatures, canes become dormant and the leaves fall. It is not necessary for plants to be exposed to light during this period. When plants have been returned to the conditions of higher temperatures and light of a glasshouse and laterals have begun to develop, length of day seems to have little influence upon further growth of the laterals and flower and fruit formation.

Exposure of the canes to a period of short days and a temperature of 50° F. before giving them the low temperature of 35–40° F. materially influences the effectiveness of the latter treatment.

The age of the cane, as measured by the number of nodes produced, is also an important factor in flower initiation and development. Young canes with fewer than twelve nodes have so far failed to flower in response to any treatment applied.

The work is continuing and will be described in greater detail elsewhere. Permission to use the photograph in Fig. 1 is gratefully acknowledged to Mr. B. Cox of *The Grower*.

Seasonal Sweating

PALMAR sweating increases in young women when their environmental temperature is artificially raised[1], and it is therefore reasonable to suppose that palmar sweating is related directly to environmental temperature and will vary with it in the different seasons of the year. As a preliminary test of the supposition, five women aged 18–20 years were observed for a month in summer and a month in winter, menstrual months being chosen in preference to calendar months to eliminate luteal effects[2]. The menstrual cycles chosen to represent summer and winter were those which began in August and in February.

Sweating was assessed by the number of active glands in an area of skin 4 mm. square immediately distal to the central whorl of the right middle finger[3]. Three hundred counts were made under basal conditions, 156 in summer and 144 in winter, and the mean counts were found to be 60·0 and 100·1 respectively, the standard error being 7·4. Therefore basal palmar sweating in the five women investigated was suppressed in summer to a degree which, from the statistical point of view, is abundantly significant[4]. Body temperatures of the women were taken at the same time and the average found to be 0·3 deg. F. higher in the summer month than in the winter month.

The suppression of basal palmar sweating in summer cannot be a thermoregulatory phenomenon, particularly in view of the raised body temperature in the women under observation, nor, unless winter is regarded as a time of shock, can it be explained as a recovery phase from shock. But subcutaneous injection of 25 mgm. of adrenocorticotrophic hormone suppresses palmar sweating (unpublished results), and there is considerable indirect evidence that an increase in suprarenal cortical activity acts in the same way[5]. Therefore, if suprarenal cortical activity is increased in summer, the paradoxical suppression of basal palmar sweating would be explained. Increased suprarenal cortical activity would also explain various other summer phenomena of unknown etiology—for example, neutrophilia[6], increased resistance to bacterial infection[7] and low death-rate from respiratory infection[8].

Reaction between Formic Acid and Nitrogen Dioxide

DURING a study of a series of compounds of general formula $R'R''CO$ with nitrogen dioxide, we have investigated the reaction of formic acid with nitrogen dioxide. The reaction was carried out using a cylindrical 'Pyrex' glass reaction vessel (volume ~ 158 c.c., surface area ~ 167 cm.^{2}) and was followed by measurement of the increase of total pressure, and photometric estimation of nitrogen dioxide. Analyses of the final products were carried out as required using standard techniques described previously[1]. Initial pressures of 0–100 mm. each reactant were used, most of the experiments being carried out at 220° C. Under these conditions, nitrogen dioxide is very little associated[2] or dissociated[3], and formic acid is almost completely present as the monomer[4].

The reaction proceeds quite readily at 220° C. according to the overall equation:

$$HCO_2H + NO_3 = H_2O + CO_2 + NO$$

In agreement with this equation, the increase of pressure at any given time was found to be equal to the pressure of nitrogen dioxide which had been used. The pressure increase – time curves are, however, unexpectedly linear for a considerable portion of reaction at 220° C., although the slope of the linear portion is proportional to the first power of the initial pressure of each reactant. It appears, therefore, that the initial overall second-order rate is in some way maintained, indicating the possibility of autocatalysis.

This is supported by the fact that added nitric oxide was found to increase the rate of reaction, whereas additions of water and of nitrogen had very little effect.

For a given mixture of formic acid and nitrogen dioxide, it was observed that the rate was increased in proportion to the amount of nitric oxide added (see Table 1).

Table 1

$p_i NO_2$ = 24·0 mm. $p_i HCO_2H$ = 30·0 mm.	T = 220·0° C.
pNO added (mm.)	Initial rate × 10^3 (mm./sec)
0·0	0·92
9·2	1·30
21·1	1·98
39·9	2·34
56·5	2 63
72·3	2·99
151·6	5 10

Experiments were then carried out using different mixtures of formic acid, nitrogen dioxide and nitric oxide. These show that the rate of reaction can be expressed by an equation of the form

$$\frac{d(\Delta P)}{dt} = \frac{-d(NO_2)}{dt} = k_1(HCO_2H)(NO_2)\left\{1 + \frac{k_2(NO)}{k_1}\right\}$$

$$\text{At } 220^\circ\text{ C.,}\ \left.\begin{aligned} k_1 &= 3{\cdot}78 \times 10^{-1}\ \text{l. mole}^{-1}\ \text{sec.}^{-1} \\ k_2 &= 3{\cdot}56 \times 10^{+2}\ \text{l.}^2\ \text{mole}^{-2}\ \text{sec.}^{-1} \end{aligned}\right\}\ \text{average values}$$

The reaction was found to be largely influenced by surface. Experiments using a reaction vessel packed with 'Pyrex' glass tubing which increased the surface/volume ratio by a factor of nine produced approximately a nine-fold increase in rate. The velocity constants quoted above should therefore be related to the dimensions of the reaction vessel used.

Further experiments on this reaction are being carried out and it is hoped to publish full details at a later date. The present observations, however, are in agreement with those concerning the reactions of a number of compounds of general formula $R'R''$CO with nitrogen dioxide (Table 2). It appears that the presence of an easily removable hydrogen atom (that is, an aldehyde group) facilitates reaction. This does not necessarily imply that hydrogen abstraction occurs and is equally consistent with an initial addition reaction as proposed for the formaldehyde/nitrogen dioxide reaction by Pollard and Wyatt[1] and more recently extended by Walsh[5].

Table 2

R'	R''	Reaction of $R'R''$CO with NO_2		Ref
		Temperature range (° C.)	Comments	
H	H	118–184	Homogeneous reaction < 160° C. E = 15 kc./m. > 160° C. E = 19 kc./m.	1
CH_3	H	110–180	Homogeneous reaction E = 15·2 kc /m.	6
OH	H	210–260	Heterogeneous reaction	This work
CH_3O	H	250	Slow reaction probably heterogeneous	
CCl_3	H	146	Slow reaction	6
CH_3	OH	150	No detectable reaction	6
CH_3	CH_3	146	Very slow reaction	6

Formic acid and methyl formate (which has been briefly studied at 250° C.) differ from the other compounds of this series in the heterogeneity of their reactions with nitrogen dioxide.

The effect of nitric oxide upon the former may well be due to the occurrence of a surface reaction (a possibility is the formation of dinitrogen trioxide), and this would explain why nitric oxide does not increase the rate of, for example, the acetaldehyde/nitrogen dioxide reaction.

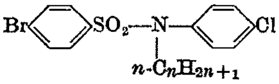
Substituted Benzenesulphonanilides as Synergists for DDT

A SERIES of 4-bromobenzenesulphon-4′-chloroanilides of type (I) have been synthesized and tested for synergistic activity with DDT against DDT-resistant house-flies.



n = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12

(I)

The test subjects were of a strain '*M*' of *Musca domestica vicina* Macq. moderately resistant to DDT, which had originated in 1949 from flies caught in Rosh-Pina, Israel. The potential synergists were tested together with DDT by topical application of benzene solutions (0·175 µl. solution per fly, containing 0·175 µgm. of DDT and 0·0175 µgm. of a potential synergist). Mortality was observed 6 hr. after application. When DDT by itself was applied topically in benzene solution, *LD*25 was 1·3 µgm., *LD*50 was 5·7 µgm. and *LD*75 was 20·1 µgm. per fly. The activity of the potential synergists in the form of residual deposits was tested by a modification of the method of Mer and Davidovici[1]. House-flies were individually induced to walk for 90 sec. first over a glass surface carrying a residual deposit of 10 µgm./cm.^{2} of a potential synergist, and afterwards for the same time over a similar surface carrying 100 µgm./cm.^{2} of p,p'-DDT, at 24–25° C. Knockdown was recorded 3 hr. after contact.

Figs. 1 and 2 represent the biological proportional response (plotted on a probit scale) as a function of increasing alkyl chain-length n of the synergists. The observed proportional response values were analysed statistically by the method for comparing individual means proposed by Tukey[2] and elaborated by Hald[3]. This method permits the classification of means into groups which can be considered as belonging to a statistically homogeneous population of such means. The proportional mortality values observed after topical application formed two

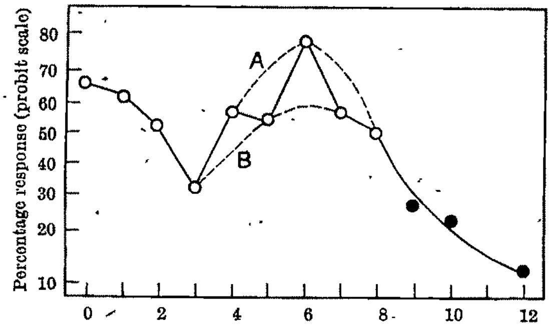


Fig. 1. Percentage knock-down of DDT-resistant house-flies 3 hr. after consecutive contacts for 90 sec. with residual deposits of 10 µgm./cm.^{2} of N-*n*-alkyl-4-bromobenzenesulphon-4′-chloroanilide synergists and of 100 µgm./cm.^{3} of DDT, respectively. Filled circles denote a response not significantly higher than that to DDT alone. *A*, even homologues; *B*, odd homologues

statistically homogeneous groups of responses which were significantly higher than the response to DDT by itself. These groups were {1, 2} and {0, 3, 4, 5, 6, 7, 8}, the figures in brackets denoting *n* of the compounds (I) in each group. The group of compounds {9, 10, 12} showed no significant synergistic activity. The proportional knock-down values observed after short-duration contact of flies with residual deposits[3] formed three statistically homogeneous groups: {6}; {0, 1, 2, 4, 5, 7, 8}; and {3}. The remaining group {9, 10, 12} showed no significant increase of response in comparison to that caused by DDT alone (13 per cent knock-down). The level of significance for all statistical tests was $P = 0{\cdot}05$. The compounds of type (I) showed no insecticidal activity when tested by themselves by the short-contact method.

The curves of biological response versus alkyl length (Figs. 1 and 2) may be divided into three parts: low range ($n = 0$ to $n = 3$), medium range ($n = 4$ to $n = 8$), and high range ($n = 9$ to $n = 12$). In the low range, the response to contact and to topical application showed similarity. In the medium range the response to topical application showed little change, while two additional factors appeared in the contact response curve, namely, maximum response near C_6, and differentiation of the series into separate sub-series of homologues with even-numbered and of those with odd-numbered alkyl radicals. For each sub-series a separate smooth curve for response vs. alkyl chain-length resulted, and therefore the homologous series as a whole formed a zig-zag line. The curves for both sub-series were of similar ω-shape the even homologues caused a higher response than the odd ones. In the high range ($n = 9$ to $n = 12$) the synergistic activity disappeared.

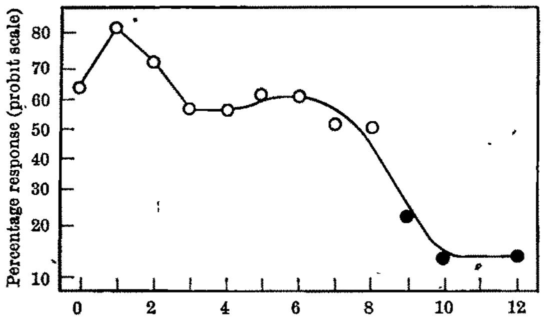

Fig. 2. Percentage mortality of DDT-resistant house-flies 6 hr. after topical application of 0·175 µgm. of DDT + 0·0175 µgm. of N-*n*-alkyl-4-bromobenzenesulphon-4′-chloroanilide synergists in benzene. Filled circles denote a response not significantly higher than that to DDT alone

For comparison several synergists which have been previously reported active when tested by other methods have been subjected to the short-duration contact test described above. 1,1-*Bis*-(*p*-chlorophenyl) ethane, which was reported by March and co-workers[4] to be highly active by topical application, showed no synergistic activity by short contact (10 per cent knock-down), while 4-chlorobenzenesulphon-4′-chloroanilide, reported by Speroni[5] to be active by 24-hr. contact, was also active by short contact (56 per cent knock-down). The N-*iso*-amyl isomer of the compound (I, $n = 5$) was inactive by topical application as well as by the short-contact test.

A detailed discussion of the observed correlation will be published elsewhere. Other synergists are being investigated.

Thanks are due to Prof. E. D. Bergmann for valuable discussions. Statistical analysis was carried out by S. Zacks.

Kelvin on the Origin of the Earth

A GEOPHYSICAL discussion on the origin of the Earth reported in *Nature* some time ago[1] included an account of his so-called 'pore theory' by Mr. T. Gold. He suggested that an Earth which formed by the agglomeration of solid dust particles would, due to the heating effects of compression and radioactivity, contain a certain fraction of liquid mixed with the solid. A structure of pores or veins of liquid might be set up, and the percolation downwards and upwards of dense and light liquids could account for the formation of the Earth's core and of its atmosphere and oceans, respectively, while various hydraulic actions could explain earthquakes, vulcanism and structural features such as great upheavals.

While looking up a reference in Lord Kelvin's collected works recently, I was interested to observe that nearly one hundred years ago he had considered a similar mechanism in his article "On the Secular Cooling of the Earth"[2]. He suggested that in the process of cooling of a completely or partially liquid globe, portions of solid crust would continually sink until a "close ribbed solid skeleton or frame" had been built up from the bottom of the liquid layer. I quote what follows:

"In the honey-combed solid and liquid mass thus formed, there must be a continual tendency for the liquid, in consequence of its less specific gravity, to work its way up; whether by masses of solid falling from the roofs of vesicles or tunnels, and causing earthquake shocks, or by the roof breaking quite through when very thin, so as to cause two such hollows to unite, or the liquid of any of them to flow out freely over the outer surface of the Earth; or by gradual subsidence of the solid, owing to the thermodynamic melting which portions of it, under intense stress, must experience, according to views recently published by my brother, Professor James Thomson. The results which must follow from this tendency seem sufficiently great and various to account for all that we see at present, and all that we learn from geological investigation, of earthquakes, of upheavals and subsidences of solid, and of eruptions of melted rock."

Lord Kelvin thus seems to have anticipated some of Mr. Gold's ideas, although they, of course, differ as to the origin of the supposed porous structure, and Mr. Gold has given more attention to what such a hypothesis might entail.

IT is interesting to know that Lord Kelvin held similar views though for different reasons, and especially that he considers also that a porous structure of the Earth would account for a variety of the phenomena that have occurred on the surface. The views of Chamberlain and Moulton, following their planetesimal hypothesis of the formation of the Earth, are perhaps even more similar to those which I have expressed. This set of ideas seems to me to have been much neglected despite the fact that it is in good accord with modern physical and geophysical knowledge.

Influence of Expanding Space on the Gravitational Fields surrounding Individual Stars

Einstein and Strauss[1] have found solutions of the gravitational field equations of general relativity

$$G_{\mu\nu} = -k\rho v_\mu v_\nu \qquad (1)$$

$\mu, \nu = 1, 2, 3, 4$, such that (i) outside a spherical boundary $r = R_1$ (R_1 is a constant), the metric is homogeneous and isotropic, the co-ordinates are co-moving ($v_r = 0$, $r = 1, 2, 3$) and the density ρ does not vanish; (ii) inside $r = R_1$, the metric is spherically symmetric and $\rho = 0$, except for a possible singularity at or near the space-origin.

It is shown that the field inside $r = R_1$ is equivalent to the Schwarzschild field. Einstein and Strauss therefore conclude that "the expansion of space has no influence on the structure of the field surrounding an individual star".

However, Pirani[2] has shown that this negative result is obtained only because of the omission of the cosmological term $\lambda g_{\mu\nu}$ from the left-hand side of equation (1). By introducing this term, he has found that expanding space does influence the gravitational field.

Generally, stars are radiating energy. Hence we considered the Einstein–Strauss problem when the singularity at or near the origin is a source of radiation. In that case the space surrounding this singularity is not empty but is traversed by radially flowing radiation for which

$$\begin{aligned} G_{\mu\nu} &= -k\sigma\omega_\mu\omega_\nu \\ \omega_\mu\omega^\mu &= 0 \\ (\omega^\mu)_\nu\omega^\nu &= 0 \end{aligned}$$

σ being the density of flowing radiation[3]. The differential equations for this field can be solved in a manner similar to that employed by Einstein and Strauss in the investigation of the field (ii) mentioned above; but a fundamental difference arises when we try to fit this radiation-field with the pressure-free cosmic field given in (i) above, over a boundary $r = R_1$. The boundary $r = R_1$ now becomes non-static and moves with the velocity of light. The necessary jump conditions to be satisfied at such boundaries are derived by O'Brien and Synge[4]. According to them, if co-ordinates are so chosen that the boundary $r - R_1(t) = 0$ becomes $x^4 = 0$ in the new co-ordinates, then one of the essential conditions is the continuity of $T_k{}^4$ at this boundary ($k = 1, 2, 3, 4$). We have found that if the Einstein–Strauss singularity radiates energy, the components $T_k{}^4$ (evaluated in the appropriate co-ordinate system) are all zero for $r < R_1(t)$, but two of them are definitely non-zero in the cosmic field $r > R_1(t)$. It is therefore not possible to make $T_k{}^4$ continuous across the boundary $r = R_1(t)$. Hence we conclude that if the Einstein–Strauss singularity radiates energy, the field (ii) for $r < R_1(t)$ can never be fitted at the boundary $r = R_1(t)$ to a pressure-free cosmic field (i) with spatially homogeneous non-zero density of matter, irrespective of the vanishing or otherwise of the cosmic 'constant' λ. The jump conditions of O'Brien and Synge allow the fitting of such radiation fields with flat space-time alone, at great distances.

According to Einstein and Strauss, the expanding space of cosmology can be fitted on to a static Schwarzschild field without influencing it. But we have now seen that as soon as the Schwarzschild's singularity begins to radiate energy, the Einstein–Strauss process of fitting the two fields breaks down. We therefore cannot locate a definite (static or non-static) boundary $r = R_1$, such that on one side of it we have expanding space and on the other side a field quite uninfluenced by the surrounding expanding space.

Since all stars are radiating energy, a simple appeal to the jump conditions of O'Brien and Synge leads one to the conclusion that the expansion of space does influence the structure of the fields surrounding individual stars. The exact nature and extent of this influence are now being investigated.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, April 30

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Efficient Use of Technical Personnel", opened by Sir George H. Nelson, Bart.

Tuesday, May 1

Faraday Society (in the Physical Chemistry Lecture Theatre, Imperial College, London, S.W.7), at 5.15 p.m.—Prof. J. J. Hermans (Leyden): "The Physical Properties of Polymer Solutions"* (Bourke Lecture).

Tuesday, May 1—Wednesday, May 2

Institute of Fuel (at Church House, Westminster, London, S.W.1), at 10 a.m.—Opening Conference of a Special Study of "Domestic Heating in the United Kingdom—Present and Future".*

Wednesday, May 2

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Miss Violet R. Cane: "Some Statistical Problems in Experimental Psychology".

University of London (at Senate House, London, W.C.1), at 5.30 p.m.—Prof. E. C. Wassink (Netherlands): "Morphogenetic Effects of Restricted Spectral Regions of Light in Plants".* (Further Lecture on May 3.)

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 7 p.m.—Dr. J. H. Hamence: "The Composition of Some Deposits and Muds in Estuaries, Rivers and Lakes".

Wednesday, May 2—Friday, May 4

Institution of Electrical Engineers (at Savoy Place, London, W.C.2)—Convention on "Electrical Equipment of Aircraft".

Thursday, May 3

Faraday Society (in the Large Lecture Theatre, Chemistry Department, The University, Birmingham), at 4.30 p.m.—Prof. J. J. Hermans (Leyden): "Polyelectrolytes"* (Bourke Lecture).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. D. Lowde: "Spin Fluctuation Scattering of Neutrons and the Ferromagnetic State in Iron"; Mr. R. J. Eden: "The Brueckner Theory of Nuclear Structure".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. Rzoska: "Journeying Down the Nile".*

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. N. L. Edson (University of Otago): "The Intermediate Metabolism of Carbohydrate in the Mycobacteria".*

Institute of Refrigeration (joint meeting with the Low Temperature Group of the Physical Society, at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. D. Smith: "The Use of Radioactive Techniques in Refrigeration Engineering".

Institution of Chemical Engineers (at the Royal Institution, Albemarle Street, London, W.1), at 5.30 p.m.—Mr. H. G. Davey: "Some Problems in the Maintenance of Nuclear Reactors".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, May 4

Faraday Society (in the Nicholson Lecture Theatre, Department of Organic Chemistry, The University, Liverpool), at 5 p.m.—Prof. J. J. Hermans (Leyden): "Light Scattering by Solutions"* (Bourke Lecture).

Institution of Mechanical Engineers, Hydraulics Group (at Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. H. P. Hutton: "Three Dimensional Motion in Axial Flow Impellers"; Dr. E. A. Spencer: "The Performance of an Axial Flow Pump".

Institute of Physics, Non-Destructive Testing Group (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Symposium on "Principles of Penetrant Methods".

Royal Institution (at 21 Albemarle Street, London, W 1), at [illegible] p.m.—Prof. J. Z. Young, F.R.S.: "The Discrimination of Shapes by Animals and Machines".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Chemist (with an honours degree in chemistry or A.R.I.C., or equivalent qualifications, and at least three years experience in the industrial chemistry field) at the Atomic Weapons Research Establishment, Aldermaston, Berks, for duties which will include the control of water-treatment plants, trade waste treatment and radioactive effluent treatment and disposal systems, special laundry for contaminated protective clothing and the decontamination of plant and equipment—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1104/34 (May 2).

Animal Physiologist (with an appropriate honours degree or equivalent qualification) to undertake experimental work with hill sheep—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh 12 (May 5).

Assistant, Grade B (with an honours degree in botany or zoology and able to teach both subjects to the advanced level of the general certificate of education), to teach Biology in the Natural Science Department—The Principal, Derby and District College of Technology, Normanton Road, Derby (May 5).

Deputy Librarian (Chartered Librarian)—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (May 7).

Lecturer, Grade B (with a good honours degree of a British university, and preferably teaching experience) in Mathematics—Clerk to the Governing Body, Battersea Polytechnic, London, S.W.11 (May 11).

Assistant Experimental Officer (with a degree in botany or an allied biological science) in the Department of Plant Breeding to assist with cytological studies of horticultural crops—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (May 12).

Head (with high academic qualifications in engineering with industrial, and, preferably, research experience, and capable of directing the teaching and administration of a large and expanding department) of the Department of Civil, Mechanical and Marine Engineering, City College of Technology, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool (May 12).

Scientific Officer or Senior Scientific Officer (with a first- or second-class honours degree or equivalent in statistics or mathematics, and experience in design and analysis of scientific investigations, and preferably with some knowledge of forestry or other biological subject) at the Forestry Commission Research Station, near Farnham, Surrey, for statistical work—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.127/6A (May 12).

Fellow in the Department of Particle Physics to assist in the completion, operation and experimental use of a 10-BeV. proton synchrotron—The Registrar, Australian National University, Box 4, G.P.O., Canberra, A.C.T., Australia (May 14).

Assistant Lecturer in Statistics—The Registrar, The University, Hull (May 15).

Lecturer in Zoology—The Secretary, The University, 38 North Bailey, Durham (May 15).

Lecturer (preferably with a qualification in physical organic chemistry, and an interest in infra-red spectroscopy) in Organic Chemistry, at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 15).

Field Pedologist (with a university honours degree in science or agricultural science, preferably with postgraduate research experience), at the headquarters of the Division of Soils, Commonwealth Scientific and Industrial Research Organization, Adelaide, to undertake surveys and field studies of Australian soils—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 270/129 (May 19).

Lecturer in Technical Mathematics—The Assistant Secretary, The University, Edinburgh (May 19).

Lecturer (preferably with a veterinary qualification) in the Department of Veterinary Physiology—The Assistant Secretary, The University, Edinburgh (May 19).

Lecturer (preferably with some knowledge of microwave techniques) in Electrical Engineering—The Registrar, The University, Sheffield (May 19).

Research Biochemist in the Regional Pastoral Laboratories, Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, Armidale, N.S.W., Australia, to conduct a series of investigations into biochemical aspects of the soil–plant–animal relationship with particular reference to sulphur metabolism, as part of a general programme concerned with the utilization and management of native and sown pastures—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 208/83 (May 19).

Electrical Engineer or Physicist (with a first- or second-class honours degree or equivalent in electrical engineering or physics, and preferably with a good physics and electronics background) at an Air Ministry Experimental Establishment in Norfolk, for the development of airborne radio receiving and transmitting equipments and their associated aerial systems operating mainly on centimetric wave-lengths—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.134/6A (May 21).

Research Fellow in the Department of Mathematical Physics—The Registrar, The University, Birmingham 15 (May 22).

Lecturer (Grade II) or Assistant Lecturer (Grade III) in Botany—The Registrar, The University, Birmingham 15 (May 26).

Research Fellows (3) (with a good honours degree in physics, mechanical or chemical engineering) in the Department of Textile Industries—The Registrar, The University, Leeds 2 (May 28).

Lecturer (with special experience in virus diseases) in Microbiology—The Secretary, Queen's University, Belfast (May 30).

Assistant Lecturer in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (May 31).

Astronomer Royal for Scotland and Professor of Astronomy in the University of Edinburgh—The Private Secretary to the Secretary of State, St. Andrew's House, Edinburgh 1 (May 31).

Botanist (Assistant Experimental Officer grade) for developmental and anatomical studies of fruit—The Secretary, East Malling Research Station, near Maidstone, Kent (May 31).

Lecturer in Industrial Metallurgy—The Registrar, The University, Birmingham (June 1).

Steetley Research Fellow (graduate, or student graduating this year, of any British university), for research in refractories technology—The Registrar, The University, Sheffield (June 12).

Senior Lecturer (specialized in some branch of pure mathematics, applied mathematics, or mathematical statistics) in Mathematics, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 15).

Assistant Chemist (with a degree in chemistry or agricultural chemistry or A.R.I.C.), for analytical work on crops and soils; and a Horticulturalist or Chemist (with a degree in horticulture or chemistry), for glasshouse work on soils and crop nutrition—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 103.

Assistant Conservators of Forests in the Local Civil Service, Gold Coast Government—The Secretary for Recruitment, Gold Coast Office, 13 Belgrave Square, London, S.W.1.

Assistant, Grade A, to teach Pure and Applied Mathematics—The Principal, Technical College, Queen Street South, Huddersfield.

Assistant or Associate Professor in the Department of Physics—J. H. L. Johnstone, Department of Physics, Dalhousie University, Halifax, N.S., Canada.

Biochemist (with a first- or second-class honours degree in biochemistry or equivalent qualification, and postgraduate research experience), to assist in the study of certain physico-chemical properties of mucin—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 56/3.

Chemists, Grade III (with an honours degree in chemistry or chemical engineering, or A.R.I.C. or A.M.I.Chem.E., or equivalent qualifications) with the Ministry of Supply at Chorley, Lancs, to assist in process study, chemical engineering, design and experimental work on new process plant of unusual nature—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.238/6A.

Lecturer in Agriculture, and an Assistant Lecturer in Dairying—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon.

Lecturer or Assistant Professor in the Department of Mathematics, Joint Faculty of Arts and Science at Dalhousie and King's Universities—Dean of Arts and Science, Dalhousie University, Halifax, Nova Scotia.

Lecturer (with good graduate qualifications in physics, with industrial and/or teaching experience, and preferably research experience) in the Department of Physics, City College of Technology, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool 1.

Lecturers (2) (with research interest in applied mathematics or statistics) in Mathematics—The Secretary, Royal Technical College, Glasgow.

Master to teach Physics (including advanced and scholarship levels)—The Headmaster, Bishops Stortford College, Herts.

Physicist (graduate, with a knowledge of mass spectrometry and its associated vacuum techniques, and modern electronic circuitry) in the Biophysics Department of the Postgraduate Medical School (University of London), to continue the development and application of a mass spectrometer for rapid and continuous analyses of gas blends in respiratory research—The Dean, Postgraduate Medical School of London, Ducane Road, London, W.12.

Research Scholars (with graduate or equivalent qualifications) in the Department of Chemistry, Colour Chemistry and Dyeing and/or other Departments—The Principal, Technical College, Queen Street South, Huddersfield.

Scientific Officer (Entomologist) to work on insecticides derived from plants; and Experimental Officers (male or female, with a knowledge of zoology, and preferably chemistry), one for histological and one for ecological work on the action of insecticides—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

PERMUTIT

ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

Permutit Ion Exchange Materials — Made in Britain by British Labour

THE GRIFFIN THERMOSTATIC OVEN

FOR ALL-ROUND THERMAL EFFICIENCY

The Griffin Thermostatic Oven has been designed for use in Chemical, Metallurgical, Bacteriological and Pathological laboratories. It is ideal for all drying and sterilizing work.

Easy to clean and resistant to staining, the exterior has a durable cream finish, the interior being aluminium. The door and casing are heavily lagged and a combined thermometer support and rotatable ventilator is fitted in the roof.

Simple to operate, the base controls comprise an on/off switch, pilot lamp and sensitive slow-motion thermostat. A temperature gradient of ±1° C., over the range from about 5° C. above ambient to 300° C., is constantly maintained. No measurable temperature variations at any one point can be detected.

Low power consumption is achieved by the most careful design and disposition of the heating elements. The chamber space is 26 cm. by 36 cm. diameter £54 0 0

LECTURES AND COURSES

THE WRIGHT-FLEMING INSTITUTE OF MICROBIOLOGY

ST MARY'S HOSPITAL MEDICAL SCHOOL
LONDON, W 2

A Course of six Almroth Wright Lectures has been arranged for the Summer Session, 1956. These Lectures will be given on the following dates in the Lecture Theatre of this Institute at 5 p m Tuesday, May 8, Professor L Pillemer (Western Reserve University, Cleveland, Ohio, U S A), "The Nature of the Properdin System"; Tuesday, May 15, Dr. W E. van Heyningen (Sir William Dunn School of Pathology, University of Oxford), "Recent Trends in Research on Bacterial Toxins"; Tuesday, May 22, Professor F W. Rogers Brambell (Department of Zoology, University College of North Wales, Bangor), "Transmission of Passive Immunity"; Tuesday, May 29, Dr R. E O. Williams (Central Public Health Laboratory, Colindale, N W 9), "The Numbers and Significance of Bacteria in Air", Tuesday, June 5, Professor C. H Stuart-Harris (University Department of Medicine, Sheffield), "Recent Studies in Acute Respiratory Disease"; Tuesday, June 12, Professor R. Hare (Bacteriology Department, St. Thomas's Hospital), "The Transmission of Infections of the Respiratory Tract"

These Lectures are open to all members of the medical profession and to all students in medical schools without fee.

UNIVERSITY OF LONDON

A course of four lectures on (i and ii) "Experiments and Experiences with High Grade Corrugated Reinforcing Steel of the Qualities Kam 60 and kam 95, corresponding to Yield Points 85,000 and 135,000 p s i."; and (iii and iv) "Problems concerning Pile Driving and Foundation on Piles of Timber, Concrete and Steel in Sweden" will be given by Professor H. Granholm (Göteborg) at 5 30 p m. on May 7, 8, 9 and 11, at King's College, Strand, W C.2

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar.

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF ELECTRICAL ENGINEERING AND DEPARTMENT OF EXTRA-MURAL STUDIES
SUMMER SCHOOL ON COMMUNICATION THEORY, MODULATION AND NOISE

The School is intended for engineers in the electrical communications and allied fields who have taken their degrees without much theoretical work in communications or feel the need for a "refresher" course. July 1-13, 1956 At the Department of Electrical Engineering. Tuition £8 Residential accommodation available.

Further Information: Director of Extra-Mural Studies, The University, Edmund Street, Birmingham, 3.

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952

UNIVERSITY OF READING

Applications are invited for a Lectureship in Chemistry. Candidates should possess special qualifications in organic chemistry and should have undertaken independent research in some branch of this subject The appointment, which will date from September 30, 1956, will be in Grade II; salary scale £650 by £50 to £1,050

Further particulars may be obtained from the Registrar, to whom applications should be sent not later than May 25, 1956.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in Chemistry. Candidates should have special qualifications in physical chemistry Salary on a scale £550 to £650 per annum, with membership of F S.S.U. and Children's Allowance Scheme.

Applications should be sent not later than May 28, 1956, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

UNIVERSITY OF GLASGOW

LECTURESHIP AND FELLOWSHIPS IN EXPERIMENTAL PHYSICS OF THE SOLID STATE

Applications are invited for the post of Lecturer. Salary scale: £650 by £50 to £1,350. Initial salary according to experience and qualifications. F.S S U and family allowance benefits The successful applicant will be expected to prosecute experimental research on solid state physics in addition to teaching duties. Applications (five copies), including the names of two referees, should be sent not later than May 31, 1956, to the Secretary of the University Court, The University, Glasgow, W.2, from whom further particulars may be obtained. Applications are also invited for vacant Research Fellowships and Studentships in experimental Solid State Physics Appointment will be for a period of three years at a salary in the range £400 to £800 according to qualifications

Applications for these posts, stating age, qualifications, research experience and names of two referees, should be sent to the Professor of Natural Philosophy, The University, Glasgow, W 2, before May 31, 1956

ROBT T. HUTCHESON,
Secretary of the University Court

UNIVERSITY OF LIVERPOOL

Applications are invited for the following posts in the department of applied mathematics: (i) Assistant Lecturer, at an initial salary of £550 per annum, or in special circumstances, £600 per annum; and (ii) Lecturer, at an initial salary within the range £650 to £850 per annum, according to qualifications and experience

Applications, stating age, academic qualifications and experience, together with the names of two referees, should be received not later than May 23, 1956, by the undersigned, from whom further particulars of the conditions of appointment may be obtained

STANLEY DUMBELL
Registrar.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer in Mathematics. Candidates should have special qualifications in applied mathematics an interest in fluid dynamics will be an advantage. Salary scale £650 to £1,350 per annum with membership of F S S.U. and Children's Allowance Scheme Initial salary according to qualifications and experience.

Applications should be sent not later than May 19, 1956, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained

---

UNITED LEEDS HOSPITALS

GENERAL INFIRMARY AT LEEDS

Applications are invited for the following posts in the new Urological Research Laboratories. Senior Technician I (Biochemistry). Medical Laboratory Technician or Junior Technician, according to qualifications (biochemistry) Salaries according to Whitley Council Scales

Applications, with details of age, qualifications, experience and the names of two referees, to be sent to the Secretary to the Board within two weeks of the appearance of this advertisement.

UNIVERSITY OF SHEFFIELD

Applications are invited for a post of Senior Lecturer or Lecturer in Biochemistry, to begin duties on September 1, 1956, or as soon as possible thereafter. Salary scales: (a) for candidates holding a registered medical qualification, Senior Lecturer £1,750 by £100 to £2,050; Lecturer, £1,000 by £100 to £1,700. (b) For other candidates, Senior Lecturer, £1,400 by £50 to £1,650; Lecturer, £650 by £50 to £1,350. Commencing salary in either grade according to qualifications and experience, with F.S S U. provision and family allowance

Applications (eight copies), should be sent to the Registrar, from whom further particulars may be obtained by May 26, 1956.

THERE WILL BE A VACANCY IN THE Department of Mathematics in the Joint Faculty of Arts and Science at Dalhousie and King's Universities this September The position will be that of Lecturer (salary $3,000 to $4,000) or Assistant Professor ($4,000 to $5,000) depending on qualifications There is a good possibility of the position being permanent after two years. The work will probably involve teaching three undergraduate classes and one advanced class, three times each week from late September to late April.—Further information can be obtained from and all applications should be made to Dean of Arts and Science, Dalhousie University, Halifax, Nova Scotia.

MANCHESTER COLLEGE OF TECHNOLOGY

(FACULTY OF TECHNOLOGY IN THE UNIVERSITY OF MANCHESTER)
APPOINTMENT OF LECTURERS IN MECHANICAL ENGINEERING

The Governing Body invites applications fro University Graduates for two Lectureships Mechanical or Production Engineering in th College of Technology with the title and status o Lecturer in the University of Manchester. Th Department covers a very wide range of aspec of Mechanical and Production Engineering, an all members of staff are expected to undertak assist in or supervise research, for which the Department is excellently equipped There is particular need at present for men interested in Flui Mechanics and Hydraulic Servomechanisms an the fundamental processes of Production Engineering. Graduates in Physics might well be considered if they had special interests of value t the Department. Salary, £650 per annum, rising by annual increments of £60 to £1,350 per annum. Commencing salary according to qualifications Superannuation under the F S S U. Family allowances.

Conditions of appointment and form of application may be obtained from the Registrar College of Technology, Manchester, 1 The las date for receipt of applications is Friday, June 1956.

B. V. BOWDEN,
Principal of the Colleg

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF INDUSTRIAL METALLURGY

Applications are invited for a Lectureship in Industrial Metallurgy. The appointment will b in Grade II (salary £650 by £50 to £1,350 pe annum, with efficiency bar at £900, according t qualifications and experience, plus F S S U an family allowance) Applicants should have experience in crystallography, and in applications o X-ray diffraction techniques in metallurgy In addition, experience in some of the following field would be an advantage: radiography and othe methods of non-destructive testing, optical techniques of examination and instrumentation The lecturer will be required to take up his duties no later than October 1, 1956

Applications should be submitted by June 1 1956, to the Registrar, the University, Birmingham, 15, from whom further particulars may b obtained.

G. L. BARNES,
Secretary

The University,
Birmingham, 15.

CITY OF LEICESTER EDUCATION COMMITTEE

COLLEGE OF TECHNOLOGY AND COMMERCE

Principal: R E. Wood, M.Sc., F.Inst.P.

Applications are invited for the post of Assistant Lecturer (Grade B) in the School of Chemist from September 1, 1956. Applicants should have had an honours degree in chemistry and mus be able to teach one branch of chemistry up t B.Sc. special chemistry degree standard Industrial experience is desirable. Salary: Burnham Technical Scale, £525 to £820 (men) and £475 t £655 (women), plus degree and training allowances (and equal pay adjustments) and increments for approved teaching and/or industria experience and War Service.

Forms of application and further particulars can be obtained from the Registrar College o Technology and Commerce, The Newarke Leicester, to whom completed forms should b returned as soon as possible.

ELFED THOMAS,
Director of Education

ASTRONOMER ROYAL FOR SCOTLAND

PROFESSOR OF ASTRONOMY IN EDINBURGH UNIVERSITY

The Secretary of State for Scotland invites applications for the combined post of Astronomer Royal for Scotland and Professor of Astronomy in the University of Edinburgh.

Applications, accompanied by the names of three persons to whom reference can be made, should be addressed to the Private Secretary to the Secretary of State, St. Andrew's House, Edinburgh, 1, and should reach him not later than May 31, 1956 Three copies of the application should be provided A note of the terms of appointment and conditions of service will be supplied on request.

ELECTRIC MELTING
AND
SMELTING PRACTICE
By
A. G. E. ROBIETTE, M.Sc.

The book deals exhaustively with the principal types of electric furnace favoured in Great Britain and abroad, and discusses many new processes and techniques. The principles of operation, and the chemistry of the many different processes, are clearly explained. Special attention is given to changes in design of plant due to increasing size and mechanization—though the users of small and laboratory-type furnaces will find their requirements equally well catered for.

CONTROL OF GOVERNMENT RESEARCH IN BRITAIN

THE Department of Scientific and Industrial Research Bill*, which received its third reading in the House of Lords on April 17, is the outcome of a report of a committee of inquiry into the organization and functioning of the Department in the light of recent developments in science and industry which he had set up last year under the chairmanship of Sir Harry Jephcott. Besides Sir Hugh Beaver, the present chairman of the Advisory Council for Scientific and Industrial Research, its members included Sir Alexander Todd, chairman of the Advisory Council on Scientific Policy, the Deputy Secretary to the Board of Trade and the Third Secretary to the Treasury. The interim report of this Committee† has been published, but the final report, containing detailed suggestions regarding the internal organization of the Department, is not to be published.

The Committee's investigations led it to the firm conclusion that the organization of an ordinary government department is unsuited to the research activities of the Department of Scientific and Industrial Research, and that, under the present organization, the central direction of the scientific effort at the various research stations, taken as a whole, is inevitably inadequate to secure the most effective use of resources in the national interest. Allocations of man-power and money are determined by headquarters, but headquarters does not and cannot exercise an effective supervision over priorities in the programmes or even the balance between them. Much is started, but not enough is stopped and, as a result, many of the programmes have become too diffuse or too uneven in quality.

The latest report of the Department (see *Nature*, April 28, p. 821) shows that the Advisory Council is well aware both of the importance of discontinuing programmes and also of dropping work which the Department is only able to pursue on a trivial scale compared with what is being done elsewhere. Neither the Advisory Council, in commenting on this point, nor the Jephcott Committee points out, however, that the decision when to discontinue a programme is the most difficult that confronts a director of research. It is, in fact, difficult even for those engaged in the research to judge how near to success or how far from it a programme may be at a particular moment; and from that point of view it is almost impossible for those not in direct contact with an investigation to make a sound decision whether to continue or to stop the work.

The imminence or not of success is not the only consideration. Factors quite unrelated to the programme itself may make the success of the investigation a matter of far less interest to the country than when it was started, while new and more urgent matters demanding investigation may have arisen. It should not be assumed that even the director of a particular research station, however authoritative and distinguished in his own field, is necessarily aware of all such changing circumstances, and the Jephcott Committee may well have over-estimated the part of organization when it lays the whole responsibility for the present position on organization. The Committee recognizes rightly that no one scientist, however distinguished, in the capacity of secretary, could be expected to exercise a tighter control. Ministerial control, it emphasizes, is rightly and necessarily light; but it appears to attach too much importance to the fact that the Advisory Council is only advisory and, though it can have general influence, does not control the programmes.

The Jephcott Committee believes that the better direction of the Department's research activities which is needed can only be obtained effectively by introducing into the chain of responsibility, as high as may be, a number of distinguished scientists and industrialists whose professional authority will be recognized by all concerned, and particularly by the directors. Accordingly, its principal recommendation is that, in place of the Advisory Council, there should be created an executive council on the model of the Medical Research Council and the Agricultural Research Council. The Committee suggests that it will be easier to get men of the high quality required to give the time and attention that will be needed if they have a full responsibility to the Minister for the Department's activities and are not merely asked for advice.

The chairman of the proposed Council would not have powers of his own; decisions would be decisions of the Council. Its members would be part-time and not Civil servants, though it is anticipated that at the start the chairman would have to give a great deal of his time to the task. The secretary would be the chief executive of the Council and responsible for the conduct and activities of the staff of the Department. The Council, it is suggested, should not be too large and it would act largely through committees, recommendations regarding which were reserved for the second report. These committees would examine the programmes of the stations with the directors; and the Council would approve the programmes of the committees, confining itself normally to general questions of policy and the balance of activities within the Department, apart from points to which the relevant committee directs its attention or on which the relevant committee and the director are not agreed. While, as already indicated, the Committee does not consider a Vote-accounting department staffed by Civil servants to be the right organization for a research agency, it makes no recommendation on this point, and it is equally silent on the quinquennial principle, in spite of its bearing on the effectiveness of research as well as on the discontinuance of projects.

---

* Department of Scientific and Industrial Research Bill (H.L.). Pp ii+4. (London: H.M. Stationery Office, 1956.) 6*d*. net.

† Department of Scientific and Industrial Research. Report of a Committee of Enquiry. Pp. 4. (Cmd. 9734.) (London: H.M. Stationery Office, 1956.) 4*d* net.

The Bill now before Parliament is based on the principal recommendation of the Jephcott Committee and proposes to place the Department of Scientific and Industrial Research under a research council, the members of which will be appointed by the Lord President of the Council after consultation with the President of the Royal Society. The research council will be required to comply with directions given by the Committee of the Privy Council of Scientific and Industrial Research. Lord Salisbury said that, though the appointment of the members of the research council and of its secretary would be in the hands of the Lord President of the Council, he was sure that the Lord President would continue in the future, as in the past, to consult the Royal Society before making the latter appointment. He also added that he understood that the Royal Society was in agreement with the proposals in the Bill, and that it was the Government's intention to retain the present relation between the Royal Society and the National Physical Laboratory, subject to discussion with the Royal Society of any changes of detail in these arrangements which may seem necessary from time to time.

Neither in the interim report of the Jephcott Committee nor in Lord Salisbury's speech in introducing the Bill was any evidence advanced in support of the view that an executive council would be more effective than an advisory council in directing the work of the Department, or in securing the discontinuance of programmes no longer of public expediency where the relevant director had failed to stop the work. Lord Salisbury, moreover, emphasized that there was nothing radically wrong with the present Department, which has done and is doing extremely valuable work, and he paid a warm tribute to the work of Sir Ben Lockspeiser as secretary and to those who had served as members of the Advisory Council and its committees, pointing out that it was intended that the future research council should be recruited from the same type of eminent leaders of science and industry as had served in the past on the Advisory Council.

In the debate, Lord Wilmot of Selmeston, while agreeing that a full report of this character could not very well be made public, asked for more information about the contents of the report. He was disturbed that the Jephcott Committee made no recommendation about the organization of the Department, although it did not consider that a Vote-accounting department staffed by Civil servants would be the right organization for a research agency. He also pointed out that the Department of Scientific and Industrial Research is only a fragment of the Government's research effort, and asked for more information about the whole layout of Government expenditure in money and staff and about the Government's use of all scientific man-power. Asking how much was being spent by the Government on scientific research generally, he suggested that, before the Committee stage of the Bill, the Government should provide a comprehensive statement showing the total expenditure on scientific research and its broad distribution. Without information of this character, he pointed out, we cannot judge whether we are making the best use of our scientific man-power.

Referring to the request for information as to Government expenditure on research, Lord Salisbury reminded Lord Wilmot of the annual reports of the Advisory Council on Scientific Policy. While, however, the eighth report of that Council summarized in an appendix Government expenditure on civil research and gave some details of the scientific staff working under the research councils, it does not meet a number of points on which Lord Wilmot asked for information. No account is taken of expenditure by the Atomic Energy Authority, the Ministry of Supply and the Admiralty; the nationalized industries are likewise not covered, nor are we given any information as to expenditure on private research contracts, for example, by the public departments to aircraft firms or about research projects in other industries financed by the Government under the heading of development and research. Nor is there any estimate as to the proportion of £34 million that the University Grants Committee distributes to the universities and university colleges which is expended on research.

Without such information, however, it is impossible to judge the soundness of the criticism of the administration of the Department of Scientific and Industrial Research made by the Jephcott Committee, or the appropriateness of the place the Department holds in the national organization for research. All that can be said is that no evidence is forthcoming in either the Department's last annual report or in the interim report of the Committee to substantiate those criticisms, or to justify the belief that an executive council is likely to be more effective than an advisory body in securing the wise expenditure of the Department's vote. In the House of Lords debate, Lord Wilmot asked some of the right questions; but neither Parliament nor the world of science or technology has yet been given the information essential for a sound judgment as to the validity of the Committee's criticisms or the effectiveness of the administrative changes proposed.

At the Committee stage on April 17, Lord Cherwell expressed anxiety that the new council might not give enough attention to scientific research, and particularly to its support at the universities. Lord Salisbury affirmed that there is no intention of withdrawing such support or of limiting the powers of the Department to encourage and support scientific research in the universities. While agreeing to consider further Lord Cherwell's points, he said that under Sub-section (4) of Clause 1 the Department would possess powers to make grants for postgraduate instruction in science and technology, which it did not previously enjoy. At the third reading, on April 19, Lord Cherwell agreed that the amended clause made it abundantly clear that scientific research in the universities as well as industrial research will be supported.

Little was said in the House of Lords about the second main purpose of the Bill, to which effect is given in Clause 3. This, as Lord Salisbury explained, arose out of a technical point raised by the Public Accounts Committee, and, while it means no change in the present arrangements for the Parliamentary control of the finances of the Department of Scientific and Industrial Research, provides that the Department's expenditure shall be met out of monies provided by Parliament. There is, however, no reference to making grants on a quinquennial system, and this aspect should be probed rather more fully in the House of Commons than was done in the House of Lords. It is unsound to insist on retaining close Parliamentary control if, in fact, that tends to lead to waste of resources of either finance or of man-power.

The most surprising aspect of the whole situation is that the Bill should have been introduced without any reference to the Advisory Council on Scientific Policy. There was no suggestion in the last annual report from that Council that any change in the administration of the Department of Scientific and Industrial Research was contemplated or required. Indeed, the reference in that report to the discontinuance of seaweed research suggests that the existing structure provides for the discontinuance of broad lines of research when appropriate, even if not necessarily to the full extent that is desirable. It may well be time for the whole structure and organization of the Department of Scientific and Industrial Research to be reviewed; but that can only usefully be done if the organization of the research effort in Britain as a whole is also considered. Such a review will necessarily include the place of the Advisory Council on Scientific Policy and the position of the Lord President of the Council in the co-ordination and administration of the country's research effort in defence as well as in civil affairs. Now that the matter has been raised, men of science as well as Parliament should insist on being given the information essential for sound criticism and reasoned judgment as to the proposals before Parliament and all their implications.

EPIGENETICS

Principles of Embryology

By Prof. C. H. Waddington. Pp. x+510. (London: George Allen and Unwin, Ltd., 1956.) 45s. net.

In his first chapter, Prof. Waddington suggests 'Epigenetics' as "perhaps the most satisfactory expression" to denote the analytical study of development. In spite of this, he has stuck to 'Embryology' in his title, though he makes it plain that no line can properly be drawn between embryonic and post-embryonic development, between early and late stages of ontogeny. However, a good title provides a banner under which a new scientific movement can advance (witness 'gene' and 'genetics' in the study of heredity). Accordingly, *I* am going to have the courage of *his* convictions: I shall use 'Epigenetics' as meaning the science of developmental process in general, and hope that others will do the same.

Though separate aspects of epigenetics have been treated in various recent books, including the huge composite work, "Analysis of Development", edited by Willier, Weiss and Hamburger, the "Principles of Embryology" is, so far as I know, the first comprehensive and unitary work on the subject since 1934, when de Beer and I published "The Elements of Experimental Embryology".

Knowing by experience the immense amount of labour, both compilatory and critical, that is involved in any such enterprise, my first and agreeable duty, on behalf of all general biologists, is to thank Prof. Waddington for having undertaken the task, and to congratulate him on the result.

Part 1 is entitled "The Facts of Development". It gives a descriptive-analytical treatment of early development in some selected groups of animals (with a natural emphasis on vertebrates, but including summaries of echinoderm, chordate and insect epigenetics) and chapters on growth and regeneration. Throughout, the treatment is centred around the general concepts which are emerging from analysis on the epigenetic level, such as organizer action, induction, evocation, competence, individuation, gradient-fields, and canalized epigenetic pathways.

Part 2 deals with "The Fundamental Mechanisms of Development". Most of it is concerned with a new angle of approach—a general analysis of the relations between genetics and epigenetics, between genes and their effects. Waddington attacks the problem from both ends, on one hand working upwards to trace the biochemical and other effects of particular genes or gene-complexes, on the other digging down from phenotypic effects in an attempt to uncover their genetic basis. This leads on, via phenocopies, to the subject of developmental reactivity, to which (and to its evolutionary implications) the author has made so original a contribution. There is no one else now alive who is equipped both as a geneticist and an embryologist to undertake this task: in the result he has taken an important step forward in epigenetic theory, and is charting a large new area for further research.

I will say no more about the work's positive achievements, beyond the fact that it will clearly be indispensable not only for embryologists and *Entwicklungsmechaniker*, but also for all general biologists. My critical comments, indeed, are a tribute to its value in stimulating trains of thought, some of which I hope may be useful in suggesting improvements in the further editions that I am sure will be speedily called for.

My most general comment is that, though Waddington has done so much to link epigenetics with genetics, he has not proceeded to make the further link with evolution. This in my view can only be done by recognizing the pseudo-teleological, or as I would prefer to say, the *telic* character of all evolutionary processes and resultants. By telic I mean that, thanks to the operation of natural selection, such processes can only be adequately specified in terms of final states or ends as well as of origins or beginnings, of biological utility or function as well as of underlying mechanism or mode of operation. Thus, though analysis of epigenetic process in terms of physico-chemical factors is essential, it will never be sufficient, and knowledge of origin needs to be supplemented by knowledge of final fate (for example, in the axial skeleton). Recognition of this makes many facts of epigenetics more comprehensible (as well as often indicating further lines of research)—for example, the evolution of dominance, the greater stability of wild-type as against mutant characters, and (what Waddington rightly stresses) the canalization of developmental processes into a limited number of "epigenetic paths", each showing considerable powers of self-regulation or homeostasis. The limits of such paths or patterns of process must have been set by rigorous selection; for a process which led to an abnormal or imperfect organ or tissue, or still more to one intermediate between two different kinds of organ or tissue, would be promptly selected out of existence. That such telic pathways must have been built up by selection during evolutionary time is demonstrated by their frequent destruction by hybridization. Wide crosses in *Antirrhinum* lead to many abnormal organs, in *Nicotiana* to tumorous growths, and in some fish crosses to malignant melanomas. In the course of genetic recombination, the telic patterns have been taken to pieces.

Such an approach would, I think, have made a difference to Waddington's discussion of 'competence'. For him competence is "a state of unstable equilibrium", and competent tissues are those which are balanced on a knife-edge between two or more alternative and distinct modes of differentiation: for example, early ectoderm can form either epidermis or neural tissue according to the evocatory stimuli which act on it. To begin with, it would appear that such tissues should be called bicompetent (or multicompetent) and that 'competence' should be generalized so as to include also unicompetence or the capacity to proceed only along one epigenetic pathway. Furthermore, the metaphor of unstable equilibrium is unsatisfactory: bicompetence is best assimilated to those numerous epigenetic phenomena where a switch-mechanism is operative. In such cases, alternative causes or stimuli switch development into alternative pathways, each of which has been sharply delimited or homœostasized (stabilized) by past selection. As with a railway switch, there need be no instability, whether on the single pathway before reaching the switch, or on either of the alternative tracks along which the process may continue.

It is indeed rather surprising that Waddington has not paid more attention to switch-mechanisms such as alternative sex-determination and mimetic polymorphism. In these the relation between genetics and epigenetics, as well as the telic need for sharply defined alternative pathways, is particularly evident: neither intersexes nor inaccurate mimics are of any biological utility, though both can be produced by genetic manipulation of the switch-mechanism.

A chapter devoted to metamorphosis, especially in amphibia, would have been well worth including, primarily as an example of hormone-dependent processes in development. It could also have illustrated the important point that, in a developmental reaction, variations in the capacities (or competence) of the reacting tissues may be more important than those in the properties of the evocating agent. Thus in amphibian metamorphosis the limbs and tail react to thyroxin quite differently in Anura and in Urodela, while in Perennibranchiates no tissues are competent to react to thyroxin at all. In addition, of course, the supply of thyroxin may be quantitatively altered, even to abolition as in some Perennibranchiates, or its time-relations changed, as in the neotenous axolotl. The comparison of anuran and urodele metamorphosis illuminates the evolution and epigenetics of specialized larval forms, and the effects of temperature have a general importance for endocrinology.

A chapter on sexual bicompetence, if space had permitted, would also have been valuable. In metamorphosis, two alternative end-states succeed each other in time: in sexual differentiation, they are contemporaneous. Furthermore, in insects there is only a single (genetic) switch-mechanism for the development of sex-limited characters: in vertebrates, a primary genetic switch leads on towards a later endocrine switch-mechanism.

In some cases the switch is operated environmentally, for example, in the sex-determination of *Bonellia* and in the differentiation of the alternative types of leaf (aerial and aquatic) in *Ranunculus aquatilis*.

A subject which would have repaid further analysis is reconstitution after cellular dissociation, as in sponges (where the morphogenetic effects of cellular orientation and migration are well exemplified). Another is the morphogenetic effect of mechanical stress, as evidenced by the fine structure of bone and by Weiss's beautiful experiments on the response of fibroblasts to tension. Yet another is that of dedifferentiation followed by resorption, which brings out clearly the existence of a physiological balance between organ-systems: thus in unfavourable conditions the larval tissues of an *Echinus* larva start to dedifferentiate, and are finally resorbed and utilized by the *Echinus* rudiment, which accomplishes a premature metamorphosis. Resorption may also be initiated by radical degeneration of tissue instead of by a mere tilting of physiological balance. Such tissues exhibit a specific competence for 'degeneration-proneness' in response to particular evocators: the best-analysed case is that of the resorption of tadpole skin in contact with degenerating gills. The analysis of tail-resorption in anuran metamorphosis deserves further investigation, as does the fact that whenever ectoderm and endoderm become apposed in early vertebrate development, perforation occurs (resulting in the formation of mouth, gill-clefts and anus).

More might have been made of the three different types of cellular dedifferentiation. We have first what Waddington calls true dedifferentiation, or one might say dedetermination, in which cells lose their determination and revert to a pluripotent state, as in some regenerative blastemas. Then there is hypoplastic dedifferentiation, the loss of visible differentiation only, which accompanies rapid multiplication, as in tissue culture or in tumours*; and finally there is anabiotic dedifferentiation, or passage into a resistant and inactive state, as in protozoan cysts or the cold-resistant cells found in some deep-frozen tumour tissues. Perhaps more attention might have been given to the determination of polarity, notably to the rare but interesting cases in which primary (antero-posterior) polarity is determined environmentally, as in *Fucus* eggs. In general, plants might have been drawn on to a considerably greater extent for illustrative examples.

In the valuable discussion of developmental gradient-fields, more stress might have been laid on their *Gestalt* character, notably the fact that their pattern is only deformable as a whole. Thus even when a large local change occurs in a growth-gradient, as when one sex evolves an unusually large organ (chela, abdomen, or the like) it affects the growth-rate of neighbouring organs in an orderly (though as yet quite unexplained) way: similarly in regenerating flatworms, depressants alter the size and form of the morphogenetic gradient-field as a whole. Curiously enough, no mention is made of the continuous gradients revealed by the growth of molluscan shells or of localized areas of excessive proliferation (as in rhinoceros horns), or of the change from positive to negative allometry, with consequent deformation of the whole growth-gradient, during evolution as in the antlers of roe-deer, or during ontogeny as in the limbs of ungulates.

---

* *Anaplastic* would be a better term, but unfortunately anaplasia has been pre-empted by oncologists to denote total loss of histological differentiation, and usually with the implication of regression to an embryonic pluripotent state.

There is no mention of Witschi's demonstration that moderate delay of fertilization in Anura deviates the sex-determining mechanism, while greater delay upsets the growth-balance and leads to tumorous proliferation. Indeed, the chapter on growth could profitably have included a section on abnormal and cancerous growth.

I realize that reasons of space must have precluded the inclusion of many of these subjects. However, I hope that in any future revision the size and scope of the work will be enlarged to permit their inclusion.

The discussion of embryonic induction is, as one would expect, both thorough and illuminating. But it left me wondering whether it, or at least its terminology, was not somewhat bedevilled by the history of the subject. Should not the term 'organizer' now be dropped? Again, should not 'evocation' and 'competence' be assimilated to comparable phenomena in other stages of developmental physiology? Is there, for example, any essential difference between the 'induction' of neural tissue by the evocator of the blastopore lip and the 'modulation' of the basal layer of the epidermis into mucous epithelium by vitamin A, or the development of the sexual apparatus of the two sexes under the influence of the appropriate sex-hormones? Here, as in many other places, epigenetics is entering new domains. For example, the facts concerning viruses, plasmagenes, and transduction (admirably though rather briefly discussed by Waddington), together with the proof recently given by Medawar and his associates that many tissues are constantly discharging nucleoprotein particles into the circulation, are opening up wholly new vistas of genetic and epigenetic interaction.

Let me conclude by again expressing my gratitude to Prof. Waddington for this valuable and stimulating book, and my hope that he will in the not too distant future supersede it by a new and even more comprehensive work on the "Principles of Epigenetics".

JULIAN HUXLEY

PRIMEVAL MICROBES

Biochemistry of Autotrophic Bacteria

By Dr. Howard Lees. Pp. viii + 112. (London: Butterworths Scientific Publications, 1955.) 21*s*.

THE autotrophic bacteria may be considered as survivors of the first living organisms to appear on Earth; like the green plants they assimilate carbon dioxide, but they show great variation in the mechanism of assimilation, which perhaps indicates that they are trial pieces in the evolution of more efficient and successful types of metabolism than they themselves possess. Some use light as a source of energy; others, lacking pigment, use the oxidation of a specific inorganic compound. Other species oxidize organic compounds for energy, but cannot assimilate them; and finally there are species which normally are heterotrophic, but can carry out certain autotrophic reactions.

The autotrophic bacteria, however, are important not merely as picturesque survivors, or for studies in comparative biochemistry. They have great practical importance. Without the nitrates made by autotrophic nitrifying bacteria, farming would be impossible; and other autotrophs produce sulphur, and purify the air by assimilating carbon monoxide. On the debit side are the activities of species which cause stone and concrete to decay, corrode buried iron pipes, and produce hydrogen sulphide in standing water, and even sometimes in the sea.

Dr. Howard Lees has now written a short book on the biochemistry of these bacteria, in which most of the available knowledge is collected from very scattered sources. It covers the field very well, and the varieties of metabolism are lucidly explained. He is more interested in the philosophical than the practical aspects of the subject, and writes on evolution with far more conviction than on ecology. There are some faults of style, notably a fondness for words like 'overall' and 'subsume'. Careless proof-reading must account for the appearance of 'oxidized' in one place where 'reduced' is obviously meant, for the curious double plural 'flagellæ' which has crept in on p. 35, and for the explanation of the Calvin cycle in the appendix, which is a year out of date though the diagram is contemporary.

JANE MEIKLEJOHN

AUXINS AND PLANT GROWTH

Auxins and Plant Growth

By Prof. A. Carl Leopold. Pp. xi + 354. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1955.) 37*s*. 6*d*. net.

AS the title indicates, this book is concerned only with auxins, namely, β-indolylacetic acid and the many compounds (natural and synthetic) which are related to it chemically and which exert the same remarkable growth-controlling actions in green plants. Prof. A. C. Leopold introduces the reader to his book by expressing alarm at the widespread lack of knowledge of the fundamentals of auxin physiology among research workers concerned with the uses of these compounds in agriculture, and the book is intended to alleviate this unfortunate state of affairs. Prof. Leopold has attacked the problem with vigour and has succeeded in laying before the reader the auxin situation in all its puzzling complexity.

The book falls naturally into two parts. The first half (eight chapters) deals with the fundamentals of the action of auxins and includes their chemical nature, occurrence, metabolism and biochemical mechanisms, the whole being preceded by a clear, if somewhat limited, historical introduction. A chapter on extraction and measurement techniques should form a useful basis for practical exercises by the student. Two chapters are devoted to physiological, anatomical and developmental effects, and a balanced, though restricted, picture emerges of the many parts natural auxin may play in plants. The second half (ten chapters) is concerned with auxins in agriculture and deals in a logical and comprehensive way with the many uses to which these remarkable compounds have been put. As one would expect from the title, no attention is given to the host of 'growth-regulators' not related to auxins, except the few (for example, maleic hydrazide, ethylene, etc.) that are suspected of interfering with natural auxin action. The main aspects dealt with in detail are rooting, flower and fruit production, dormancy and storage, and weed-killers. A miscellany of 'incidental' uses is also included. Much fundamental physiology has, of necessity, been introduced into these chapters on practical applications, and this has led to repetitions and overlaps with sections in the first half. It is a pity that, in a book intending to bring practice into closer contact with theory, such a divorce should have been thought necessary.

The book is illustrated with a great profusion of simple graphs re-drawn from original research articles. The majority are well and aptly chosen and serve, as indeed should all scientific illustrations, to clarify the text and avoid much tedious description. Here and there, however, the author's enthusiasm gets a little out of hand, and figures of such simplicity appear that it is difficult to see what purpose they serve. Fig. 68, in which three graphs are drawn through six 'arbitrary' points, is perhaps the worst example. I find the literary style occasionally a little disconcerting; for example, the obscurity of the sentence: "Enzymology readily recognizes the inhibition of reactions by compounds of slightly different properties from those of true substrates" (p. 165).

The book ends with a guess at the future and a warning of the dangers of promoting technology at the expense of fundamental research. The warning is indeed timely, and it is to be hoped, therefore, that Prof. Leopold's book will be widely read. The format and binding are excellent. There is an extensive bibliography of some eight hundred references, the majority of which are from American journals.

L. J. AUDUS

PREPARING ENZYMES

Methods in Enzymology

Edited by Sidney P. Colowick and Nathan O. Kaplan. Vol. 1: Preparation and Assay of Enzymes. Pp. xxv+835. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 18 dollars.

THOSE actively engaged in the field of enzymology have long felt the need for an authoritative text-book dealing with the isolation and assay of enzymes. The theory and kinetics of enzyme action have been the subject of many recent books and symposia, but a work which gives adequate practical details for the preparation of many common enzymes has not been forthcoming. Such a series is being prepared under the editorship of Drs. S. P. Colowick and N. O. Kaplan, of Johns Hopkins University, and this is the first of four volumes.

In their preface to the series, the editors state that this series should serve as a companion piece for Sumner and Myrbäck's classical work, "The Enzymes", and the present volume gives every indication of this claim being justified. There are more than a hundred and twenty articles contributed by nearly the same number of recognized experts in the enzyme field. The volume is divided into four sections, the first dealing with general preparative procedures. This is eminently readable without being too theoretical in its approach, and should serve as a useful technical basis for the investigation of new enzyme systems. The articles dealing with the variety and applicability of methods of purification are, on the whole, well written and serve to illustrate the advances that have been made in technique during recent years.

The last three sections are concerned with the specific enzymes of carbohydrate metabolism, lipid metabolism and the citric acid cycle. A method for the isolation and assay of each enzyme is given in detail, together with information, where available, concerning optimum conditions, specificity, activators, inhibitors and other data of particular use to the growing number of those who wish to use enzymes as tools in their investigations. The section on carbohydrate-metabolizing enzymes is reasonably well covered, the emphasis, however, being rather on the side of those occurring in animals and micro-organisms. In particular, although plant phosphorylases and amylases are treated at length, other equally well-characterized enzymes concerned in the synthesis and breakdown of starch in higher plants are neglected. Thus some mention was to be expected of the plant branching-enzyme, *Q*-enzyme, which has been obtained in crystalline form. The section on lipid metabolism also has good general coverage, and the section dealing with enzymes of the citric acid cycle is both adequate and up to date. Compared with these two sections, the section on carbohydrate metabolism is rather large and unwieldy and might conveniently have been subdivided.

There is an occasional reference to trade products and equipment by name without further definition and with little reference to working details. In certain cases this has an adverse effect on intelligibility for the non-American reader. Nevertheless, this volume is well worth having in any laboratory where enzymes are studied or used. The system of cross-references and the bibliography, which includes references up to 1953, are adequate and help to ease the burden of searching through the literature.

J. R. TURVEY

DAIRY SCIENCE AND PRACTICE

A Dictionary of Dairying

By Dr. J. G. Davis. Second edition, revised and enlarged. Pp. xxviii+1132+132 plates. (London: Leonard Hill, Ltd., 1955.) 65*s*. net.

THE author of this most useful reference book, a well-known dairying consultant, has evidently been in somewhat of a quandary to find an appropriate title. "Dictionary" is a trifle misleading. Though "Encyclopædia" would probably have been too grandiloquent, the approach of the author is that of an encyclopædist rather than that of a lexicographer. He seems, too, to have been a little diffident in defining what is meant by 'dairying', a word with different connotations for different authorities dealing with the underlying science and its practical application. The precise definition which I had hoped to find is, in fact, not given in the text; on the other hand, if dairying does need an up-to-date definition, then the ground covered by this volume can reasonably be regarded as providing a sufficient one.

It is clear that the author is firmly of the opinion that dairy science and dairying cannot be interrupted by the accident of the farm gate—their scope, in fact, covers everything that happens from (and including) the farm production of milk, through its various types of processing for consumption as liquid milk or its manufacture into dairy products, up to its consumption in one form or another. This is a view with which most of those concerned with dairy science or practice would agree, not least because so many of the problems of milk processing and manufacture are bound up with the efficiency or lack of efficiency of dairy farm management and milking technique.

The scientific disciplines and the technological skills—agricultural, physiological and veterinary, bacteriological and biochemical, engineering and physical—needed to-day to deal with the problems and practice of dairying on both sides of the farm gate cover tremendously wide fields, as is so clearly evident from even a cursory glance at this 1,100-page volume. Nor does the author omit substantial reference to the fact—which is perhaps likely to be forgotten in peace-time—that milk and milk products are still the most valuable, from the point of view of human nutrition, of all our common foodstuffs.

In compiling this work, the author, though himself responsible for large, well-informed and well-written sections of it, has received the contributions of a number of specialists in particular fields. To name two such contributions only, there is an excellent epitome of modern knowledge of milk secretion by A. T. Cowie, and a chapter on legal aspects by A. L. Barton and P. O'Neill which is a model of concise and accurate statement of milk legislation in Britain. But in these two contributions, as in so many others dealing with the changing aspects of dairying, periodical revision is essential, and it is to be hoped that the author will find time to shoulder this heavy task at, say, five-year intervals.

To be without ready access to this excellent compilation is a mistake which few in any consultative, scientific, technological or managerial position in the dairy industry, and which no student of dairy science or practice, can afford to make. H. D. Kay

RECENT ADVANCES IN STEREO-CHEMISTRY

Progress in Stereochemistry
Edited by Dr. W. Klyne. Vol. 1. (Progress Series.) Pp. x+378. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1954.) 50*s.* net.

FIFTY or sixty years ago the study of stereochemistry was almost entirely limited to attempts to discover the orientation of various groups of valency bonds around different atoms by methods analogous to those that had been used for showing that the four valencies of the carbon atoms are directed to the corners of a tetrahedron. However, even at that time, the subject was expanding, as is shown, for example, by Werner's interest in the changes in configuration that occurred at a cobalt atom when certain substitutions of one group by another took place.

Since that time stereochemistry has become important in all branches of chemistry. This is well illustrated by the most interesting book that is under review here, for contained in it are sections concerned with reaction kinetics, spectroscopic properties, the configuration of proteins, enzyme processes, as well as sections which derive more directly from the studies and ideas of Van t'Hoff and Werner.

The book is one in which a number of authors have contributed chapters each dealing with that part in which he is specially expert. As a consequence, the book is a collection of quite separate articles. The first of these, by A. D. Walsh, is concerned with the shapes of simple molecules and contains, besides a valuable discussion, an extremely useful and complete tabulation of data on bond angles. These are now known with increasing precision since microwave spectroscopy has been added to the methods used in their determination. The second chapter, by W. Klyne, who has also edited the book, deals with the conformation of six-membered ring systems and provides a most readable and interesting account of this subject. The long list of references at the end of this chapter shows the great interest that exists in it at the present time. The effect of stereochemical factors in chemical reactions is the subject of the next chapter, which is by P. B. D. de la Mare, a member of the group at University College, London, which has contributed so much to this part of the subject. R. S. Nyholm also deals with the stereochemistry of substitution reactions at complex ions in his chapter on complex compounds. Some relationships between stereochemistry and spectroscopy are examined in Chapter 4. Most of this chapter deals with absorption in the visible and ultra-violet, but there is a considerable section on vibrational infra-red spectra. There are three chapters concerned to a large extent with matters of biochemical interest. One deals with the configurations of large molecules and, in particular, of proteins, and another with the fascinating subject of the stereo-specificity of enzymes. There is also a chapter on the stereochemistry of the hydrogen bond.

The articles included in this book reach in general a very high standard. They will be interesting and useful to the specialist and also to the more general reader. The tables and graphs are well done and the lists of references at the end of each section are extensive and up to date. They add greatly to the value of this publication, which should be most enjoyable and stimulating to chemists at all stages of training and achievement. J. W. Linnett

NEUROCHEMISTRY

Neurochemistry
The Chemical Dynamics of Brain and Nerve. Edited by K. A. C. Elliott, Irvine H. Page and J. H. Quastel. Pp. xii+900. (Springfield, Ill.: Charles C. Thomas; Oxford: Blackwell Scientific Publications, 1955.) 140*s.*

AUTHORITATIVE and comprehensive accounts of the chemistry of the nervous system are few and far between. Apart from the original classical work by Thudichum in 1884, the only recent extensive publications have been the books by Page which appeared in 1937 and by McIlwain which appeared in 1955. Consequently the volume under review, compiled by thirty-two authorities on the subject, is indeed welcome.

It begins with an introductory chapter appropriately devoted to Thudichum, the father of the subject. It is unfortunate that in this fairly extensive account of Thudichum's life, much of it spent as a practising physician, no mention is made of the fact that in 1865 he was appointed lecturer in pathological chemistry at St. Thomas's Hospital, although it is noted that seven years previously he had been appointed lecturer in chemistry at Grosvenor Place School of Medicine.

The book covers all aspects of the biochemistry of the nervous system. It includes sections on the chemical constituents of nervous tissue, the mechanism of respiration, glycolysis and oxidation, nerve function, acetyl choline, intracranial fluids, electrolytes, neurotropic drugs, neurotoxins and snake venoms, the toxic effect of oxygen, aspects of narcosis, convulsive conditions, nutritional disorders, the nervous system in arthropods, and concludes with a chapter on the thermodynamics of the message. It will be clear, therefore, that although much of the material is fundamentally biochemical in nature, it also covers a much wider field, and the contributors range from neurologists to mathematicians.

Three main criticisms may be levelled at this book. The first and least important is that inevitably much of the material described in the chapters dealing with metabolism, glycolysis, respiration and oxidation, comes under the heading of general biochemistry and is to be found in any text-book of biochemistry, since the fundamental steps in these processes are not peculiar to the nervous system.

The second criticism is that the book suffers severely from those defects which are inevitable in any work of multiple authorship. It is, in fact, a series of isolated essays dealing with different aspects of the metabolism of the central nervous system but without much thread of continuity to connect them. This lack of continuity is more serious than is the fact that the various authors frequently and not unexpectedly express contradictory points of view. This is inevitable in any work dealing with debatable material discussed by each expert from his own particular angle. It is even stimulating to see the clash of personalities. For example, Nachmansohn in his chapter on "Metabolism and Function in the Nerve Cell" holds to the view that the role of acetyl choline in conduction is essential, whereas this view is strongly contested both by Gerard and by Burgen and MacIntosh.

A third and much more serious criticism is that much of the book is already out of date. The editors explain in the preface that most of the manuscripts were in their hands in 1951 and that some of them have been revised since then. Even so, some advances made in the past two or three years have been omitted. For example, Hyden's important chapter on "Nucleic Acids and Proteins" is up to date as far as 1950 and contains only a few references to work done between 1950 and 1953. Similarly, in Burgen and MacIntosh's masterly chapter, one of the best in the book, on the "Physiological Significance of Acetyl Choline", the section on p. 327 dealing with coenzyme *A* is seriously out of date, although an attempt has been made to modernize it in a footnote on p. 329 which mentions Lipmann's paper in the *Federation Proceedings* of 1953.

But, in spite of these criticisms, the book contains a wealth of valuable material which will not easily be found elsewhere, and it will undoubtedly remain for some time to come an authoritative work in this particular field.

J. N. DAVIDSON

NEUTRON CROSS-SECTIONS

Neutron Cross Sections

Prepared by the United States Atomic Energy Commission. (Selected Reference Material on Atomic Energy.) Pp. viii + 328. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 90*s*.

THE probability that a neutron interacts with the matter through which it is passing interests a surprisingly large number of people. There is the 'pure' interest of the nuclear and solid state physicists, and the 'applied' interest of reactor physicists, metallurgists and engineers. Alongside this there is the indirect interest of all those using radioisotopes and neutron irradiations for research in medical, biological and other fields.

This interest arises, of course, because of the utility of neutron interactions both as a research tool and in the production of power.

The probability of interacting with an atom in a given state is called the total cross-section for that atom, and its value will depend upon the energy of the neutron involved. Very often several types of interaction are possible, and then an attempt is made to divide up the total probability into partial cross-sections for each interaction. Since the development of the nuclear reactor and of powerful neutron sources associated with particle accelerators, a vast number of neutron cross-sections have been measured.

The task of compiling these cross-sections, from the small compilations already published and the original data, was undertaken several years ago by a compilation group of the U.S. Atomic Energy Commission at the Brookhaven National Laboratory. This compilation, *AECU*-2040, has been an invaluable handbook for everybody concerned with neutrons. Now it has been brought up to date and published as part of the selected reference material issued by the U.S. Atomic Energy Commission at the Geneva Conference on the Peaceful Uses of Atomic Energy.

The editors, Drs. D. J. Hughes and J. A. Harvey, are to be congratulated on the production of such a worthy handbook. It includes tables of thermal neutron cross-sections (absorption, activation, scattering and fission) and of resonance parameters, as well as graphs of the cross-sections between 10^{-4} eV. and 100 MeV. and the angular distributions of scattered neutrons. It will be appreciated that with such a mass of material available some kind of explanatory background book is required to be used in conjunction with the compilation. I understand that such a book is in course of preparation. For those not familiar with the interaction giving rise to the reported cross-section, such an adjunct is indispensable. In addition, some background information is often useful for the specialist; for example, the methods used in the compilation for choosing a 'best value'.

The cross-sections as a function of energy are shown on large graphs each covering a factor of 10^4 in energy. But in some cases difficulties of graphical presentation arise due to the complicated nature of the experimental data. Many of these difficulties are overcome by including with one of the large graphs an inset showing an expanded graph of the complex region. However, there are a few cases where the present uniform layout might be dropped altogether in favour of a more detailed presentation. This might include a table of values of cross-sections as a function of neutron energy. Due to the steady improvement of experimental techniques, the number of such cases is likely to increase rapidly, making the task of the compiler even more difficult than it is at present.

An additional piece of information, which might well be included in the tables and graphs, is the method of measurement used. Since many methods are used quite widely, a simple coding system should be possible.

It was a disappointment to find that the supplement to the compilation, which was made available to members of the Geneva Conference, was not attached to the present publication. This supplement included data taken from all sources on the cross-sections of the fissile isotopes, whereas the main compilation covers American sources only. Consequently, the supplement is invaluable to those interested in atomic energy. (The book, including the supplement, is also available in paper covers from the Government Printing Office, Washington, D.C., price 3.50 dollars.)

In conclusion, this well-presented compilation is as essential as its predecessors to everyone working with neutrons, and we all look forward to many future editions coming from the same source.

P. A. EGELSTAFF

THEORETICAL STATISTICS

Introduction to Mathematical Statistics

By Prof. Paul G. Hoel. Second edition. (Wiley Publications in Statistics.) Pp. xi+331. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1954.) 40s. net.

THIS is one of the best text-books on theoretical statistics at the undergraduate-level. The first edition was good, but this second edition has been revised, extended and greatly improved. It is very suitable for first-year students with a knowledge of elementary calculus and some general acquaintance with the scope of statistical method. There are numerous exercises, the answers to which can be obtained separately.

Prof. Hoel breaks away from the traditional course of development. An initial chapter on probability introduces the idea of a sample space on p. 4, before frequency distributions or their summarizing measures have been discussed. Models, testing hypotheses and estimation are dealt with in the following chapter. This sounds like putting the cart before the horse and, logically, perhaps it does so; but from the teacher's point of view there is much to be said for it.

The book then swings back more or less on course and deals with frequency distributions, sampling theory, correlation and regression, goodness of fit, the general principles of testing hypotheses, small sample distributions, design of experiments and non-parametric methods. The treatment throughout is fresh and clear. Prof. Hoel has succeeded in teaching the essential ideas without much mathematical complication and, at the same time, in providing enough exercises to enable the student to feel that he has mastered the details of the technique.

A few suggestions for further editions: would the author not consider 'theoretical statistics' a better expression than 'mathematical statistics', and 'distribution-free methods' better than 'non-parametric methods'? Moreover, could he not say something about the manipulative algebra of expectations and about generating functions, two subjects which, in my experience, give the greatest trouble to beginners?

M. G. KENDALL

THEODORE ROOSEVELT AS NATURALIST

Theodore Roosevelt's America

Selections from the Writings of the Oyster Bay Naturalist. Edited by Farida A. Wiley. (American Naturalists Series.) Pp. xxiii+418. (New York: The Devin-Adair Company, 1955.) 5.75 dollars.

THIS book is one of a series devoted to commemorating such famous American naturalists as were citizens of the United States, by publishing selections from their writings. Theodore Roosevelt was a most versatile as well as a most remarkable man, and an intense love of wild Nature was one of his greatest and most lasting interests. His knowledge of natural history was wide, and though he studied natural sciences, including zoology, for four years at Harvard, his defective eyesight compelled him to abandon the idea of making science his life-work. He entered politics instead, but after three years went on a hunting trip into the Bad Lands of the Dakotas to recuperate his health. He was so fascinated with the region, and with the life of the cattlemen, that he bought two ranches where he lived for the next two years as a stockman. Thereafter he returned to politics; but his experiences in North Dakota had left a deep impression on him and, indeed, formed a vivid background to the rest of his life.

Most of this book consists of Roosevelt's own writings about the Bad Lands, and the last two chapters deal with his expedition through tropical Brazil. The introductory matter by several hands entitled "Roosevelt as a Naturalist" on the whole does little service to his memory; but the subsequent chapters from the pen of the great man himself are very different, and at once arouse the reader's interest. There is probably no better account of life on a cattle ranch in the 1880's than Roosevelt's—he writes with sympathy, knowledge and understanding. His style is simple and direct, and gives a most vivid picture of the country with its human and other wild inhabitants. His accounts of the game animals, the birds, and the smaller creatures are first class, and his yarns about his cowboys and about his adventures with 'bad men' and other desperadoes are thrilling. It was a hard strenuous life, and he lived and enjoyed it to the full.

It was in later life that Roosevelt undertook his South American expedition, which turned out to be a laborious and at times a hazardous journey; he was perforce more of a passenger than he would have wished to have been. His account of it is interesting, but it has not the vitality of the chapters on the old days in Dakota when he was in full health and vigour.

A chapter criticizing the Thayers' book on revealing and concealing coloration in the animal kingdom, originally published many years ago, is of little present interest—the Thayers' principle of counter-shading is generally agreed, and all their fantastic nonsense has long ago been forgotten. A short chapter "In Defence of our Natural Heritage" reminds the reader that Roosevelt was one of the great pioneers of conservation, which has made so much progress all over the world since his day.

The book is decorated with most attractive silhouette designs by Ugo Mochi; but it is marred by numerous misprints that ought to have been eliminated by competent proof-reading.

L. HARRISON MATTHEWS

Astronomical Photoelectric Photometry

Edited by Frank Bradshaw Wood. (A Symposium presented on December 31, 1951, at the Philadelphia meeting of the American Association for the Advancement of Science.) Pp. vii+141. (Washington, D.C.: American Association for the Advancement of Science; London: Bailey Bros. and Swinfen, Ltd., 1953.) 33*s*.

In his preface to this publication, consisting of eight papers submitted at a symposium presented on December 31, 1951, at the Philadelphia meeting of the American Association for the Advancement of Science, the editor states that it is the intention of the volume to provide a summary of use to those actively at work in this field and yet provide guidance to astronomers embarking for the first time on a programme of photoelectric observations.

The first paper, on the topic of direct-current techniques, contains a valuable bibliography, the references including most of the important papers from the days of pre-multiplier photometry up to recent years.

The second paper, dealing with alternating-current techniques and sources of error in photoelectric stellar photometry, suffers in its first few pages from a lack of lucidity. The portions dealing with sources of error are the more interesting features of this communication.

Pulse-counting techniques are represented by two papers, one containing a detailed description of the photometer at the Cook observatory and the other the recent developments in Great Britain carried out at Cambridge by Redman and Yates.

A recent photoelectric installation at the Observatoire de Haute Provence is described in two papers by Lallemand and Lenouvel.

A photometer constructed by Walraven combines the advantage of the null method with the excellent properties of the phototube, the arrangement in effect constituting a servomechanism.

The final paper in this attractively produced little book is by Whitford and concerns a consideration of ultimate limits and a critical summary.

A. H. Jarrett

Organic Peroxides

Their Chemistry, Decomposition, and Role in Polymerization. By Arthur V. Tobolsky and Robert B. Mesrobian. Pp. x+198. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1954.) 5.74 dollars.

This excellent little book provides a general account of the chemistry of organic peroxides with special reference to their role in initiating polymerization reactions.

The first of the three sections of the volume gives a systematic and well-documented outline of the chemistry of the various classes of organic peroxides and hydroperoxides. In the second section the manner of decomposition of peroxides under various conditions is discussed. The formation of free radicals and the diagnostic tests which may be used to detect their formation are given special consideration. Other modes of decomposition such as the Haber–Weiss process and heterolytic cleavages are also included. In the final section the kinetics of polymerization of substances of the vinyl type, such as styrene and methyl methacrylate, are described, and the methods used for determining the characteristics of the process are discussed, including the rates of initiation of polymerization and the related catalytic efficiencies of various peroxides.

The physical properties and the explosive nature of known organic peroxides are presented in tabular form as appendixes. Literature references extend to 1953 inclusive, and there are complete subject and author indexes.

This volume will provide a useful introduction to the subject which should be of real value to senior students or research workers.

G. M. Bennett

A Textbook of Sound

Being an Account of the Physics of Vibrations with special reference to Recent Theoretical and Technical Developments. By Dr. A. B. Wood. Third (revised) edition. Pp. xvi+610. (London: G. Bell and Sons, Ltd., 1955.) 42*s*. net.

To treat in one text-book both classical and modern acoustics has now become impossible. Beranek needs more than nine hundred pages to deal with acoustical measurements alone. Electro-acoustics, communication theory, ultrasonics, speech, physiological acoustics, architectural acoustics and musical acoustics each need separate volumes. Dr. A. B. Wood resolves the difficulty by continuing to present a standard treatment of classical acoustics. New diagrams, new references and fifty more pages of letterpress are added to the second edition.

The point of view is still that of classical acoustics, with its emphasis on those features of vibrating systems which can be treated by simple mathematical or experimental techniques, that is, on the steady state. Yet, as soon as speech, music or noise reaches a steady state, it ceases to be speech, music or noise.

Phenomena contrary to the ideas of classical acoustics are apt to be treated with caution. For example, in 1924 Harvey Fletcher, using electric filters, showed that if several of the lowest components of a complex sound were removed, the pitch of the sound was unchanged. Referring to this effect in this 1955 edition, Dr. Wood still writes, "He [Harvey Fletcher] claims to have proved that only the quality and not the pitch . . . is changed". The student would be helped by the addition of a short annotated bibliography of the many excellent books on acoustics published during the past ten years and also by notes on such journals as *Acoustica* and the *Journal of the Acoustical Society of America*, especially as the latter journal publishes in each number a very comprehensive list of references to contemporary papers on acoustics.

W. H. George

Call of the River

By Mabel E. Byrt. Pp. 127+8 plates. (London: Country Life, Ltd., 1955.) 8*s*. 6*d*. net.

The "Call of the River" is a story of wild life, of otters in particular, on waterway and seashore. The tale is well told, the adventures of the otters making good reading in the tradition of that great master of Nature fiction, Ernest Thompson Seton, though unfortunately the standard of accuracy is not quite so high as that of the Canadian writer. Here and there the author slips—for example, the dramatic fight of the otter with the giant conger eel. This is staged in the river, regardless of the conger eel being a marine fish not in the habit of entering fresh water. Yet by and large the book gives a vivid picture of wild life on our English rivers and in particular of that remarkable mammal, the otter. The illustrations are from photographs, and the excellent coloured jacket is from a painting by Michael Lyne.

F. P.

PERKIN AND THE DYESTUFFS INDUSTRY IN BRITAIN

By R. BRIGHTMAN

Recently Division Bibliographer, sometime Chief Librarian of the Dyestuffs Division,
Imperial Chemical Industries, Ltd.

THE centenary of the discovery of mauve may be celebrated variously from the Easter vacation of 1856 when W. H. Perkin, at the age of eighteen, accidentally made the discovery while working in the rough laboratory he had fitted up in his home at "King David's Fort", King David's Lane, Shadwell; from the date of the reply he received, on June 12, 1856, from the firm of Pullar, of Perth, to whom he sent specimens of his dyed silk, reporting the discovery as "decidedly one of the most valuable that has come out for a very long time" (provided it did not make the goods too expensive); or from August 26 of the same year, the date of the first patent application for a synthetic dyestuff. Any of these dates will serve, though the last comes nearest to giving the true measure of Perkin's achievement. None of them, however, fully represents Perkin's claim to remembrance as the founder of the synthetic dyestuffs industry, and the Perkin centenary which really deserves commemoration is not his fortuitous discovery of the dyestuff but the opening of the works which, in June 1857, he began to build for its manufacture at Greenford Green, near Sudbury. Six months later mauve, or aniline purple, was in use at Bethnal Green in the silk dyehouse of Thomas Keith and Sons, which was the first firm to use it on an industrial scale.

The story of this achievement has often been told, not always, however, with full justice to the magnitude of the achievement of a young chemist who had not even seen the inside of a chemical works and whose knowledge was derived entirely from books. Moreover, at that time very limited supplies of benzene were available, as there was little use for it, nor was the fuming nitric acid thought to be essential in making nitrobenzene obtainable commercially, and only in 1854 had Béchamp found that on a laboratory scale nitrobenzene could be reduced to aniline by means of finely divided iron and acetic acid. Without this discovery, as Perkin himself said in his Hofmann Memorial Lecture[1], the coal-tar colour industry could not have been started. The successful manufacture of aniline from nitrobenzene appeared to be so formidable a task that attention was first directed to the possibility of extracting by acid washing the minute quantity of aniline contained in coal-tar, and only after many experiments was this source abandoned as too expensive and yielding too impure a product. Such difficulties might well have deterred a far more experienced man than Perkin, whose venture, moreover, was undertaken in the face of strong discouragement from Hofmann, in whose laboratory at the Royal College of Chemistry Perkin had been working, and whose comment on the desirability of synthesizing quinine (made in the *Reports of the Royal College of Chemistry* for 1849) probably prompted Perkin's experiment, as indeed he admitted in his Hofmann Memorial Lecture. Perkin tells how, in October 1856, following visits to Pullar at Perth and experiments on cotton dyeing and on calico printing, which in the absence of suitable mordants were less encouraging than he had hoped, he sought an interview with Hofmann and told him of the discovery, showing him also the dyed patterns and announcing his intention of leaving the Royal College of Chemistry to undertake its manufacture. Hofmann appeared to be much disturbed and spoke as if Perkin was taking a false step which might ruin his future prospects.

None the less, young Perkin had faith in his results; but there has been little inquiry into the reasons which in 1856 made Perkin so confident of the importance of his discovery and so resolute to embark on its manufacture in the face of powerful discouragement and formidable technical difficulties. Dr. C. J. T. Cronshaw truly remarked in his Jubilee Memorial Lecture to the Society of Chemical Industry: "If a Faery Godmother had given Perkin the chance of choosing the precise moment for his discovery, he could not have selected a more appropriate or auspicious time"[2]. It is hard to believe that a youth of eighteen could fully apprehend the opportunities which the expanding textile industries alone offered to the new colouring matters that were to come out of coal tar in the next two decades, but justice cannot be done to his achievement unless we look a little more closely not merely at the way in which the discovery was made and brought to technical fruition by Perkin himself, but also at the scientific and technical and commercial background of the time.

At the time Perkin made his discovery, he was a research assistant to Hofmann in Hofmann's laboratory at the Royal College of Chemistry, to which Perkin had been promoted in 1854 and where he had completed his first investigation, on anthracene, at the age of seventeen. We may note, in passing, that the crude material for this research was obtained from the tar works of that Bethell whose discovery in 1838 of the value of tar for creosoting timber, coupled with the railway boom, had opened up one of the first considerable markets for coal tar and taken us a step towards the beginning of organic chemical industry. Perkin's object on this occasion was to prepare an amino-compound through the nitro-compound, and although he failed to obtain the latter, he prepared what were later recognized to be anthraquinone and chloro- and bromo-anthraquinones, and gained experience of great value when later he began work on the production of anthracene.

It is worth while looking a little further at the Royal College of Chemistry, which Perkin entered in October 1853, on leaving the City of London School at the age of fifteen, for part of Perkin's fortune consisted in the availability of such an institution for teaching and research in chemistry. True, as Perkin tells us, at the age of twelve or thirteen he had been greatly attracted to chemistry, with its possibilities of making new discoveries, by some chemical experiments shown him by a friend, particularly by the power of crystallization in definite forms possessed by some compounds. He determined, if possible, to become a chemist, and immediately commenced to accumulate bottles of chemicals and to make experiments.

Perkin's father was disappointed at William's choice of a career, as the outlook for chemistry was very poor in those days, but eventually he was allowed to follow his bent and to enter the College founded only eight years earlier. There was at this time, it is true, seldom any desire among students to become chemists, but it is not solely because of Perkin that Mr. W. A. Silvester[3] described the Royal College of Chemistry as the seed plot of the dyestuffs industry; and the circumstances in which the College was founded little more than ten years before Perkin made his discovery deserve attention. It could not well have been created at that time without the support of some strong popular feeling.

In this second quarter of the nineteenth century, organic chemistry was still little known or studied in Great Britain; as Liebig said at the Liverpool meeting of the British Association in 1837, it was only beginning to take root. Moreover, here and elsewhere the idea that chemistry should be taught and learnt in the laboratory was still new. Strommeyer had begun to admit students to his laboratory at Göttingen for practical instruction in chemistry in the first decade of the nineteenth century, but Thomas Thomson, then reader in chemistry in the University of Glasgow, in the next decade opened his laboratory to students[4] and, according to Lord Kelvin, himself in 1834 one of Thomson's students, this became the first laboratory in the world in which was carried out chemical research and the practical instruction of university students in chemistry. There were indeed other chairs of chemistry in Britain—that at Aberdeen was founded in 1793 and one at Cambridge had been created in 1702, while Daubeny had been professor of chemistry at Oxford since 1822.

None the less, the chair and laboratory at Glasgow are to be remembered here first because Thomson and Graham, who came to the Andersonian Institution, Glasgow, as professor of chemistry in 1830, spread the idea that laboratories were necessary in training chemists and, second, for the part which Graham and his students took in founding the Royal College of Chemistry, where Perkin and others who played so conspicuous a part in the development of the early dyestuffs industry were trained. No longer had students of chemistry or physics without independent means to rely for experimental work on such private bodies as the London Institution or the Manchester Royal Institution. For many years those with the means to do so flocked to the famous laboratory which Liebig opened at Giessen in 1826, or, after 1836, to that of Wohler at Göttingen. With the opening of the Royal College of Chemistry in 1845 there was in Great Britain also public provision for the practice of experimental chemistry.

The impulse to scientific and technical education had thus been given when Perkin entered the Royal College of Chemistry: Playfair's report on industrial education on the Continent had been published in 1853 and Herbert Spencer's articles on the need for scientific education began to appear in 1854. We have still to examine, however, the circumstances in which that College was founded. Among Graham's students during the seven years before he went to London as professor of chemistry in the newly founded University College were Lyon Playfair and James Young, both of whom followed Graham to London. Lyon Playfair, after two years as Graham's private assistant in 1839, on Graham's advice went to Giessen to study under Liebig, and there he first met Hofmann, at that time studying mathematics and physics. Playfair's friendship with Liebig led to him acting as conductor and interpreter when in 1842 Liebig made his famous tour of Britain. The immediate effect of this tour was to make chemistry a popular science and to strengthen the hands of those like Graham who were seeking to develop laboratory teaching. The School of Mines, which was opened in Jermyn Street, and King's College, London, as well as University College, gave much attention to laboratory teaching. Following an unsuccessful attempt to found a Davy College of Practical Chemistry within the Royal Institution, the efforts of Sir James Clark, the Queen's physician, and the Prince Consort, led to the founding of a new College of Chemistry, to which A. W. Hofmann was invited as director.

The College opened with temporary laboratories in George Street, Hanover Square, in October 1845, but by October 1846 was installed in new buildings fronting on Oxford Street under the title of the Royal College of Chemistry. When the College, in 1853, was incorporated with the new School of Mines and of Science Applied to the Arts, founded in 1851, Lyon Playfair, professor of chemistry in the latter, retired in favour of Hofmann. In the laboratories of this institution Hofmann, in the two decades 1845–65, laid an enduring mark on technical education in Britain and provided the emergent chemical industry with many of its leaders in the second half of the nineteenth century. His first batch of twenty-six students in 1845 included E. C. Nicholson, F. A. Abel, Warren de la Rue, G. Simpson and C. W. Bloxam, the second batch C. B. Mansfield, F. Field and George Merck, while among Hofmann's assistants besides students such as E. C. Nicholson, J. Spiller and W. H. Perkin himself were H. Medlock, Peter Griess and C. A. Martius. C. Simpson, like W. Spiller, E. Nicholson and G. Maule, were all partners at some time or other in Simpson, Maule and Nicholson or Brooke, Simpson and Spiller. H. T. Lowe, another student of 1848, was works manager to the former firm, F. Field, chemist to the same firm, and J. Spiller, consulting chemist. Among students preceding Perkin there were also W. Odling, W. Crooks, G. D. Liveing, while after him came W. A. Tilden and, just as Hofmann left for Berlin, W. Thorp and H. E. Armstrong.

These names alone give some measure of the influence of Hofmann and his students upon the chemical thought and industry of the time, but the picture is still incomplete. Not only did young Perkin enter the doors of the Royal College of Chemistry in the first flush of the development of practical laboratory work in Britain and when the impulse which the Great Exhibition of 1851 had given to technical education was still felt; he entered an institution where teaching and research were proceeding side by side under an inspiring leader who was rapidly writing new chapters in organic chemistry. The way was being prepared for the age of organic synthesis, and young Perkin's enthusiasm for research is better understood when we recall the exciting developments of the time as Laurent converted Dumas's theory into a real theory of substitution, Wurtz, Hofmann, Williamson and Odling elaborated the theory of types, Frankland, working on radicals, introduced the doctrine of valency, and in 1858 Kekulé and Couper independently and simultaneously advanced a satisfactory theory of molecular constitution resting on the quadrivalency of carbon and the capacity of carbon atoms to form chains, and that this theory in 1865 led Kekulé to his hexagonal structure for benzene.

"England is not the land of science", wrote Liebig to Berzelius in 1837; but although it is true that nowhere in the country was there for decades to come any school of organic chemistry comparable with that which Baeyer established at Munich, many of the important contributions of the period 1840–70 came from chemists working in Britain who might be seen at the regular meetings of the Chemical Society or the Royal Society, the journals of which provided the means of publication for Hofmann as well as for Perkin himself and others like Griess. Moreover, in the relatively small circle of chemists (even in 1856 the Chemical Society had only 256 Fellows) in which these developments took place, many were known to each other and moved as easily from London to Giessen or Gottingen or Heidelberg as from Glasgow to London or Manchester or Liverpool or Edinburgh.

The Chemical Society had only been founded in 1841 and its *Journal* did not appear regularly until 1848, but by the time Perkin entered the Royal College of Chemistry it had won its place as a medium of communication, not least for the work which Hofmann and his school were carrying out on the ammonium bases and the compounds of coal tar. The importance of this early work of Hofmann, Mansfield, Medlock and Nicholson on benzene, toluene, aniline, toluidine and alkylanilines, and especially the development by Mansfield of the technique of fractional distillation, is not easily overstressed. Without it Perkin could scarcely have attempted the manufacture of mauve and other dyestuffs for which those compounds were required.

Perhaps young Perkin was also fortunate, therefore, that in entering the one real school of organic chemistry in Britain at the time, he entered one which arose out of technology. Although Hofmann's first research at Giessen had been upon the nature of coal tar, and his paper describing this work, entitled "A Chemical Investigation of the Organic Bases contained in Coal-Tar Naphtha", was published in the *Philosophical Magazine* in 1844, coal tar was still largely a waste product and something of a nuisance when Hofmann came to London. Apart from the developing use of creosote for preserving timber, it was still frequently mixed with ashes and used to heat the retorts of the gasworks or the stills in which young Read Holliday was distilling ammonia from the ammoniacal liquor of the gasworks.

Garden had isolated naphthalene from coal tar in 1819, but it was for some time regarded as doubtful whether naphthalene existed as such in the tar or was a product of its decomposition. Mansfield, in his paper on coal tar in the *Journal of the Chemical Society* in 1847, remarking on the deposition from the tar of the London gas works of naphthalene as granular crystalline masses, called 'salts' by the workmen, states that it was thrown away as useless or burned for lamp-black, although priced at 4–5*s.* an ounce in chemical catalogues. Faraday discovered benzene in oil gas residues and described it to the Royal Society in June 1825 and suspected its presence in coal tar, and in 1832 Dumas and Laurent discovered anthracene in residues from the distillation of coal. Two years later Runge indicated the potentialities of coal tar for the organic chemist, isolating carbolic acid, or phenol, pyrrole, kyanol or aniline and leucol or quinoline, none of which he analysed; and besides noting the blue coloration developed on oxidation of aniline with bleaching powder, he also described an aniline black, emeraldine as well as rosolic acid, while according to B. Anft[6] he had discovered purpurin in 1822 and obtained a Prussian patent in 1823.

These hints, however, were not taken until first Hofmann began to investigate aniline and quinoline, and then Perkin tried to oxidize aniline. Runge appears to have had some real appreciation of the possibilities, but was frustrated by E. E. Cochius, the business manager of the Oranienburg Chemical Works, where Runge was employed, from developing them and left the firm in 1852. Thus it was that practically all the aniline used by Hofmann in his numerous inquiries until Perkin's discovery stimulated its manufacture was obtained by distilling indigo with potash.

At the meeting of the British Association in Manchester in 1842, Leigh produced evidence of the presence of benzene in naphtha; and this was confirmed by Hofmann in 1845, who had already, in 1843, in a joint paper with Dumas, shown that aniline could be obtained from phenol through ammonium phenoxide. Hofmann now induced Mansfield to investigate the liquid hydrocarbons of coal tar. Mansfield succeeded in obtaining pure benzene and toluene sufficiently pure for Hofmann and Muspratt to prepare toluidine from it, while Hofmann described ethylaniline, diethylaniline, and methylaniline in the *Journal of the Chemical Society* before Perkin entered the Royal College of Chemistry.

None the less, when aniline was required for the manufacture of mauve, several inquiries were necessary before a supplier of benzene could be found. Perkin's first supplies came from Miller and Co., of Glasgow, at 5*s.* per gallon; but this benzene was crude, very variable in quality and required redistillation. Nitrobenzene had only lately been made in small quantities as 'essence de myrbane' for scenting soap and had never been made in iron vessels. Unable to obtain commercially nitric acid which was sufficiently strong for the nitration, Perkin used a mixture of sodium nitrate and sulphuric acid. The method succeeded on a small scale, but many precautions were necessary when working with larger quantities. In the early stages, the nitration was carried out in large glass 'boltheads'. Cast iron stills with mechanical stirring gear were not introduced for some time after the manufacture of mauve commenced, and this improvement is attributed to E. C. Nicholson at the Lockfields works of Simpson, Maule and Nicholson.

Perkin himself made large quantities of nitrobenzene in this way and deserves full credit for overcoming on his own the immense difficulties that confronted him. None the less, an infant chemical industry was already developing, of which the firm of Simpson, Maule and Nicholson, established at Lockfields in 1853 as manufacturers of fine chemicals, was only one representative. Although the firm failed to obtain the desired licence from Perkin and Sons for the manufacture of mauve, Simpson, Maule and Nicholson sought to manufacture nitrobenzene for use by Perkin and Sons, and eventually did so cheaply enough to make it worth while for Perkin to discontinue the manufacture of nitrobenzene, and later of aniline also. Originally, at Lockfields as at

Greenford Green, the nitrobenzene was reduced in iron vessels with removable still-heads which were only placed in position when the reaction showed signs of starting, and a water-hose was played on the still if the reaction became too violent. It was soon found that the cheaper hydrochloric acid could replace acetic acid, and by degrees Simpson, Maule and Nicholson became manufacturers of dyestuffs. Beginning with a product, roseine, which David Price had obtained and patented in 1859, they followed this with the manufacture of magenta, which they were the first British firm to make by the arsenic process of Medlock and Nicholson. In 1860 they built the Atlas works at Hackney Wick, and on Nicholson's retirement in 1868 the firm became Brooke, Simpson and Spiller.

Perkin, however, had given the impulse, and the manufacture of magenta (the formation of which was first observed by Natanson in 1856, about the same time that Perkin discovered mauve) was attended by nothing like the difficulties which beset Perkin. Moreover, while Perkin had first, or at least simultaneously, to work out the preparation of his intermediates, his rivals largely worked from intermediates to dyestuffs, Ivan Levinstein at Blackley a little later being possibly the exception. Thus, the improvements in the manufacture of phenol for which Dr. Crace-Calvert, who had succeeded Lyon Playfair as professor of chemistry at the Manchester Royal Institution, and C. Lowe had introduced from 1857, had prepared the way both for the manufacture of picric acid, which had come into use as a dyestuff about 1851, and of rosolic acid or aurin.

Indeed, Manchester was already the centre of a small synthetic dyestuffs industry when Perkin made his discovery of mauve. Roberts, Dale and Co., for example, had begun the manufacture of inorganic pigments and dyewood extracts at Cornbrook in 1852 and their interest in wallpaper colouring made them quick to exploit every opportunity of meeting the demands of an expanding market. Besides picric acid, Roberts, Dale and Co. introduced some of the first basic and azo dyestuffs, notably aniline yellow and Manchester brown, and they had in their service for a time such chemists as Caro, Martius and Leonhardt, while Peter Griess was a consultant. According to J. B. Cohen, at one time the firm bought from Perkin and Sons the mauve residues, specially purified them, and sold the product to calico printers, who used it as a pigment, fixing it on the fibre with albumen. In Manchester also was centred the manufacture of murexide, the derivative of alloxan, the use of which in dyeing wool had been described by Schlumberger in September 1853, and which was freely marketed for dyeing silk and wool in 1856.

There are two features about the existence of this infant dyestuffs industry in Manchester which deserve notice. First, while there was a large and expanding market for the new wares in the surrounding counties of Lancashire and Yorkshire, the real impulse to their introduction came from the French dyers, from whom also came much of the demand for an increasingly purer grade of phenol during the decade 1857–66 which stimulated the work of Crace-Calvert and Lowe. It may well also have encouraged Ivan Levinstein to make his venture at Blackley in 1864, and it certainly facilitated Read Holliday's entry into the dyestuffs field; from distilling coal tar and supplying primary materials, he began to make the intermediates, and, commencing with magenta in 1860, then the colours themselves. Read Holliday was also helped by Mansfield, who at the time of his accidental death was working with hydrocarbons supplied by Read Holliday and Sons and had for the last five years of his life been experimenting for them on the utilization of benzene and toluene.

Perkin, however, had not only to make his dyestuff and, at first at least, the nitrobenzene and aniline required for its production. Its purification called for equal resource, and it may be mentioned that he had considerable difficulty in getting perfectly tight joints for the process of extracting the crude oxidation product under pressure with naphtha or strong spirits of salt. Perkin had further to find satisfactory methods of applying the mauve to fabrics and also to induce the dyers to use them. Pullar wrote to him, in the letter of June 12, 1856, already quoted: "This colour is one which has been very much wanted in all classes of goods, and could not be obtained fast on silk, and only at great expense on cotton yarns. I enclose a pattern of the best lilac we have on cotton—it is dyed by only one house in the United Kingdom, but even this is not quite fast and does not stand the tests that yours does, and fades by exposure to air". When, with the assistance of his elder brother, T. D. Perkin, he had prepared a few ounces of mauve, Perkin visited Pullar's and made some experiments on cotton dyeing, only obtaining, however, pale direct shades, not fast to washing, as no suitable mordants for a basic dye were known at that time. Experiments on calico printing were also made at some print works; but printers feared that the dye would be too dear and, although it proved to be one of the most serviceable colours as regards fastness, they were not satisfied because it did not resist bleaching powder like madder purple. Perkin then found that application with casein gave good results, but the printers who tried it were not enthusiastic and even Pullars began to waver. In January 1857, however, on Mr. Pullar's advice, Perkin saw Thomas Keith, a silk dyer of Bethnal Green, and after making a few experiments Keith encouraged Perkin to proceed with the production of mauve.

Thomas Keith and Sons were the first firm to use aniline purple on an industrial scale, and it was in use in their silk dyehouse in December 1857, only six months after the building of the works at Greenford Green was commenced. In dyeing large amounts of silk, however, the great affinity of the dyestuff led to uneven shades, and Perkin himself found that level shades could be obtained by dyeing in a soap bath. He was thus the first to introduce this general method of dyeing in a soap bath, and independently of R. Pullar he also discovered the general method of dyeing basic dyes on cotton mordanted with insoluble inorganic compounds of tannin. This method, in which cotton was steeped in a decoction of sumac or other tannin, then in a solution of sodium stannate (or alum), next in acidified water and finally dyed with aniline purple, was universally employed in preparing cotton for dyeing with basic dyes until the use of tannin and tartar emetic was discovered by John Dale, son of the founder of Roberts, Dale and Co., in 1861 and introduced by Thomas Brooks, of Manchester. Calvert claims, indeed, that he and Lowe succeeded in fixing aniline and orchil colours with tannin and alumina as early as 1858 and that they observed the precipitating action of tannins for coal tar colours in 1856. Others, such as Greatrix of Butterworth and Brookes, were also working with gall-nuts and stannous oxide or alumina, and it is clear that, if Perkin led here, it was not by much.

It was not, however, until the end of 1858, when the French printers had already introduced mauve into their patterns, that British printers began to be interested in the colour. Perkin, however, was not satisfied with the simple method by which mauve was originally used with casein, albumin or glue, followed by steaming, and worked for some time on this problem at the Dalmonach Print Works, Alexandria, Dumbartonshire, where mauve was first used in Britain for printing on the large scale. With Matthew Grey, he devised and patented a process for printing with a lead salt, passing through an alkaline solution of soap, followed by dyeing in a boiling soap bath. This gave good results, but could only be used for a single colour pattern; printers then experimented with tannin and a metallic oxide, which became the most important method until, in 1862, Perkin and A. Schultz discovered and patented a process based on the formation of an insoluble aluminium arsenite of mauve. This process could be used in multicolour patterns, gave brilliant shades fast to washing and was very largely used.

Perkin not only thus largely pioneered the application of the colouring matter, he also originated the dyemaker's practice of supplying the user with technical service. He spent some weeks in Bradford showing the dyers how to dye mixed fabrics of cotton and wool successfully with mauve, and his pioneer work in this direction cleared the way for the later introduction of magenta, Hofmann's violet and other colours also. It was not only in the manufacture of the aniline dyestuffs that Perkin started the ball rolling: he was as much a pioneer in the application of the colours. As H. E. Armstrong remarked: "Almost everything he did was novel, and he was right in nearly everything"[6].

Mauve itself had a comparatively short run, and the range of dyestuffs manufactured at Greenford Green was never extensive. At the International Exhibition in London in 1862, Perkin and Sons staged an exhibit of the varied uses of mauve and displayed a metallic glistening block of the dyestuffs representing the quantity obtainable from 2,000 tons of coal tar and sufficient to print 100 miles of calico. The following year it was used by Thomas de la Rue as an insoluble lake in printing the British sixpenny postage stamp; but within ten years from the outset, use of mauve was very limited and one of its last uses was in printing the 1881 issue of lilac British penny postage stamps which continued in use until the end of Queen Victoria's reign. Perkin's other major achievement—the synthesis and manufacture of alizarin—belongs to the last few years of the firm's existence: the first invoice for the artificial alizarin was dated October 4, 1869, in which year the firm made one ton of paste. In 1870, when they made 40 tons, the firm was still practically the only maker, and in the following three years they made 220 tons, 300 tons and 435 tons of paste with practically no opposition in the home market.

In the preceding ten years, however, Perkin and Sons had manufactured magenta by the mercury nitrate process (quickly discontinued), an ethyl derivative of mauve known as dahlia, for dyeing and calico printing; aniline pink, or safranine, obtained by oxidizing mauve with lead peroxide; the Britannia violets, discovered by Perkin in 1863 and obtained by heating purchased magenta with brominated turpentine in methyl alcohol under pressure; and Perkin's green obtained from these with acetyl chloride (a process which necessitated the manufacture of both phosphorus trichloride and acetyl chloride), used in calico printing in place of the expensive iodine green[7]. The firm also made mixtures of aniline salts, oxidizing agents, and copper compounds for use in producing aniline black.

Thus, Perkin's contribution to the development of the industry is not in the range of dyestuffs which he actually manufactured but in his demonstration of its possibilities and the resource and determination with which he overcame the initial obstacles alike to the manufacture of mauve and to its application in dyeing. To appreciate fully the magnitude of his achievement it is necessary to compare the range of colours available for the dyer's palette when he began his work with that available some five years later, when Hofmann reported as juror on the Chemical Section of the International Exhibition in London, and also to notice the way in which his ideas pervaded the scientific and technical circles of the time. By and large, the dyer used logwood for black and navy shades, indigo for blue, madder for red, yellow berries for yellow, tumeric for brown, cochineal and safflower, indigo and madder being by far the most important, though according to a report written at the time of the Great Exhibition of 1851, which puts the exports of cotton, linen, silk and leather manufactures as more than £45,000,000, imports of cochineal had increased by more than 50 per cent by weight between 1847 and 1850, and by 1851 cochineal and lac dyes had quite superseded kermes. In this report, synthetic dyestuffs are not mentioned, although Guignot showed specimens dyed with picric acid at the Exhibition. Even two years later, J. Napier's "Manual of the Art of Dyeing" contains no mention of picric acid, and yellows on silk were obtained solely with weld, bark and fustic or bark and annotta liquid. Even O'Neill's "A Dictionary of Calico Printing and Dyeing" in 1862 says of picric acid, "This is only lately introduced as a dyeing material for silks and woollens", but he reports that abundance of murexide was coming into the market along with a process of applying it on calico.

Hofmann in this juror's report quotes from an article of August 24, 1862, by M. E. Meunier: "Notwithstanding the enormous price at which the aniline colours have been sold, the new industry has already exercised a most depressing influence on the commerce of cochineal. From 15 francs 50 centimes per kg. the price of cochineal has fallen to 8 francs. Safflower is difficult to dispose of at 25 francs per kg. although two years ago easily sold at 45 francs. The production of picric acid has considerably diminished the importation of yellow dyewoods. Even indigo itself, although still occupying the first rank as a colouring matter, has been thrown somewhat into the shade by the brilliancy of the aniline blues and violets. For dyeing silk, indigo is no longer used. Thus, of three dyeing materials, hitherto considered indestructible elements of the commercial prosperity of tropical countries, we find indigo diminished in its applications, and cochineal and safflower very notably depreciated, solely and exclusively by the work of the chemist".

It did not then perhaps appear as fully as to us to-day how largely that was due to the work of one young chemist, still only twenty-two, but in England at least the natural dyestuffs retained a strong place in the dyeing and printing trades for more than a generation. Not for a decade was Perkin's production of synthetic alizarin to bring about the rapid displacement of madder. and the replacement of natural indigo by the synthetic product waited on the investment of more than £1,000,000 in research and thirty years of sustained endeavour, and added £3,000,000 to the annual turnover of the dyestuffs industry. Griess had made the observation which led him to his great discovery of the diazo compounds before he left Kolbe's laboratory in Marburg, and the note in which he first directed attention to this new reaction of nitrous acid was communicated to the Royal Society on December 8, 1858, by Hofmann, whose assistant he had then become. Aniline yellow came in 1863 and Manchester brown in 1864; but the flood gates were only opened to the azo dyestuffs by Roussin, Witt and Bottiger from 1875, after Perkin had left the industry.

It was in this juror's report that Hofmann made the prophecy: "England will, beyond question, at no distant day, become herself the greatest colour-producing country in the world, nay, by the strangest of revolutions, she may, ere long, send her coal-derived blue to indigo-growing India, her tar-distilled crimson to cochineal-producing Mexico and her fossil substitutes for quercitron and safflower to China, Japan and other countries where these articles are now derived". Even when Perkin left the industry this prophecy was not impossible of fulfilment. Perkin had shown the way: together with Hofmann and Nicholson he had largely made the industry. Hofmann's students and assistants were everywhere. Moreover, the little scientific and technical society of the time was mobile, and competition did not check a real interchange of ideas in opening up a new field in which science and technology advanced side by side.

C. H. Greville Williams, the discoverer in 1859 (1856 is sometimes claimed, but the evidence is doubtful: the discovery was patented in 1859) of quinoline blue, was a chemist with Perkin at Greenford Green during 1863–68 before founding the firm of Williams, Thomas and Dower at Brentford, where Witt a little later made some of the first acid azo dyes. F. Field, who gave his name to Field's yellow, or aminoazobenzene, which he made for Simpson, Maule and Nicholson, by passing nitrous gases from nitric acid and starch into aniline, had been previously professor of chemistry at the London Institution; Crace-Calvert in Manchester had a foot in industry as well as in teaching as professor of chemistry at the Manchester Royal Institution; Lyon Playfair, his predecessor, too, was manager of Thomson's print works at Clitheroe in 1841.

What seems worth noting in this connexion with the founding of the dyestuffs industry is the extent to which, in the meetings of the Royal Society, the Chemical Society or the Manchester Literary and Philosophical Society in the period from 1840, there was to be found a nucleus of members with industrial experience as well as a keen interest in the rapidly advancing science of chemistry. At the meetings of the Chemical Society might be found besides Graham, its first president and one of the only two British chemists for whom, in 1837, Liebig had a good word, Anderson, Lyon Playfair, W. Odling, Williamson, Kolbe, who in 1847 was assisting Playfair in London, Frankland, H. E. Schunck, and, in 1853, Kekulé, then assistant to Stenhouse at the Mint. The Royal Society numbered among its Fellows Edmund Potter, James Thomson, Walter Crum and John Mercer, men of mark in calico-printing, and also to be found in the Manchester Literary and Philosophical Society and in what are known as the Whalley meetings which began about 1843, and although the original number of ten persons was not greatly exceeded, were remarkable for the distinction of their membership.

Less than justice has been done to the influence of the Manchester Literary and Philosophical Society in the mid-Victorian era in fostering the spread of ideas and the interaction of science and technology. Early in its history Thomas and William Henry were well known for their contributions in developing dyeing and calico-printing, and that tradition was carried on in the 'forties and 'fifties by John Dale and by H. E. Schunck, originally a calico printer, who in 1842 characterized the organic colouring matters to the Chemical Society as an "unexplored field" and became one of the earliest workers in it, particularly on indigo and madder, his investigations providing Pincoff and Co., of Manchester, with the basis for the improvements in the manufacture of alizarin and garancin which Hofmann commended at the 1862 Exhibition. Co-worker with Schunck on alizarin at Rochdale until 1850 was James Higgin, another Fellow of the Chemical Society and an authority on calico-printing, who also worked for a time with Dr. Angus Smith and later, in 1857, with John Lightfoot had a patent application for fixing colouring matters with glue or glutinous or aluminous substances. John Mercer himself had retired from his partnership in Fort's calico-printing works at Oakenshaw eight years before Perkin's discovery of mauve, and the versatile James Young had, in 1847, after eight years in Manchester, in which he founded the first chemical section of the Literary and Philosophical Society, been started off by Playfair on the quest which founded the Scottish shale oil industry. Before he left Manchester in 1852, by bringing together in this Chemical Section in informal discussions, usually around the tea table, some thirty works chemists, he widened the opportunities for discussion between industrialists and scientists, then essentially amateurs, already notable in and around Manchester.

It does not detract from the merit of Perkin's real achievements that there is strong evidence that the hint given in Runge's work twenty years earlier was not altogether lost on the chemists of the north, and that if Perkin had not lighted on mauve others in Lancashire would soon have produced aniline red or similar products by oxidizing aniline bases.

In spite, however, of the evidence of the close relations between science and industry at that time, we find H. E. Roscoe, in 1883, more than a quarter of a century later, expressing the hope that "calico-printers ere long will buy dyes from British dye makers". That hiatus suggests that another tendency of the time deserves note in passing, though its full effect on the dyestuffs industry was scarcely felt for another fifty years. While it is true that Hofmann himself returned to Germany in 1865 and that within a few years Caro, Martius, Leonhardt, all of whom had worked in the developing British industry, followed him to build up the industry in Germany after the Franco–Prussian war, there was another movement outward from the Royal College of Chemistry and the British firms. We have already noted the close association of academic life and industry in the person of Playfair himself and Crace-Calvert. There were others also; but, equally important, Hofmann's students and assistants moved out into academic life as well as into industry, and thus there were some places at least where the seed which Playfair and Roscoe later scattered in their campaign for technical education fell on fertile ground.

So, though within ten years of Perkin leaving the industry, drawn by his passion for research, the decline of the industry in Britain was being lamented by Roscoe, Levinstein and others, the seeds of its future expansion were already being scattered. But we are not here concerned with why they lay dormant for over a generation or the reasons which led to the industry languishing to its near extinction, or with its brilliant renaissance in the past forty years, but to commemorate Perkin's achievement, with Hofmann and Nicholson, in founding an industry.

That Perkin was fortunate in his hour and in his times is undeniable, but the chance which placed mauve in his hands was the chance which favours the prepared mind. There was nothing haphazard or half-hearted about the way in which Perkin equipped himself for the career of research on which his mind was set, and, through those sixteen years which he spent in the industry which he, more than anyone else, created, he displayed the same determination, enthusiasm and pioneering spirit that he brought to bear in his laboratory during a long life of research. He could claim, with complete justification in lecturing to the Society of Arts in 1868: "to introduce a new coal tar colour after mauve was a comparatively simple matter. The difficulties of all the raw materials had been overcome as well as the obstacles". It was not his luck but his initiative, his resourcefulness, his persistence and determination that made him the foremost technologist of his day, and the qualities and achievements which constitute Perkin's real claim to remembrance in industry are exactly those which are still needed as Britain faces the social and industrial implications of an age in which coal will no longer form the sole basis of power or of technology.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH*

ANNUAL REPORT FOR 1954–55

Research Associations

DURING the year 1954–55 grants were offered to three new research organizations, bringing the total of those in receipt of grant from the Department of Scientific and Industrial Research to thirty-nine, with six other co-operative industrial research organizations which have not yet reached the status of research associations. Co-operative industrial research for the glass industry has been carried out at the Department of Glass Technology, University of Sheffield, since 1915; but while this Department will continue its long-term fundamental research, the work of more direct industrial interest will be undertaken by the new Association, to which a block grant of £10,000 a year has been offered for the period April 1, 1955–March 31, 1960, conditional on £20,000 being obtained from industry, and with up to an additional £12,000 on a cent-per-cent basis from industry. The Research and Development Committee of the Timber Development Association, which has acquired new premises near High Wycombe, has been offered a block grant of £14,000 a year for the period January 1, 1955–December 31, 1957, conditional on £28,000 coming from industry, with up to a further £4,000 on the cent-per-cent basis.

New terms of grant were offered to eight research associations and research councils during the year. The British Leather Manufacturers Research Association, for the period October 1, 1954–September 30, 1956, will receive a block grant of £16,000 a year, conditional on £32,000 coming from industry, with up to a further £12,000 on a cent-per-cent basis. From October 1, 1956, to September 30, 1959, the block grant will be conditional on the Association receiving £34,000 from industry. A special programme of research on the dyeing and pigment-finishing of leather has been commenced, and trials on goatskins in India through the monsoon indicate that sodium pentachlorophenate is effective in keeping sound skins in a good condition. Long-term investigations of the particle size of chromium complexes in solution indicate that the average size increases with the basicity of chrome tanning liquors. A method has been found by which soft and extensible leather backing can be made to adhere to glacé kid skins, and comprehensive washing trials have shown that while soap is harmless to chamois washing leathers, anionic detergents containing polyphosphates, as well as non-ionic detergents, are liable to cause damage.

The Cutlery Research Council, which for the period January 1, 1952–December 31, 1959, will receive a block grant of £3,000 a year, conditional on £4,000 coming from industry, and up to a further £3,000 on the cent-per-cent basis, continued its long-range project on the properties and heat treatment of cutlery stainless steel. In accordance with the change in emphasis to longer-term work of a more fundamental nature, projects have been initiated on the quality and characteristics of cutlery edges and a study of mechanical polishing processes and the surface finishes they produce. For the period January 1, 1955–December 31, 1959, the block grant to the Parsons and Marine Engineering Turbine Research and Development Association will be increased to £40,000 a year, conditional on £100,000 coming from industry, with up to a further £30,000 on the basis of £75 for each additional £100 from industry. Extensive tests on an experimental high-pressure, high-temperature steam turbine operating at 1100° F. and 1,100 lb./sq. in. are revealing the relative suitability of various materials for use under these conditions. An epicyclic turning gear incorporating a hydraulically operated disk brake for engagement and an automatic overload cut-out has been developed, and great advances made in the design of new bearings which have much lower power losses, greater overload capacity, and the ability to continue running after occurrence of oil failure.

---

* Continued from p. 771.

The terms of grant to the British Internal Combustion Engine Research Association for the period April 1, 1954–March 31, 1957, are unchanged, providing a block grant of £15,000 a year conditional on £25,000 being received from industry, with an additional £10,000 on the usual basis. Further confirmation has been obtained of the accuracy of the Bicera method of evaluating crankshaft stiffness, and investigations of the running characteristics of a four-stroke cycle engine fitted with variable-ratio pistons continued, employing turbochargers of conventional type. Work on test rigs continued in order to determine the applicability to larger engines of previous findings in connexion with valve gear noise and a simplified form of pilot injection device, intended primarily for use with a hydro-pneumatically operated injection pump, has been developed.

The Motor Industry Research Association, which has completed its first year in its new laboratories at Lindley, near Nuneaton, will receive a block grant of £30,000 a year, conditional on £80,000 coming from industry, for the period July 1, 1955–June 30, 1960, with up to a further £30,000 on the basis of £75 for each additional £100 from industry. Work proceeded on a study of bending and torsional loads in the crankshafts of a 'square' petrol engine (in which the cylinder-bore and piston stroke are equal) and of a 10-litre, 6-cylinder, 4-stroke, compression-ignition engine. The effect of design features of cast crankshafts on the torsional fatigue strength was studied and also the causes of failure in service of splined axle shafts, and work initiated on torque converters included a critical survey of hydrokinetic, hydrostatic and mechanical converters and experimental investigation of a hydrostatic converter.

For the period October 1, 1956–September 30, 1960, the Linen Industry Research Association will receive a block grant of £15,000 conditional on £30,000 being received from industry, with up to an additional £10,000 on the cent-per-cent basis. In its spinning research, the Association has given priority to the development of a new servo-drafting control mechanism which permits greater regularity of yarn and the spinning of finer counts, and to a modified ring system for wet spinning which gives much greater productivity. Work on the macro-structure of the flax fibre continued and a new method of testing the water-proofness of cover canvas is being developed.

The Research Council of the British Whiting Federation, which has acquired additional premises at the Hall, Welwyn, in order to undertake pilot-plant work, will receive a block grant of £6,000 a year for the period January 1, 1956–September 30, 1959, conditional on £10,000 coming from industry, with up to an additional £2,000 on the cent-per-cent basis. The efficient use of fuel in the drying processes of the industry has been studied in the works of members and numerous recommendations made leading to appreciable economies, while work on hydraulic and air methods of classifying whiting continued. For the period January 1, 1956–December 31, 1958, the Research and Information Committee of the Furniture Development Council, since April 1955 housed under one roof in premises in Holloway, will receive a block grant of £6,000 a year, conditional on £10,000 coming from industry, with up to a further £4,000 on the basis of £80 for each additional £100 from industry. Research on cabinet construction, particularly the structure of cabinets made from wooden frames with thin panels attached, continued, the development of performance tests for domestic furniture has been completed and efforts are being made to develop simple and accurate means of assessing the properties of finishing materials, particularly lacquers.

Of the work of the remaining research associations, only a few points of interest can be mentioned here. The fundamental work of the British Baking Industries Research Association on natural oils in flour and bread indicates that the flour oil fraction considerably affects bread quality and is closely linked with the way in which bread quality is improved by shortenings and other substances. The British Boot, Shoe and Allied Trades Research Association has issued a major report on the comprehensive survey of the feet of more than two thousand adult women which introduces a new way of looking at and analysing foot measurements and may profoundly affect design of the last. The British Cast Iron Research Association has developed a promising technique for sampling molten metal for hydrogen estimation, and the British Ceramic Research Association's study of the health hazards associated with the towing of the edges of plates in the fettling process and the application of correct air-flow principles substantiated by ciné-photography in special lighting have led to the design of an exhaust hood which gives satisfactory control of the dust and is now being widely adopted by the industry. The British Coal Utilization Research Association's work on domestic appliances has shown that the central heating and hot-water supply demands of a house of medium size can be satisfactorily provided by a relatively small boiler of 6–10 sq. ft. heating surface, and in the trials two new systems of automatic control were developed and patented, utilizing the pressure differential available across the circulating pump. The British Coke Research Association has made further studies of the thermal conductivity of the coal charge during carbonization and of the properties of carbon and the process of carbonization. Extensive mill trials are proceeding of a hood and extraction system developed by the British Cotton Industry Research Association for fitting to carding engines, which, by reducing the dust content of the atmosphere by 90 per cent, is believed to reduce the accompanying disease of byssinosis. Further progress is reported of the Shirley Developments, Ltd., the activities of which are now beginning to affect appreciably the rate of application of scientific advances by the industry. The British Electrical and Allied Industries Research Association has installed an automatic equipment for cyclic tests on joints with live steam at a power station, and in experiments on polythene cross-linked by high-energy radiation has discovered a new type of intrinsic breakdown, in which the material fails mechanically under the electrostatic forces present. The British Hat and Allied Feltmakers' Research Association continued its study of damage to wool noils and a comprehensive large-scale study of the carrotting process. The Research Association of British Flour Millers continued to collaborate with the National Institute of Agricultural Botany in the effort to find wheat varieties of improved milling and baking quality, and also its work on the effect of improvers upon the quality of flour. The British

Food Manufacturing Industries Research Association extended its study of the melting and crystallizing behaviour of cocoa butter and of possible alternative fats; and the Fruit and Vegetable Canning and Quick Freezing Research Association continued its work on the effect of conditions of cutting and drying of harvested peas on their texture when canned as processed peas.

Steady progress was made by the British Gelatine and Glue Research Association in fundamental investigations into the structure, properties and mode of formation of gelatin and animal glue; and the Hosiery and Allied Trades' Research Association's investigations on crimped nylon products promise to facilitate a more precise control of their 'handle' and elastic properties. The permanent fireproofing process developed in the British Jute Trade Research Association's Laboratories retains its effectiveness even after immersion in sea water for four to five weeks and also after four months free exposure to atmospheric conditions. Further work by the British Launderers' Research Association has confirmed the effect of traces of impurities in the fibres on the extent of dirt removal produced by detergent solutions. A method recently developed in the British Non-Ferrous Metals Research Association's laboratories allows the fatigue limit of many materials to be determined in a few hours with only one specimen, and the Association has also developed the use of the direct-reading spectrograph, the quantograph, in the analysis of copper and copper alloys. The Research Association of British Paint, Colour and Varnish Manufacturers is using autoradiography to examine the migration of plasticizer from synthetic latex paint films into wooden substrates, and continued a special programme on the adhesion of paint films to their substrates.

The work of the British Paper and Board Industry Research Association is making a material contribution to scientific knowledge of the physical structure of papermaking fibres which it is hoped will lead to improved techniques for developing the physical characteristics in commercial pulp required to produce sheets of paper of satisfactory quality. A main object of the packaging research of the Printing, Packaging and Allied Trades Research Association is to improve the performance of packages so that they provide the maximum protection at the minimum cost. The British Rayon Research Association made further fundamental studies on the frictional properties of individual fibres with particular reference to the effect of diameter. The electromagnetic method of thickness-gauging devised by the British Scientific Instrument Research Association for use on lead-covered power cables has reached the stage of commercial exploitation.

The wide range of the contribution to industrial advance and to national welfare which the Department of Scientific and Industrial Research is making, both directly through its own research stations and indirectly through its support of the research associations and of fundamental research at the universities, is sufficiently illustrated by the foregoing examples. What should be no less apparent is that the real difficulty is to select from the many possible projects those on which public money can be spent to the best advantage. The increased provision made for the work of the Department over the past few years has not, in fact, permitted any real expansion: it has scarcely balanced the mounting costs of research. While the present report does not supply all the information required for a sound judgment, it does indicate the need for some careful consideration of the exact functions of the Department and of its place in the national organization of research when the Bill now before Parliament to change its administrative and financial arrangements is debated.

DETECTION AND DEVELOPMENT OF SCIENTIFIC ABILITY

On March 17, the British Social Biology Council held a conference on "Scientific Ability: its Detection and Development" at the London School of Economics. It was attended by a good number of teachers, representatives of Government departments, members of national organizations of a scientific nature, and representatives of industry. The purpose of the conference was to consider the influences acting on the minds of boys and girls in deciding whether or not to take up science; the ways in which scientific ability may be detected and developed; and the extent to which originality in science is subject to changing conditions. It brought to light three major points.

The first point was that although science is rapidly altering the material fabric of the economic world, and profoundly influencing all aspects of human culture, very little consideration is being given, at research level, to the nature of scientific ability itself and the conditions under which it develops. This is particularly true of Great Britain. Studies made in the past, chiefly in the United States, have little value in predicting scientific talent, since they fail to distinguish promise in this direction from that in other walks of human life, such as commerce, the arts and the professions. There is urgent need for new researches to be undertaken, drawing on the insights provided by recent progress in psychology.

The second point was that while latent intelligence is almost certainly inherited—a point that received no consideration at the conference—it is now fairly generally agreed that the manner in which it manifests itself is subject to influences of a personal and social nature. There does not appear to be any special mental characteristic that is essential for success in science; instead, given equal degrees of intelligence, the difference between the scientist and the artist, the teacher and the man of affairs, can be attributed to the accidents of family upbringing, educational training, and opportunities in the choice of a career. This realization carries with it a supplementary one that in varying degrees, depending on innate intelligence, there is still in the nation a large reservoir of potential scientific ability lying latent—both among boys, and to a still greater extent among girls, among whom its development presents special difficulties.

A third point was that owing to social pressures, tendencies that are recognized as being unfavourable continue in operation, on account of the absence of positive action to resist them. It was, for example, generally agreed that specialization ought not to take place in the schools until a boy or girl has reached the Ordinary level of the General Certificate of Education; but some of those present explained that they were powerless to resist the demands of parents who wanted their children to have the longest possible time in which to prepare for highly competitive examinations. Yet as a measure of attainment, the General Certificate of Education examination itself came in for criticism. At a later stage the same kind of pressures were seen to be exerting a bad effect on work done in polytechnics and similar institutions, the overcrowded syllabus leaving the students no time to pursue their own interests and investigations. These pressures will continue until a concerted effort is made to alter the character of examinations like those for the General Certificate of Education at Ordinary and Advanced level, the First M.B. and for university scholarships, so as to give less weight to the mere accumulation of knowledge that a candidate can carry in his head.

Prof. N. F. Mott opened the proceedings by emphasizing that the function of a university was to give specialized training of a high degree. He felt that in a cultural sense, breadth depended on studying some subject thoroughly and then seeing where it led. But he was aware of the dangers of excessive formalized teaching, and in favour of postponing some of it to courses leading to the Ph.D. degree. He felt compelled to recognize that, under present conditions, a certain amount of specialization at school was unavoidable.

Discussing the nature of scientific ability, Mr. Alec Rodger explained that it took a variety of different forms and that lines of demarcation were indistinct. After reviewing the studies that have been made of this problem, he thought that one might conclude that, in favourable circumstances, any reasonably able person might become a reasonably competent scientist (though he made an exception in the case of high ability amounting to genius); and since it appeared that general ability was convertible, he drew the conclusion that, in the schools, early specialization in any direction should be resisted. He put forward the suggestion that since young children are keen observers, it might be advisable to build up early training in science around some agriculture instead of the traditional chemistry and physics.

Mr. M. A. Brimer, of the National Foundation for Educational Research, also emphasized the unreliable nature of qualities which in the past had been held to be indicative of ability in science. Those that might be of value in the selection of a young scientist might prove of little reliability in assessing the capabilities of a mature research worker. Throughout the country there was no uniformity in the selection test at 11+ years of age, on the results of which children were transferred to grammar schools. The same was true of the test at 13+ years, upon which allocations were made to technical schools. He criticized the General Certificate of Education examination, which was allowed to take place without any check on its reliability; it covered a narrow range of attainment and had only a restricted scope. Basing his case on the argument that the variety of patterns of experience depended on the size of a school, he was in favour of comprehensive schools, and felt that the new ones to be built should be larger than those now in existence. Mr. Brimer suggested that in the schools guidance should be individual and continuous; he looked forward to this development as an essential part of the educational service, carried out by staff specially trained in psychometrics.

Problems relating to the teaching of girls were considered by Dr. E. M. Delf-Smith. Speaking generally, girls' schools experienced acute difficulties on account of the shortage of scientifically trained teaching staff, inadequate laboratory space and a poor supply of equipment. All this, she thought, constituted a great handicap for the nation, not only in a material sense, of girls being lost to science, but also in that conditions were allowed to continue which fostered an outlook on life that lacked a proper appreciation of the cultural value of science. She recognized that it was easier for girls to win places to universities in arts than in science, and that, as a whole, girls showed greater aptitude for biology than for physics; even so, if full use were made of their latent abilities, they would release men for work in the more technical fields, such as engineering.

For the afternoon session, Prof. R. M. Barrer was in the chair. He referred to the number of first-year men at the universities who appeared to have reached the upper limit of their capacity. They constituted a problem in selection, yet all forms of ability were needed by the nation. For success in science, however, certain personal characteristics were also essential, a point that, in his day, Faraday had appreciated.

Drawing on many years of teaching practice under school conditions, Mr. W. Llowarch, of the University of London Institute of Education, said that the most gifted young scientists that had passed through his hands had not fitted into any normal pattern of training; they had demanded individual attention. Yet a considerable proportion of them had elected to take up engineering although they had shown promise of being capable, after suitable training, of undertaking fundamental research. Teaching practice in the schools was still preoccupied with the factual and informational aspects of science, leaving too little time for independent inquiry. The good second-class boy, he thought, might have his interest aroused best if the approach were made through engineering or agriculture.

Mr. W. H. Dowdeswell, of Winchester College, said that observation and originality were the sparks that shone most brightly in a young scientist. All children were born experimenters; they rebelled against repetition and loved to pursue inquiries to which there was no known answer. Because of that, there was a wide difference in practical work between experiment and verification. He considered that for some of the most gifted boys, the last one or two terms at school, after the scholarship examination, were extremely valuable, providing the opportunity for ranging widely and pursuing individual lines of investigation. For non-scientists, he made a strong case for a course in general science at a late school stage. For similar, but still stronger, reasons he made a plea for the introduction of courses in Science Greats at the universities.

The discussion produced a convincing statement from Mr. A. J. Peters, of the National Foundation for Educational Research, on the need for more technical training. A survey on which he had been engaged had shown that the supply of pure scientists was comparatively good but that there was a serious shortage of technologists and technicians. Present school courses in chemistry and physics did not appeal to many boys willing and capable of taking up these occupations; and owing to the lack of adequate facilities, thousands of children in secondary modern schools were being lost to British industry. At the grammar school level, too, the lack of suitable equipment for training in applied science was almost universal. In suggesting that considerable scope remained for increasing the supply of young scientists, he was strongly supported by some other speakers, who considered that existing standards of requirements for entrance to industry should be critically examined and courses of training carefully reviewed.

As a whole, however, the discussion served to reveal once more the short range and empirical nature of the terms in which educational matters, and those relating specifically to training in science, are being considered not only by teachers but also by representatives of industry, members of public bodies and by many people at the universities, including a high proportion of scientists. These terms are not adequate for the effective assessment of the problems with which we are faced; still less can they be relied on to produce any satisfactory solution. A wider appreciation of the importance of fundamental research is essential, and with it must be associated a deeper understanding of the part that social forces play in the development and expression of all kinds of human ability. This is the only way in which, at this stage, the supply of scientists can be substantially increased. Only then will science take its true place in the cultural life of the nation.

OBITUARIES

Prof. W. H. Keesom

Prof. W. H. Keesom, whose death occurred in Leyden on March 3, was born on June 21, 1876, the son of a farming family at Texel, which is one of the small islands in the north of Holland. On this island the majority of the habitants make their living by lamb breeding. During many years the father of Prof. Keesom was a well-known figure on the lamb market of Leyden, which he regularly visited to deliver his lambs. His origin from the north established a strong impress on the personality of Keesom. So he was tenacious, but 'silent' and difficult in conversation. Also from his origin the young Keesom was not prepared to become a specialist in physics.. Because of his unusual intelligence, his parents sent him to Alkmaar to study there at the secondary school.

At the age of eighteen, Keesom started to study at the University of Amsterdam. There he followed the courses of van der Waals and van 't Hoff. It was under the influence of those great masters that Keesom's interest for physics appeared.

In 1900 Keesom left the University of Amsterdam and became assistant under Kamerlingh Onnes at the Physical Laboratory of the University of Leyden. There he worked for seventeen years (1900–17), first as assistant and later as conservator, under the direction of Kamerlingh Onnes on the thermodynamic properties of gases and specially of helium. In 1904 he obtained his doctorate under van der Waals at the University of Amsterdam with a thesis entitled "Isotherms of Mixtures of Oxygen and Carbon Dioxide". In 1912 there appeared his famous paper "Die Zustandsgleichung", in the "Encyclopadie der Mathematischen Wissenschaften".

Keesom left Leyden in 1917 to become lecturer and later professor in the University for Veterinary Science in Utrecht. There he developed a laboratory for X-ray analysis of the structure of solidified gases. In 1923 he returned to Leyden as successor to Kamerlingh Onnes, and since 1924 he had, with Prof. W. J. de Haas, directed the Kamerlingh Onnes Laboratory there. From that date the laboratory was divided into two sections (I and II): Keesom undertook the directorship of section I, which was specially devoted to the study of molecular physics; de Haas took for his part the field of magnetism.

After the success obtained by Kamerlingh Onnes in liquefying helium, the remaining programme consisted in making a systematic study of the physical properties of liquid helium. So Keesom started to study, with Wolfke, the dielectric constant of liquid helium. With Clusius, and later with his daughter Annie, he measured the specific heat of liquid helium. It is well known that those measurements led Keesom to the detection of the two phases of liquid helium, helium I and helium II. Just before 1926, Keesom had succeeded in solidifying helium. Also, in his attempts to obtain still lower temperatures, Keesom, together with Gaede, succeeded in 1932 in reaching a temperature of 0·7° K. by pumping off liquid helium. During his systematic study of the specific heat of metals and in particular of superconducting metals, Keesom detected with Dr. Kok the jump in the specific heat of tin.

Apart from his two famous discoveries, namely, the λ-point of liquid helium and the jump in the specific heat of superconducting metals, Keesom and his collaborators carried out a lot of important work in the field of molecular physics. Thus I may mention his systematic work on van der Waals forces by means of measurements on the equation of state, the vapour pressure curve of helium, adsorption of gases, viscosity of gases and liquid helium, the structure of condensed and solidified gases, etc.

To close his scientific career Keesom wrote his book "Helium", which contains essentially a complete report of his life-work on helium in the three states. It is also necessary to mention the important part played by Keesom in the organization of the Institut International du Froid and in the preparation for its international meetings. His various collaborators during those exciting times will remember the way in which he stimulated everybody to write their reports for those meetings. He liked to feel that the outside scientific world should be impressed by the work done at Leyden.

The Second World War stopped Keesom abruptly in his scientific work. As a consequence of the tragic events of those times, Keesom began to suffer from neurasthenia, an illness which had attacked him earlier, after the death of his first wife. He retired from the University of Leyden in 1945.

During recent years, Keesom had recovered intellectually and again found some interest in scientific problems, which he discussed with his son Piet, professor of physics in the University of Purdue, who is continuing the systematic work of his father on the specific heat of metals.

Keesom was known by his collaborators and friends as a severe but kindly director; he was always extremely helpful to young scientists and students.

A. Van Itterbeek

Brigadier J. A. Sinton, V.C., O.B.E., F.R.S.

John Alexander Sinton, who died on March 25, was born in British Columbia, of Ulster parents, on December 2, 1884. He was educated at the Royal Belfast Academical Institution and at The Queen's College, Belfast, where he was an exhibitioner. He graduated M.B., Ch.B., with first-class honours at the Royal University of Ireland in 1908, and after holding house appointments at the Royal Victoria Hospital, Belfast, became Riddell demonstrator in pathology at The Queen's University and clinical pathologist to the Ulster Eye, Throat and Ear Hospital and to the Mater Infirmorum Hospital. In 1911 he took the diploma of tropical medicine at Liverpool, and in the same year entered the Indian Medical Service.

During the First World War, Sinton served as a regimental medical officer in Mesopotamia and was awarded the Victoria Cross for most conspicuous bravery and devotion to duty during an action at Sheikh Sa'ed in 1916. He also received the Russian Order of St. George, and was mentioned in dispatches on four occasions. He was promoted brevet major in 1919 and saw further active service in Afghanistan and Waziristan, being again mentioned twice in dispatches and being appointed O.B.E. in 1921.

On reversion to civil employment in 1921, Sinton entered the Medical Research Department of the Indian Medical Service. He was in charge of the Quinine and Malaria Inquiry at Kasauli during 1921–30 and was director of the Malaria Survey of India from its foundation until 1936. He returned to England in that year, and in 1937 became Manson Fellow of the London School of Hygiene and Tropical Medicine and adviser on malaria to the Ministry of Health. He also carried out researches in the Malaria Laboratory, Horton. On the outbreak of the Second World War he was recalled to duty and, after a brief period in India, became consultant malariologist successively to the East African Forces, the Middle East Forces and the War Office. He finally retired in 1945 with the honorary rank of brigadier and settled down on a country estate at Cookstown in Northern Ireland. He took an active part in public affairs, being a justice of the peace and high sheriff for Tyrone.

Sinton's activities covered a wide field, but were principally concerned with the study of malariology in its various aspects. His researches on the chemotherapy of the disease were of outstanding importance and he also published a number of papers on its immunology, parasitology, laboratory and survey techniques and sociological effects. Among his other interests was the study of cutaneous leishmaniasis, on which he published several articles. He was also the author of a series of thirty-six papers on Indian species of *Phlebotomus*, on which he was a leading authority.

Sinton was elected a Fellow of the Royal Society in 1946 and received a number of other honours. He was awarded the Arnott Memorial Medal of the Irish Medical Schools and Graduates Association in 1917; the Chalmers Memorial Medal of the Royal Society of Tropical Medicine and Hygiene in 1928; the Bisset-Hawkins Medal of the Royal College of Physicians of London in 1944; the Robert Campbell Memorial Medal of the Ulster Medical Society in 1946; the Mary Kingsley Medal of the Liverpool School of Tropical Medicine in 1949; and the Manson Medal of the Royal Society of Tropical Medicine and Hygiene in 1956, an award which was announced only a few days before his death.

Sinton was a man of boundless energy, high moral rectitude and outstanding personal charm. He never spared himself in any of his endeavours and was a source of inspiration to all who came in contact with him. He was buried with full military honours near his home in County Tyrone.

G. Covell

Dr. A. G. Lowndes

Ashley Gordon Lowndes, who died on March 15 at Falmouth after an attack of pneumonia, has left his mark on science in several ways. His passion for investigation produced some valuable researches and, perhaps even more important, it generated in others a love of the subject and a rigour of method that have been the basis of many successful investigations. He went to sea in the Merchant Navy at the age of thirteen, until he was twenty-six, when the curate of a church in Portsmouth, where Lowndes was taking a Sunday School, recognized his brilliance as a teacher. The curate's father was the headmaster of Ardingley and he took Lowndes on to his staff. From there he went to Cambridge, where he was one of J. T. Saunders's first pupils and obtained a 'double first' and a 'swimming blue'. He joined the analytical staff of Nobel Industries as a chemist, and there his ideas led to several successful new processes.

The next phase of Lowndes's career was that Norwood took him to Marlborough as biology master, and it was here that he did his best work, both as teacher and investigator. He drove his pupils hard but gave them a real opportunity to see the fascination of living things and the possibility of exact investigation of them. It must be more than an accident that so many of them have proved to be successful investigators and teachers. His simple belief in scientific and moral principles, single-minded love of the subject and directness of statement, provided a compelling appeal to boys and an excellent basis for life.

Lowndes became interested at this time in Crustacea, and his series of papers on them are probably his best scientific work. He quickly mastered the systematics of the Entomostraca and contributed substantially to knowledge of freshwater copepods and ostracods. He would probably have been wise to concentrate on systematics, but it was characteristic of him to want to do more. By breeding experiments he showed that the superficially similar *Leptocyclops speratus* and *agilis* are unable to cross, although the various races of the latter do so freely. He then embarked on a study of locomotion and feeding, first in *Chirocephalus*, then in calanoids. He used elegant photographic techniques and obtained results that seemed to him unambiguous. But as he entered these experimental fields his aggressiveness led him into controversies of a type that often seemed unhappy; but were perhaps necessary for him. They became still more marked as he attacked more complicated problems, such as the mechanism of flagellar movement and the density of aquatic organisms. In such matters he usually had much of right on his side, but his simple approach sometimes let him down. The value of his work was recognized by the award of the Cambridge Sc.D.

He gave up his career at Marlborough to undertake research in a leper colony in West Africa, where he stayed for eighteen months. When asked why he had left he replied, "Well, it is obvious why the natives get leprosy and I told the authorities so, but they wouldn't listen to me. Since we have stopped them eating each other the only protein they get is an occasional snake".

After this he taught in a number of schools, though never with quite the same success as at Marlborough. He declared that of all the nine headmasters he had served under none could hold a candle to Norwood. He continued investigations on various biological and geological subjects, receiving much hospitality from the Marine Biological Association at Plymouth.

Lowndes carried always something of the sea about him, in his rolling gait, his simple directness and sharpness of observation. His influence will be felt by his pupils for more than one generation, and his contributions to knowledge of Crustacea may last even longer than that.

J. Z. Young

NEWS and VIEWS

Directorship of the British Scientific Instrument Research Association :

Mr. A. J. Philpot, C.B.E.

Mr. A. J. Philpot will retire in June from the directorship of the British Scientific Instrument Research Association, a post which he has held since 1937. Mr. Philpot had a distinguished academic career at King's College, London, and later, after active service in the First World War, at Cambridge in the Cavendish Laboratory under Lord Rutherford. In 1920 he joined the staff of the British Scientific Instrument Research Association soon after its foundation as the first of the co-operative industrial research associations to be established. As senior physicist of the Association he accomplished a large amount of experimental work, the results being recorded in publications and twenty-one research reports on subjects as varied as X-ray tubes, the stability of glasses, luminous compounds, thermometer liquids and the deposition by volatilization of reflecting surfaces on glass. In 1937 Mr. Philpot was appointed director of research and secretary of the Association, in succession to Dr. Harry Moore, and soon his responsibilities were greatly enlarged by the Second World War. In 1943 he was appointed chairman of the new Inter-Service Optical Instrument Committee which did vital co-ordinating work. Though the laboratories of the Association, in Russell Square, London, were damaged by a bomb, many firms new to instrument manufacture were helped to master the problems of design and production, and the end of the War found the Association with a greatly increased membership but quite inadequate laboratory space. New premises were found on the outskirts of London, new departments were established and new staff engaged, and Mr. Philpot found himself director of an organization which had multiplied its size by five in a couple of years. At the same time, he undertook new duties, being for a number of years director of the Scientific Instrument Manufacturers' Association, the trade association of the industry. Mr. Philpot has played an active part in the affairs of scientific societies concerned with physics and instruments, and has been vice-president and treasurer of the Physical Society, vice-president of the Institute of Physics, and vice-president of the Society of Instrument Technology.

Dr. J. Thomson

Dr. J. Thomson, who will succeed Mr. Philpot, is a graduate of the University of Glasgow, being awarded the Kelvin Medal of the University in 1932 for research in mathematical and experimental physics. He lectured in physics at the Universities of Reading and Glasgow until the end of 1939, when he joined the Admiralty Signal School at Portsmouth. During the Second World War he was engaged in research on microwave devices, and his work included service with a Royal Marine Commando Unit throughout the German campaign. After the War he was appointed professor of physics and electrical engineering in the Royal Naval College, Greenwich, and later he became the deputy director of physical research (C.V.D.) at the Admiralty with responsibility for research and development in the field of electronic valves on behalf of the three Armed Services. Last year he also undertook the editorship of the new *Journal of Electronics*. His published work includes three books and many research papers.

Presidency of the Society of Glass Technology :

Dr. J. H. Partridge

At the annual general meeting of the Society of Glass Technology, held in Sheffield on April 25, Dr. J. H. Partridge was elected president, in succession to Sir Graham Cunningham, who has retired after serving for two years. Dr. Partridge graduated in metallurgy from the University of Birmingham in 1924, and four years later joined the Research Laboratories of the General Electric Co., Ltd. ; he is now head of the Company's Glass, Refractories and Ceramics Department. He has published more than thirty papers on studies relating to metals, glass and refractories and is the author of "Refractory Blocks for Glass Tank Furnaces" (1933) and "Glass-to-Metal Seals" (1947). Dr. Partridge has been a vice-president of the Society of Glass Technology and was honorary general secretary during 1946–49.

New Foreign Members of the Royal Society

The following have been elected foreign members of the Royal Society : Kai Ulric Linderstrøm-Lang (Copenhagen), distinguished for his contribution to protein chemistry and for his pioneer development of ultra micro-techniques for the biochemical study of the localization of enzymes in tissue cells ; Hans Pettersson (Göteborg), distinguished for his researches in oceanography ; Robert Burns Woodward (Cambridge, U.S.A.), distinguished for his investigations in organic chemistry, especially on the synthesis of important natural products such as quinine, cortisone and antibiotics ; Fritz Zernike (Groningen), distinguished for his researches in phase-contrast microscopy.

Royal Society Delegation to Moscow

AT the invitation of the Academy of Sciences of the U.S.S.R., the Royal Society is sending a delegation to Moscow under the auspices of the Soviet Relations Committee of the British Council. The delegation will leave on May 18 and will spend a fortnight in the U.S.S.R. visiting scientific institutions. Lord Adrian, the immediate past-president of the Royal Society, will lead the delegation, and other members are: Lady Adrian; Dr. H. G. Thornton, foreign secretary of the Royal Society and head of the Department of Soil Microbiology at Rothamsted Experimental Station; Miss M. L. Cartwright, mistress of Girton College, Cambridge; Prof. J. H. Gaddum, professor of pharmacology in the University of Edinburgh; Prof. J. M. Robertson, professor of chemistry and head of the Chemical Laboratories of the University of Glasgow; Prof. M. Stacey, professor of chemistry in the University of Birmingham; and Dr. D. C. Martin, assistant secretary of the Royal Society.

Merck Institute for Therapeutic Research

THE facilities and staff of the Merck Institute for Therapeutic Research have been approximately doubled recently by the incorporation of several research groups at West Point, Pa., which were formerly part of the Sharp and Dohme Division of Merck and Co., Inc. There is now a staff of more than three hundred, sixty-five of whom hold M.D. or Ph.D. degrees. The Merck Institute, which was founded in 1933, is a separately incorporated organization of Merck and Co., Inc., its function being to investigate the biological properties of new drugs and chemicals and to conduct fundamental research in the medical and veterinary sciences. Besides its laboratories at Rahway, N.J., and West Point, Pa., it also has Branchburg Farm, a two-hundred acre experimental farm at North Branch, N.J. Dr. L. Earle Arnow, formerly vice-president and director of research of the Sharp and Dohme Division, has been appointed executive director of the Merck Institute and will direct all the activities of the various branches of the Institute. Dr. Hans Molitor, director of the Institute since its founding in 1933, has been elected chairman of the board of trustees of the Institute in succession to George W. Merck, and at the same time has been appointed director of scientific relations of the Merck Sharp and Dohme Research Laboratories, with the responsibility for the development of relations with investigators in the United States and abroad. Other appointments in the Institute are as follows: Dr. Harry J. Robinson, formerly associate director, to be director of the Rahway unit; and Dr. Karl H. Beyer, formerly head of pharmacological research at Sharp and Dohme, to be director of the West Point unit.

Statistics of Scientific Workers and Technologists in Britain

IN reply to a question in the House of Commons on April 18, the Secretary of State for Air said that about 7,500 graduate scientists and technologists of equivalent standing are employed in a civilian capacity in defence establishments in Britain, and about 3,000 men with such qualifications are doing National Service. The number of officers and men in all three Armed Services with scientific qualifications of this standard is not readily available. In reply to a further question on April 19, the Financial Secretary to the Treasury, Mr. H. Brooke, stated that it is not possible to give an estimate of the proportion of science graduates who, on leaving college, take up work in defence and civilian organizations, respectively. The only information is derived from returns by university authorities, which are not comprehensive and do not distinguish between work in defence organizations and in civilian organizations. Asked for an assurance that no part of the proposed £100 million savings in government expenditure would be made at the expense of technological education, Mr. Brooke said that the Government attaches the highest importance to increasing the numbers of scientific and technological graduates from the universities.

In a written answer on April 13, the Chancellor of the Exchequer gave the number of university students taking first degrees and diplomas in pure science during 1954–55 as 5,304. Of these, 2,226 were pass degrees and diplomas, and 558 general honours degrees; honours degrees in mathematics were 504; in biological sciences, 380; chemistry, 917; physics, 597; and in geology and related sciences, 122. For technology, the figures were: pass degrees and diplomas, 1,912; honours degrees in civil engineering and building, 215; chemical technology, 123; mechanical and aeronautical engineering, 191; electrical engineering and electronics, 158; mining, 52; metallurgical engineering and metallurgy, 114; general engineering, 364; other technologies, 36; and architecture, 56.

National Reference Library Plans

THE Chancellor of the Exchequer was questioned again in the House of Commons on April 24 about the funds he proposed to make available for the establishment of a National Reference Library of Science and a Lending Library. Mr. Macmillan said in reply that he is making £2,500 available during the current year for the purchase and binding of scientific periodicals as a beginning to the Lending Library, and that £10,350 has been included in the estimates for the purchase of books and periodicals for the Patent Office Library. This Library will eventually form the basis for the National Reference Library, but Mr. Macmillan declined to add anything to Mr. Bevin's statement on November 1 as regards capital expenditure. The proposals of the Advisory Council on Scientific Policy are still being considered. In a written answer on April 20, the cost of the new National Library in Bloomsbury was estimated as about £10 million.

Scientific Research in British Universities, 1954–55

THE Department of Scientific and Industrial Research has prepared a volume, "Scientific Research in British Universities, 1954–55", which provides brief notes indicating the scientific research in progress in British universities and university colleges during the academic year 1954–55 (pp. 572. London: H.M.S.O., 1955; 12*s.* 6*d.* net or 2.25 dollars). The material has been collected by the British Council from the heads of departments of the university institutions concerned and is issued by the Department of Scientific and Industrial Research with the agreement of the Agricultural and Medical Research Councils. Entries are limited to permanent members of the staff normally engaged in supervising research.

As in previous issues, entries are arranged alphabetically first by universities, and then under the university by departments. There are a name list and an alphabetical subject index to research programmes. Although some major institutions have supplied no information, this is a formidable volume running to nearly six hundred pages.

Nuclear Engineering

The Temple Press is to be congratulated on the high quality of the first number of its new publication, *Nuclear Engineering* (1, No. 1; April 1956; 3*s.* 6*d.* per copy, annual subscription 42*s.*). This journal should appeal not only to qualified engineers engaged in the design of nuclear reactors, but also to those interested in the uses of radioactive isotopes, or in the instrumentation associated with these two topics. Of the fourteen articles, five give details of particular reactors, one outlines the Central Electricity Authority's plans for the generation of electrical power by nuclear fuel, two deal with the production, transport and disposal of radioactive isotopes, and one with instrumentation. The remaining articles discuss the training of nuclear engineers, the Harwell Reactor School, the structure of the United Kingdom Atomic Energy Authority and the development of glandless pumps. The final article is "An Introduction to Nuclear Energy". An interesting section of this journal, and one which will be a regular feature, includes editorial comments, news items, both from home and from abroad, of interest to those connected with nuclear engineering, trade events and developments, and personalia. There are also abstracts of technical papers and a section dealing with processes and equipment, both of which should assist many who find difficulty in keeping abreast of the very rapid development of this field. Advertisements from nearly one hundred advertisers show the very large part that industry is now playing in the development of nuclear energy in Britain. Finally, the Temple Press shows its awareness of the necessity for training nuclear engineers to a high standard by its announcement of a postgraduate scholarship, tenable at any British university, for studies directed towards the engineering aspects of nuclear energy.

New Form of *Science Abstracts*

COMMENCING with the January issues (Vol. 59), both *Physics Abstracts* and *Electrical Engineering Abstracts*, Sections *A* and *B*, respectively, of *Science Abstracts*, appear in a completely new form. The page size has been increased to 11 in. × 8½ in., and the text is printed by photolithography from typewritten material, the whole of the typing and mounting being done in the office of *Science Abstracts*. The adoption of this new method has long been contemplated, not only because of the increasing cost of good letterpress printing, but also because it is technically better suited to the production of a periodical like *Science Abstracts* than the orthodox methods of printing. The abstracts are typed and corrected for press, arranged in order for the monthly issue and the papers made-up by pasting the abstracts into position. Once the pages have been photographed, no further proof-reading is necessary. Fresh items can be included up to a very late stage in the process. This method, which is not possible with ordinary metal-type printing, saves considerable time, and it is hoped, also, that there will eventually be considerable advantage in the publication of the annual indexes, by the development of new methods of assembling and reproducing the entries. Though the new form cannot equal the standard of good letterpress printing, by the use of semi-automatic electric typewriters a high standard of appearance, clarity and legibility is achieved. The increased page-size allows a longer line to be used. Apart from the increased page size and the new method of printing, no other change has been made in the preparation of the abstracts, and the contents, classification and indexing follow the accustomed pattern. Each abstract is given its appropriate Universal Decimal Classification number and headed by the English title of the article, the authors' names and the location of the article, together with a statement of the language, if foreign. The length of the article is also indicated.

Daedalus: a Journal of the American Academy of Arts and Sciences

THE journal which in the future will appear under the title of *Daedalus* (86, No. 1; 1955) is, in fact, the continuation of the *Proceedings of the American Academy of Arts and Sciences*, the volume serial numbers of the *Proceedings* being continued. The charter of incorporation granted to the American Academy of Arts and Sciences by the Massachusetts Legislature in 1780 summarized the purpose of the Academy as being "to cultivate every art and science which may tend to advance the interest, honor, dignity, and happiness of a free, independent, and virtuous people". The new *Daedalus* does not aim at popularization, but it hopes to attract the interest of all classes of scholars. In the experimental stages, it will appear at irregular intervals, with not less than two issues in each calendar year, but eventually it is hoped that regular quarterly numbers may become possible. The present number includes articles on Daedalus; a catalogue of *H* (II) Regions in the Milky Way; physical problems of photosynthesis; Count Rumford on photosynthesis; publishing the papers of great men; and art as the function of an audience.

Centre International d'Epistémologie génétique

As a result of a grant from the Rockefeller Foundation, the Centre International d'Epistémologie génétique was recently established in the Faculty of Science, University of Geneva, under the direction of Prof. Jean Piaget. The Centre, which was opened on October 1, 1955, is an interdisciplinary one, and is closely asssociated with the Department of Psychology, University of Geneva. It consists of a team of research workers (from the logico-mathematical, natural and psychological sciences) interested in the experimental and theoretical study of developmental behaviour. Its members are L. Apostel (logic and axiomatization in behavioural science), B. Inhelder (child development), B. Mandelbrot (language, decision theory and information theory), W. Mays (logical machines and cybernetic models), A. Morf (research on mental development of logical reasoning), J. Piaget (genetic psychology) and J. Rutschmann (genetical evolution of perception and physiological mechanisms). The general topic of study for the present year is the relation between logical structures and the behaviour and thought of the subject in his development. A guest symposium on this topic will be held in July next, when the first publication of the Centre will also appear. Inquiries and correspondence should be addressed to the acting secretary, Mlle. S. Taponier, Centre International d'Epistémologie génétique, Geneva 14.

Science Museum Classified Lists of Historical Events

A VALUABLE new series of inexpensive pamphlets, under the general title of "Classified Lists of Historical Events", has been issued by the Science Museum, London, the first being on "Mechanical and Electrical Engineering, including Energy Conversion, Transmission and Storage; Atomic Energy; Pumping, Blowing and Compressing Machinery; Explosives and Ordnance", compiled by G. F. Westcott (pp. 40. London: H.M.S.O., 1955; 2*s*. net). The lists contain the dates of the principal scientific discoveries and their authors, from the earliest times to the present day. The references are naturally very much fuller for the past hundred years than for earlier ones. The compiler has had to contend with a most difficult problem of selection and classification, and it would be only too easy to disagree with the items chosen for mention or omission in a particular list. It is satisfactory that experimental and development work is not allowed to take entire precedence over analytical and theoretical work, and it is also good to see that, for the most part, the events noted are the successful applications rather than the suggestions that never came to commercial fruition. The compiler requests ideas for improvement, and one such suggestion is that two indexes should be added: a name index and a subject index, giving against each entry the dates on which the person or object is mentioned. This would be a great asset to the use of these lists; it would not be too formidable to compile, and would not require alteration in subsequent editions.

New Germanium Phototransistor

THE introduction by Mullard, Ltd., of a germanium phototransistor, type *OCP*71, which is similar in form to a conventional low-power junction transistor, opens up new possibilities for compact, inexpensive, light-operated devices. The phototransistor is sufficiently sensitive to operate a relay of normal type directly. It is of the *p–n–p* alloy type, and for most applications the base is left floating so that only two connexions to the phototransistor are required. The dark current at 25° C. is less than 300 μamp., while the light current, for a sensitive area of 7 sq. mm., can be of the order of 4 m.amp. The spectral response ranges from the visible into the infra-red region, with a peak at 1·55μ and a cut-off at 2μ. The phototransistor is not suitable for use above 40° C., and the optical cut-off frequency (that is, the maximum frequency of response when the light source is chopped or otherwise interrupted) is in the region of 3 kc./s. The overall size, including the glass envelope, is 15 mm., and its small size, together with its low voltage operation and other characteristics, make it particularly suitable for tape and punched-card reading in addition to most industrial control applications such as photoelectric counters, speed measurement, liquid-level controls, edge detection in paper-making and textiles, etc., and burglar alarms.

Oil in the Karroo Series, South Africa

COMMERCIAL oil developments in the Union of South Africa have often been mooted in the past, especially in the Karroo rocks; but it has hitherto proved to be misguided optimism. Memoir 45 of the Geological Survey (pp. 130. Pretoria: Department of Mines, 1953; 10*s*.), which has only recently been received, gives results of a comprehensive field-examination of oil possibilities in this series. The conclusion is reached that results rule out the areas mapped as likely sources of petroleum. The main evidence of possible occurrence of oil in southern Karroo is the presence of 'pseudocoal', a solid product apparently derived from hydrocarbon distillation at a temperature not more than 400° C., found in joints and veins in sediments. But pseudocoal is as elusive a surface indication as crude oil is itself in the Union. When it is categorically stated that "it is hoped that the present description of the results obtained by the State will discourage future waste of private money and energy that could be diverted to more profitable uses", then it would appear that the swan-song of Karroo oil has at long last been realized.

Latex of Apocynaceae

A COMPREHENSIVE study has been made by J. van Die of some aspects of latex-particle formation in species of the order Apocynaceae (*Ann. Bogorienses*, 2, 1, 1–214; 1955). The latex-coagulate, comprising all the particulate matter in a latex, has been analysed in some forty species of about twenty-five genera. Like latex-coagulates in general, these latices have been found to contain only a few types of compounds, these being closely related chemogenetically, such as the polyisoprene hydrocarbons (rubber and gutta), triterpenes and fatty acids, which all appear to be built up enzymically from acetate carbon via acetoacetate. Little is known about the origin of cinnamic acid, which is found occasionally in latex-coagulates. Since the particles may represent some 40–90 per cent of the constituents of dry latex, it is inferred that their formation is quantitatively one of the most important functions of the latex cell. The composition of the coagulate varies little from one part of a plant to another, and this is also true for the average degree of polymerization of the polyisoprene. Only *cis*-polyisoprene (rubber) has been found in the plants examined. The acetone-soluble substances of the latex-coagulates have been analysed by column chromatography. They consist in all cases of triterpenyl esters and triterpenols. Digitonin-precipitable compounds were never found, so that phytosterols form less than 1–2 per cent of the unsaponifiable substances present. From the analyses it is concluded that acetate carbon is the precursor of the particles. They are built up by the particle-forming centres into polyisoprene, triterpenols and fatty acids. In some cases, latex-particle compositions can serve as an indication of the systematic relationships of species and forms which are difficult to distinguish morphologically (for example, *Plumiera*), but, generally speaking, they cannot be used for tracing connexions between individual genera.

National Research Council, Canada: Members

THE following have been appointed new members of the National Research Council, Canada, for three years from April 1: Prof. I. McT. Cowan, professor and head of the Department of Zoology, University of British Columbia, Vancouver; Prof. J. H. L. Johnstone, head of the Department of Physics and dean of the Faculty of Graduate Studies, Dalhousie University, Halifax; Prof. R. B. Miller, professor of zoology in the University of Alberta, Edmonton; and Prof. B. W. Sargent, professor and head of the Department of Physics, Queen's University, Kingston. Two other members have been reappointed for a further term of three years: Prof. R. F. Farquharson, professor and head of the Department of Medicine, University of Toronto; and Dr. David L. Thomson, vice-principal of McGill University, Montreal.

Oversea Service Division, Colonial Office

THE following appointments have recently been made in the Oversea Service Division, Colonial Office: J. Cook (chief field officer, Federation of Malaya), director of agriculture, Sarawak; V. E. Gale (senior agricultural officer, Western Region, Nigeria), principal agricultural officer, Western Region, Nigeria; J. R. G. Hadland (principal cocoa officer, Western Region, Nigeria), assistant director (cocoa), Western Region, Nigeria; J. O. Torto (food production commissioner, Gold Coast), deputy director of agriculture, Gold Coast; H. Vine (senior specialist officer, Federation of Nigeria), principal research officer (soils), Western Region, Nigeria; D. F. Davidson (senior assistant conservator of forests, Cyprus), conservator of forests, Cyprus; J. A. D. Jackson (assistant conservator of forests, Northern Region, Nigeria), senior assistant conservator of forests, Northern Region, Nigeria; J. C. K. Mashall and F. S. Walker (conservators of forests, grade B, Federation of Malaya), conservators of forests, grade A, Federation of Malaya); H. G. Burks (metallurgist, Tanganyika), chief research officer, Geological Survey, Tanganyika; A. R. Melville (senior research officer, Kenya), chief research officer, Agricultural Department, Kenya; J. M. Waterston (research adviser, Federation of Nigeria), director of agricultural research, Federation of Nigeria; M. J. Fitzpatrick (veterinary investigation officer, Northern Region, Nigeria), principal veterinary officer (research), Northern Region, Nigeria; R. D. Fotheringham (livestock officer, Northern Rhodesia), dairy and poultry officer, Northern Rhodesia; E. P. Rice (assistant director of veterinary services, Kenya), deputy director of veterinary services, Kenya; A. Angus, plant pathologist, Northern Rhodesia; M. Bigger, entomologist, Tanganyika; R. A. Fitton, agricultural officer, Gold Coast; W. A. Hope, specialist assistant, Northern Region, Nigeria; S. B. Boaler, assistant conservator of forests, Somaliland Protectorate; G. H. Brister, assistant conservator of forests, Kenya; S. H. Inchbold-Stevens, assistant conservator of forests, Trinidad; U. L. S. Murthy, assistant conservator of forests, Sarawak; E. J. G. Swellengrebel and A. T. Vink, assistant conservators of forests, British Guiana; W. W. Bishop, pleistocene geologist, Uganda; R. Bradshaw, specialist adviser (petrologist/geologist), British Guiana; J. Brazell, director, East African Meteorological Department, East Africa High Commission; J. F. McCloy, senior scientific officer, East African Industrial Research Organization; E. B. Halpin, veterinary officer, Northern Region, Nigeria.

Announcements

PROF. D. KEILIN, lately Quick professor of biology and director of the Molteno Institute, University of Cambridge, has received the degree of doctor of medicine *honoris causa* of the State University of Utrecht, on the occasion of the 320th anniversary celebrations of the University.

DR. R. N. BRACEWELL, formerly of the Division of Radiophysics, Commonwealth Scientific and Industrial Research Organization, Australia, has joined the Radio Propagation Laboratory of Stanford University, California, as associate professor of electrical engineering; with support from the United States Air Force Office of Scientific Research, he is planning to obtain daily spectroheliograms at 9 cm. wave-length using a Mills cross-aerial with a cone of reception of 10^{-6} stereradians.

THE fourth meeting of the General Fisheries Council for the Mediterranean will be held in Istanbul, during September 17–22. The member countries of the Council are Egypt France, Great Britain, Greece, Israel, Italy, Monaco, Spain, Tunisia, Turkey and Yugoslavia, but other countries and international organizations can send observers. Those who wish to submit papers should write before May 15 to the Secretary, General Fisheries Council of the Mediterranean, Food and Agriculture Organization, Viale delle Terme di Caracalla, Rome.

THE Institute of Physics, in conjunction with the British Nuclear Energy Conference, has arranged a conference on "The Physics of Nuclear Reactors", to be held in London during July 3–6. The proceedings of the conference will be published as a supplement to the *British Journal of Applied Physics*. An allotment of places (without payment of conference fee) has been made to members of the other constituent bodies of the British Nuclear Energy Conference, namely, the Institutions of Civil, Mechanical, Electrical and Chemical Engineers. Application forms for the conference and further information can be obtained from the Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

As part of the summer programme of the Massachusetts Institute of Technology, arranged by Prof. Ernest H. Huntress, director of the Institute's Summer Session, a number of short courses will be held by the various Departments as follows: June 18–29, modern food technology; June 25–July 6, aerodynamic heating of aircraft structures in high-speed flight; August 6–17, orbital and satellite vehicles in space flight; August 13–17, analogue-digital conversion techniques; August 20–31, tropical hurricanes; August 20–31, modern communication theory; August 20–31, molecular engineering. Application forms for these courses and further information can be obtained from the Summer Session Office, Room 7-103, Massachusetts Institute of Technology, Cambridge 39, Mass.

THE French National School for Geographical Sciences will hold a course during June 4–July 13 on the theory and practice of aerial photogrammetry. The course, like those of previous years, is designed for non-French students wanting to familiarize themselves with instruments and methods currently used in France. Lectures will be delivered in French, with explanations in English and Spanish for those not fluent in the French language. The fee for the course is 20,000 francs. Application should be made by May 15 to the Director, École National des Sciences Géographiques, 2 Avenue Pasteur, Saint-Mandé (Seine), from whom further information can be obtained.

THE proceedings of a symposium on cell secretion which took place in March 1955 at the Institute of Biology of the University of Minas Gerais, S. Paulo, have now been published. The volume has been edited by G. Schreiber, and inquiries for it should be sent to him at the Instituto de Biologia, Faculdade de Filosofia, Universidade de Minas Gerais, Belo Horizonte, Brazil.

NATIONAL SCIENCE FOUNDATION, WASHINGTON, D.C.

REPORT FOR 1954–55

THE fifth annual report of the National Science Foundation, Washington, D.C.*, covering the year ended June 30, 1955, includes a brief review of the operation of the Foundation during its first quinquennium, but otherwise follows the pattern of the fourth report. The report of the director, Dr. A. T. Waterman, is in two parts: the first discusses some current aspects of American science, such as the loyalty and security considerations which determine the Foundation's grants for non-classified scientific research; the forthcoming International Geophysical Year, synthetic rubber research and development and the indirect costs of research supported by Federal grant or contract at educational institutions; the second reviews the work of the Foundation itself during the year. A foreword by Chester I. Barnard emphasizes the importance of leadership by the Federal Government not only in the financial sphere, but also in developing an adequate supply of scientists if science is to make its full contribution to the public welfare. Such leadership rather than direction is the Government's function, and the need for co-ordination can be met best by fostering the collection of facts regarding all aspects of the scientific situation and facilitating communication between scientists and scientific institutions. Appendixes occupying almost half the report list the personnel of the Foundation's Board and its advisory panels and committees, the basic research grants and fellowships awarded during the year, publications of the Foundation and the financial report.

During the year ended June 30, 1955, the Foundation made 588 grants, totalling 7,857,395 dollars, to 184 institutions for the support of basic research in the natural sciences. Of these, 275 (totalling 3,542,495 dollars) were in the biological and medical sciences and 313 in the mathematical, physical and engineering sciences. During the period 1952–55 the Foundation has made 1,232 grants totalling 14,316,140 dollars in support of basic research in the natural sciences, and the present report stresses the special efforts of the Foundation to foster co-operative research with nuclear emulsions (for which purpose a second conference was sponsored at De Pauw University on March 30, 1955), research on the solid state, on high-speed computation and in geochemistry. Grants have been made for the assistance of biological field stations, and a limited programme of support of the social sciences was approved in August 1954. The programme is being administered within the framework of the Foundation's three scientific divisions, using the criteria of science (that is, the identification, within the social disciplines, of those areas characterized by the application of the methods and logic of science), national interest, convergence of the natural sciences and social sciences, and basic research. The Foundation has also established a continuing programme for providing funds to medical schools for research stipends to medical students.

In March 1955 the Foundation announced the award of 715 fellowships and 70 post-doctoral fellowships for advanced study in the natural sciences for the year 1955–56. Of these, 225 were in the biological sciences, 183 in chemistry, 108 in engineering, 31 in the terrestrial sciences, 63 in mathematics and 175 in physics and astronomy. A research programme on techniques for fellowship selection over the past three years has led to some modifications and simplifications in the methods used in selecting. Three further conferences on the role of physics in engineering education were held during the year under review, dealing with mechanics, with thermodynamics and with electricity and magnetism. The Foundation continued to sponsor a series of summer institutes for science teachers and instituted a survey of the educational and vocational attitudes of high-school leavers in an attempt to discover why talented youths often fail to continue education. The survey was able to arrive at an estimate of the numbers of those who wished to proceed to college but would be prevented from doing so.

The Foundation is also extending its interest in the exchange of scientific information and is urging scientific societies to seek some permanent solution of their publishing difficulties and to undertake studies that will lead to a clearer understanding of the facts and problems of scientific publication. The Foundation is supporting the publication by the Science Division of the Library of Congress of comprehensive lists of United States and Russian scientific serial publications as well as a list of the world's biological serial publications, and also a study in the Technical Information Division of the Library of Congress to determine the extent to which information first available in unclassified government reports is afterwards published. Funds have been provided for bringing up to date the indexes for *Biological Abstracts* and for a thorough study of biological abstracting, and the Foundation is also attempting to promote fundamental research on methods of organizing information and on the feasibility of translation by machines. Continuing support was given to the translation and publication of an English edition of the Russian *Journal of Experimental and Theoretical Physics* and to the Scientific Translations Centre of the Library of Congress, and 132 scientists were given grants enabling them to attend twenty-nine different international scientific meetings.

Including those already noted, the National Science Foundation sponsored, alone or jointly with other bodies, twenty-one conferences convened during the year to examine special areas of science, chiefly where adequate support was not available from industrial or other sources. They included an international symposium on problems relating to arid lands, sponsored jointly with the American Association for the Advancement of Science, the United Nations Educational, Scientific and Cultural Organization, and the University of New Mexico; conferences on the crust of the Earth, the anomalous magnetization of rocks, man's role in changing the face of the Earth, the cosmic distance scale, and on genetic, psychological and hormonal factors in the regulation of patterns of sexual behaviour in mammals; mathematical tables; research in the history, philosophy and sociology of science, the mechanics of sediment transport, radiocarbon dating, the evolution of behaviour, the theory of numbers, mathematical statistics and probability, problems of nuclear structure, molecular quantum mechanics and high-energy nuclear physics; the twentieth Cold Spring Harbor Symposium on Quantitative Biology, at which special emphasis was given on population genetics; and the fourteenth Growth Symposium of the Society for the Study of Development and Growth. Some 137 scientists from the United States and abroad were assisted to attend the Garden Research Conferences.

---

* National Science Foundation. Fifth Annual Report for the Fiscal Year ending June 30, 1955. Pp. 159 + ix plates. (Washington, D.C.: Government Printing Office, 1955.) 50 cents.

Appropriations for services and equipment for the International Geophysical Year totalled 1,914,957 dollars, and during the next fiscal year the Foundation plans to make a full evaluation of current basic research activities on synthetic rubber, the average annual expenditure on contract research, which at universities and other institutions during the quinquennium ending June 30, 1955, exceeded 1,118,000 dollars and at the government laboratory at Akron 1,094,000 dollars. The Foundation assumed responsibility on July 1, 1955, for administering the Federal programme for basic research on synthetic rubber. At the request of the Bureau of the Budget the Foundation has also given special attention to the indirect costs of research supported by Federal grant or contract at educational institutions and has recommended procedure for reimbursing such indirect costs where requested. Adoption of the policy is estimated to involve an additional cost to the Federal Government of not more than 8 million dollars, or 2·3 per cent of the present Federal expenditure on research in such institutions. As regards the loyalty and security considerations in making grants for non-classified scientific research, Dr. Waterman affirms that the Foundation will not knowingly support anyone who is, by admission or conviction, disloyal to the United States; its grants will be made on the judgment of outstanding scientists in his field and of persons possessing personal knowledge of his competence and integrity.

RESEARCH IN SEMICONDUCTORS

SYMPOSIUM AT OTTAWA

A SYMPOSIUM on semiconductors took place during February 13–14 at the National Research Council Laboratories, Ottawa, at the invitation of the Low Temperature and Solid State Physics Group of the Division of Pure Physics; the arrangements followed the lines of the symposium on melting reported in *Nature* of January 7. The chairmen were Dr. D. K. C. MacDonald and Dr. W. B. Lewis.

When opening the meeting, Dr. MacDonald said that the subject of semiconductors was chosen because of widespread interest throughout Canadian universities and laboratories. The Low Temperature and Solid State Physics Group is specifically interested in bulk properties, and is investigating magnetic susceptibility and the thermal and electrical conductivities, as well as the occurrence of semiconductivity in intermetallic compounds; but the scope of the meeting in general would be much wider. Later, Dr. Lewis said that quite apart from the revolution it has effected in electronics, research in semiconductors may well provide a basis for a new statistical treatment of processes whereby energy is stored and dispersed. In nuclear reactors, energy is produced initially in a very intense form, and dispersed under conditions far from thermal equilibrium. The processes of dispersal and degradation of this energy, until it emerges as heat, seem to require a statistical approach which would be essentially different from the traditional equilibrium theories of thermodynamics and thermal fluctuations, and yet would to some extent take their place.

In the first of two papers, R. E. Burgess (University of British Columbia) outlined the theory of statistical fluctuations of both the spatial and temporal distributions of electrons among the energy-bands and -levels in a semiconductor; these give rise to 'patch' effects and noise, respectively, and the theory can be compared with experiment. In his second paper, mathematical analysis of the characteristics of germanium point-contact diodes (showing voltage turnover) was shown to lead to severe restrictions on conjectural models: possible mechanisms were discussed, and in particular a model due originally to Gunn appeared to be consistent with these restrictions.

W. B. Pearson (National Research Council, Ottawa) described briefly the concept of the semiconducting valence bond, which has proved fruitful both in accounting for known semiconductors and in predicting new ones, and went on to discuss further aspects of bonding in semiconductors. G. F. Bolling and J. W. Rutter (University of Toronto) showed how both the grain structure and the distribution of impurities in solid germanium are affected by the way in which it is formed from the melt. This is important both for obtaining distributions required for electronic devices and for knowing how to avoid the formation of undesirable substructures in the solid. J. Sharma (National Research Council, Ottawa) described an experimental frequency analysis of the glow peaks obtained at different temperatures from luminescent alkali halides. The luminescence is caused by colour centres, and a provisional model was put forward to account for the spectra caused by different types of centre. Two chemists, D. M. J. Compton and T. C. Waddington (National Research Council, Ottawa), described experiments on the organic semiconductor anthracene, with various kinds of electrode, various impurities and under various conditions of illumination. Among properties measured have been the electrical conductivity, Hall effect and distribution of space-charge. Marked differences in behaviour from typical inorganic semiconductors require correspondingly different explanations.

Other papers were given by J. H. Simpson (National Research Council, Ottawa) on the calculation of the ground-state of an *F*-centre; by J. Rolfe (National Research Council, Ottawa) on the design of high-frequency transistors; by Z. Szepesi (Canadian Marconi Co.) on the similarity in electrical characteristics between condensed layers and single crystals of cadmium sulphide; by F. T. Hedgcock (National Research Council, Ottawa) on the magnetic properties of very dilute germanium alloys down to 8° K.; by R. P. Singh (National Research Council, Ottawa) on the functions developed by Wannier for use in the theory of a perturbed lattice; and by A. O. Barut (University of Montreal) on the conditions needed for a rigorous quantum statistical derivation of thermodynamics.

An informal report of the proceedings is being prepared, similar to that produced for the previous symposium on melting and diffusion.

T. H. K. Barron

TAYLOR, TAYLOR AND HOBSON, LTD., LEICESTER

SEVENTIETH ANNIVERSARY

THE firm of Taylor, Taylor and Hobson, Ltd., which has long enjoyed an international reputation in the field of photographic and engineering optics and in precision testing and gauging, celebrated the seventieth anniversary of its founding on April 12 by inviting some ninety guests, representing government departments, research and trade associations, learned bodies, and suppliers to and customers of the firm, to attend a lunch at the Grand Hotel, Leicester, and to visit its works to view an exhibition representative of its range of products and to see demonstrated the processes of their manufacture, assembly and testing. At the luncheon, Mr. Mark H. Taylor, the managing director, gave a brief account of the history and work of the firm, some personalities associated with it and its relations with its customers. Other speakers were Mr. H. P. Potts, president of the Machine Tool Trades Association, Mr. A. J. Philpot, director of the British Scientific Instrument Research Association, and Sir William Palmer, vice-chairman of Rank Precision Industries, Ltd., of which organization Taylor, Taylor and Hobson, Ltd., is now a constituent company.

The visit to the works was designed to give a cross-section of the manifold activities of the firm at the present time, which afford a fine example of the ramifications that can result quite logically from developments of an initially limited field of activity. The firm was started in 1886 when the brothers T. S. and W. Taylor, both products of the Finsbury Technical College (now the Northampton Polytechnic, London), set up in business in Leicester; the former had been apprenticed to R. and J. Beck, Ltd., and the latter trained as an electrical engineer, and they described themselves as "Engineers and Manufacturers of Optical, Electrical and Scientific Instruments". Their principal activity was the making of high-quality lenses of conventional type. Shortly afterwards they were joined by W. S. Hobson, who concerned himself principally with sales.

For the first few years it would seem that little more was achieved than a reputation for fine workmanship (an interesting exhibit was what is presumed to be the first balance sheet showing each of the two brothers as having assets of approximately £240 after the first year of trading), and it was the securing in 1893 of the sole rights of manufacture of the famous Cooke photographic lens which really launched the firm on its successful course. It placed the company (it became a private limited company in 1901) in the forefront of the photographic optical industry, and this, of course, has been one of its most important activities ever since. Photography in the 1890's meant little more than portrait and landscape photography and a limited number of specialized processes; but the present century has seen many highly specialized needs created, and Taylor, Taylor and Hobson have played a leading part in meeting many of them. Cinematography called for large-aperture short-focus lenses of very high quality. Sound films demanded even faster lenses, as noisy arc-lamps had to be replaced by the photographically less satisfactory incandescent lamps, and the company's 'Speed Panchro' *F*/2 lens already developed by it met this need immediately. The 'Technicolor' process, requiring simultaneous registration of three colours by one lens, made further new demands which were successfully met by the company, while wide-screen cinematography, with its horizontal compression of the photographic image, the proper proportions being restored in the process of projection, called for anamorphic lenses and resulted in the company's 'Varamorph' attachment to cope with the different amounts of distortion used in the various wide-screen processes. Aerial reconnaissance photography and television in turn also presented their own peculiar problems, the former giving rise to the Taylor, Taylor and Hobson 'Aviar' lens (developed during the First World War) and the latter to the 'Varital' variable-focus lens which permits of rapid change from 'close-up' to 'distance' without change of intensity over a fixed focal plane. Examples of most of these products were exhibited at the company's works. In connexion with these purely optical developments, it does not seem unfair to single out for special mention the part played by Mr. Arthur Warmisham, director of research for the company during 1922–55, who retired last year after forty-three years of service.

This represents only one side of the company's activities. Very early on, the necessity for replacing the tedious hand-engraving of the necessary data on lens-mounts by something more efficient led to the development by W. Taylor of the now world-famous Taylor, Taylor and Hobson engraving machine and brought the company into the field of machine tool manufacture. Irritation at the lack of standardization and non-interchangeability of parts led him to a close examination of the standards and means of precise measurements of screw threads and to the devising of methods of making screw threads accurate to prescribed limits. This resulted in the development of the thread chasing lathe and the enunciation of the 'Taylor principle': "For a limit gauging system to be effective the 'go' gauge should measure the elements concurrently, while the 'not-go' gauge should measure them independently". It is a pleasing tribute to W. Taylor's abilities that he was elected to the Royal Society in 1934.

The precision needed in the manufacture of optical products necessitated precision methods for testing and gave rise to another important activity, namely, the design and production of instruments for precision testing and gauging, which have found application not merely in optical workshops but also in engineering generally. Many examples of these were exhibited by the company. They fall mainly into two categories, optical and electro-mechanical. Among the former may be mentioned the Taylor Hobson turbine-blade projector and turbine-blade-edge microscope for viewing sections of turbine blades and examining their leading and trailing edges; and also the micro-alignment telescope, now extensively used in the aircraft industry and elsewhere for the alignment over large distances of salient points, lines and planes. In the second category there are notably the 'Talysurf' instrument for the measurement of surface finish and the 'Talyrond' for measurement of errors in surfaces of nominally circular section. These depend on the surface inequalities being transmitted by a diamond stylus to a self-inductance to cause modulations of a high-frequency carrier, the results being recorded on a moving tape or sheet. Also on view were samples showing a fairly new activity of the company, namely, the production by the Bridgeman process of large single crystals of the alkali halides for the manufacture of windows, prisms, etc., for infra-red equipment. Potassium bromide crystals up to nine inches in diameter were shown.

A small historical section was of great interest. It ranged from some early examples of brass-mounted, hand-engraved lenses to articles produced for the War Office during the two World Wars, and included a resplendent 'magic lantern' of the polished mahogany, lacquered brass era; an early model of the engraving machine (treadle operated); and a series of moulds for producing pits on the surfaces of golf balls resulting from W. Taylor's investigations into the conditions needed to produce a straight flight of the ball.

This account gives only a very rough survey of the wide range of equipment and processes shown by the company on this anniversary, but it gives some idea of its achievements in the fields it has set out to serve. It is interesting to note that the direction of the company is now, after seventy years, in the hands of only the second generation, for the present managing director, Mr. Mark H. Taylor, is the son of the original T. S. Taylor.

MUSCLE CONTRACTION IN AN INSECT

A Technique for recording Muscle Contractions in an Insect on a Kymograph

MANY insect muscles are capable of very fast contractions, but it appears that very little work is performed by these contractions. This situation causes some characteristic difficulties in recording them on a kymograph. These difficulties have now been overcome in the case of the muscles of the coxo-trochanteral joint in *Periplaneta americana.* The method devised may prove to be applicable elsewhere.

It was proposed to study the muscles of the coxo-trochanteral joint, which are situated in the coxa (and partly in the pre-coxa). They either stretch or bend the leg at this joint, thus levating or depressing the femur, the latter being nearly immovably connected with the trochanter. Therefore, each movement of the femur may be regarded as a reliable indicator of the activity of the corresponding muscles in the coxa. The recording of these movements on a kymograph, however, is not a simple question.

The first difficulty is to attach a sufficiently light but stiff writing lever to the femur. Its weight should preferably be of the order of that of the femur, tibia, pre-tarsus and tarsus together, amounting to about 7 mgm. Finally, a special writer, weighing about 11 mgm., was designed. It could be inserted into the remaining half of the femur after the other half (including the distal parts of the leg) had been cut away. Thus a solid 'artificial leg' is formed, which very soon sticks to the inner wall of the chitinous 'tube' as a result of drying hæmolymph and tissues.

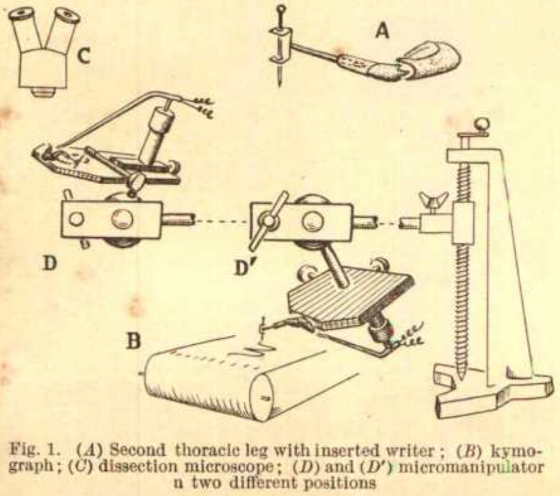

Fig. 1. (*A*) Second thoracic leg with inserted writer; (*B*) kymograph; (*C*) dissection microscope; (*D*) and (*D′*) micromanipulator in two different positions

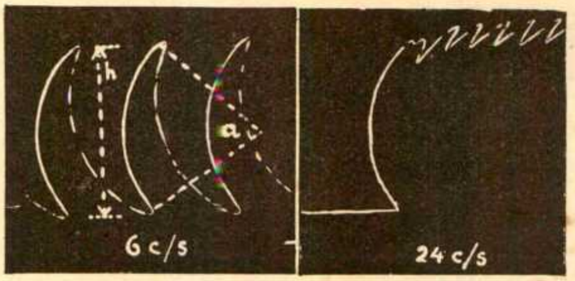

A *B*

Fig. 2. Myograms of muscle 136 + 137. (*A*) Three separate twitches at 6 cycles/sec.; (*B*) twitches partially fused at higher frequency

The smoked kymograph paper offers so much friction to an ordinary recording pin that the insect leg cannot overcome it. For this reason a special writer with a free moving needle was designed (Fig. 1*A*). The kymograph was put in a horizontal position, the needle being held in a vertical position. In this way the friction became very small, as it was only caused by the weight of the needle. This detail proved also very useful, because it eliminates the difficulties of recording due to the disturbing influence of small vertical leg movements.

The moving leg can draw an arc of a circle of about 120° maximum size. Therefore, a cylindrical kymograph cannot be used. The part of the paper on which the records are being made must be a plane (Fig. 1*B*).

As it is necessary to place stimulating electrodes on the nerves, the insect is pinned on its back in a fixed position. Under the dissection microscope, the electrodes are brought into place by means of a micromanipulator. Thereafter the whole complex of preparation, electrodes and micromanipulator can be handled as one rigid unit. This is achieved by the use of a big ball-and-socket joint and some other screws and hinges of secondary importance. It is turned upside-down and the leg can easily be put in a horizontal position and adjusted to the paper (Fig. 1*D*, *D′*).

From Fig. 2 it can be seen that the method described enables the isotonic recording of very fast contractions of frequencies up to at least 24 cycles/sec. It should be noted that neither the heights (*h*) of the records nor the lengths of the arcs (*a*) are proportional to the actual contractions. In most cases, however, this is irrelevant, as only qualitative information is required. If small contractions are considered, of course, this proportionality may be a good approximation.

The question may be raised whether the method is really suitable for an analysis of the functions of the distinct muscles in the coxa. For it is inevitable that muscles which are not under consideration in a given experiment still play a part in the result, just because they are present. Denervated muscles may still influence the records because of their elastic properties, and it is even conceivable that muscles which have been intentionally separated from their apodemes may hinder the movement of the leg because of friction and/or inertness. However, from a number of experiments in which an attempt was made to analyse the importance of these objections, it became clear that they can, in most cases, safely be neglected; these experiments have been designed and carried out by G. Becht.

In a succeeding communication some results obtained with this technique are presented.

I am indebted to J. W. Kuiper, E. D. Nijenhuis and F. J. Oppenoorth for their assistance in the development of this technique; the illustrations have been put at my disposal by G. Becht.

D. DRESDEN

Physiology of the Locomotory Muscles in the Cockroach

IN the course of investigations into the mode of action of insecticides, a detailed study of the nervous system in the cockroach has been planned. This study started with the development of a method for the recording of muscle-contractions (see preceding communication). As only incomplete results were available concerning the anatomy and topography of the sense organs, nerves and muscles (cf., for example, refs. 1 and 2), a detailed study has been carried out on this subject. Most of the results have already been published[3]; some analytical results on the fibres will be published elsewhere. The present communication deals with our first physiological approach to the problem. The muscles which have been studied with the preparation described are the extensors and flexors of the coxo-trochanteral joint, namely: 135*a*, *b*, *c*, *d* and *e*, 136, 137, 138, 139 and 140 (Carbonell's numbering[2]).

Extensors (depressors). As compared with the other muscles, it was especially easy to obtain a good preparation of the system 136 + 137 (innervation: nerve 5, ramus 1) (Fig. 1). This system, which is supplied by one axon, behaves entirely as a fast motor-unit. It reacts with clear twitches up to about 6 cycles/sec., which gradually fuse at higher frequencies (Fig. 2). Some superposition occurs, the tetanic height being approximately 1·2 times that of the twitch. The tetanic contraction fatigues very quickly and it disappears almost completely within a few seconds. Because of its simplicity, it is expected that this preparation will be very suitable as a standard for toxicological work.

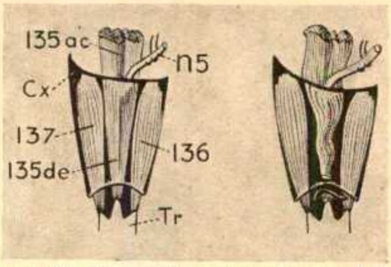

Fig. 1. Medial side of the right mesothoracic coxa of *Periplaneta*. Left: normal. Right: the apodeme of the 135-group has been cut, and the motor-unit 136 + 137 remains

The depressor muscles 135*a* and 135*c* (innervation: nerve 4, ramus 3) represent the strongest group of extensors. They are supplied by very few axons: 135*a* receives three fibres and 135*c* only one. This is reflected in their physiological behaviour. Muscle 135*c* simply behaves as a motor-unit of the fast type, whereas in muscle 135*a* stimuli of successively increasing voltage result in at least three different contraction heights (Fig. 3).

The small band-shaped depressor muscle 135*b* (innervation: nerve 4, ramus 2*b*) is supplied by four axons. It shows scarcely any response to stimuli of low frequencies, up to 25 cycles/sec. Only very minute twitches occur, which could seldom be recorded on the kymograph. Under the dissection microscope, however, they could always be observed very clearly. Stimulation with higher frequencies resulted in a considerable contraction of the 'slow' type. These contractions can last for as long as 10 min. before they exhibit signs of fatigue. If the frequency of the stimuli is increased, the contraction height increases with it, up to a maximum at about 130 cycles/sec. (Fig. 4). In many preparations of 135*b* it was noted that an increase of the voltage of the stimuli induced a rather sharp decrease of the

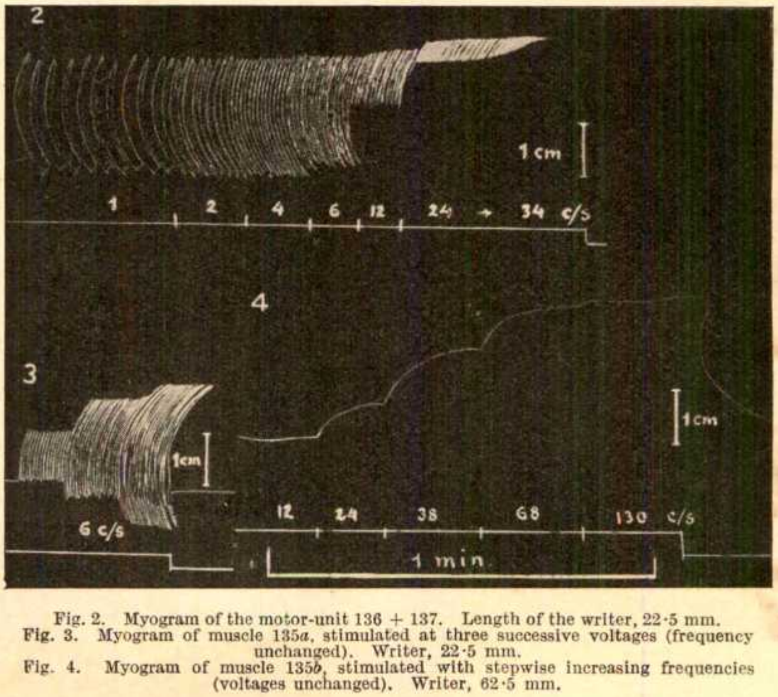

Fig. 2. Myogram of the motor-unit 136 + 137. Length of the writer, 22·5 mm.
Fig. 3. Myogram of muscle 135*a*, stimulated at three successive voltages (frequency unchanged). Writer, 22·5 mm.
Fig. 4. Myogram of muscle 135*b*, stimulated with stepwise increasing frequencies (voltages unchanged). Writer, 62·5 mm.

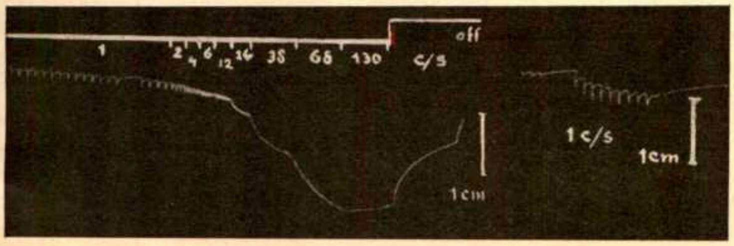

Fig. 5. Myogram of muscles 138 + 139*c*, stimulated with stepwise increasing frequencies (voltages unchanged). Writer, 22·5 mm. Note the 'cock's comb-effect' at 1 cycle/sec.

contraction height. This phenomenon, which was always reversible, points to the existence of an inhibitory fibre in the supplying nerve. Further experiments are needed before a decision can be made on this problem. It is probable that muscle 135*b* will prove to be a very suitable test-object for toxicological investigations on the 'slow-type' muscles.

Flexors (levators). Two groups of levator muscles can be distinguished: 138 and 139*c* on one hand (innervation: nerve 3*B*), and 139*a*, 139*b* and 140 on the other hand (innervation: nerve 6*B*). The nerves supplying the two groups contain at least seven fibres (nerve 3*B*) and exactly seven fibres (nerve 6*B*), respectively. The arrangement of the fibres is rather complicated and will not be discussed here; it is reflected in a more complicated physiological behaviour of these muscles (Fig. 5). Moreover, they all seem to have a 'fast' and a 'slow' component, which adds considerably to the complexity of the system. Records of these muscles have a very characteristic shape which we have called 'cock's comb'-myograms. It is caused by a response to low frequencies (about 5 cycles/sec.) which is intermediate between that of the fast- and that of the slow-type muscles.

These complicated myograms have been analysed a little further in experiments in which ryanodine was administered. Injections of a suitable quantity of this alkaloid result in a very rapid block of the fast muscles (for example, 136 + 137), whereas the slow muscle, 135*b*, is affected at a slower rate. In this respect it is interesting to note that intoxicated insects show a very sluggish behaviour. Now the reaction of 139*a*, 139*b*, 139*c* and 140 to ryanodine consists of disappearance of the fast components (that of 138 is still questionable). These ryanodinized muscles then behave more or less as the slow muscle 135*b*. Therefore, it is believed that the 'cock's comb'-muscles are composed of two different elements, rather than that they represent some sort of intermediate type muscle. However, further evidence is required on this matter.

Some preliminary experiments on the action of γ-BHC on the nerve-muscle preparations have been carried out.

3-HYDROXYANTHRANILIC ACID, A CARCINOGEN PRODUCED BY ENDOGENOUS METABOLISM

By Prof. E. BOYLAND and G. WATSON

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, London, S.W.3

INVESTIGATIONS into the nature of carcinogenesis by polycyclic hydrocarbons were based on the fact that soot and coal tar induce skin cancer in man. Similarly the study of cancer production by 2-naphthylamine started with the observation that this dyestuff intermediate causes cancer of the urinary bladder in men employed in its manufacture. 2-Naphthylamine does not appear to cause cancer of the skin and produces bladder tumours only in man and dogs. The remote action of 2-naphthylamine is probably due to the fact that the immediate carcinogen is not 2-naphthylamine itself but rather one of its metabolites, 2-amino-1-naphthol, which Hueper[1] showed to be carcinogenic following subcutaneous injection into mice. Also Bonser, Clayson, Jull and Pyrah[2] found that this compound induces cancer when implanted into the bladders of mice, under which conditions the parent amine does not.

The technique of testing substances for carcinogenic action by implanting pellets containing the suspected material into the bladders of animals, introduced by Maisin and Picard[3] and developed by Jull[4], is invaluable in the investigation of the role of metabolism in carcinogenesis. By this method, Bonser, Clayson and Jull[5] found that a number of *ortho*-aminophenol derivatives, in addition to 2-amino-1-naphthol, produce cancer of the bladder: these include 1-amino-2-naphthol, 1-methoxy-2-aminonaphthalene and 3-amino-4-hydroxydiphenyl. Clayson[6] has suggested that aromatic amines other than 2-naphthylamine, including butter yellow, 2-acetamidofluorene, 4-aminodiphenyl and 4-amino-stilbenes, may be active after conversion to *ortho*-aminophenols (cf. Walpole, Williams and Roberts[7]).

The tumours of the bladder which appear in the general population do not differ in their pathology from those induced in chemical workers by 2-naphthylamine and other amines such as benzidine and 4-aminodiphenyl. Such tumours might therefore be induced by analogous carcinogens excreted in urine such as metabolites of tryptophan, *l*,3-hydroxykynurenine[8] and 3-hydroxyanthranilic acid[9], which are *ortho*-aminophenols. Experiments described below show that 3-hydroxyanthranilic acid is, in fact, carcinogenic in the bladders of mice.

Previous studies of the metabolism of 2-naphthylamine by tissue slices[10] showed that although 2-naphthylamine is oxidized to aminonaphthols in

Table 1. CHANGES OBSERVED IN BLADDERS OF MICE FOLLOWING INSERTION OF PELLETS OF DIFFERENT COMPOSITIONS

Composition of pellet	No. of mice				
	Original total	Surviving 40 weeks	Showing hyperplasia or metaplasia	With papilloma	With carcinoma
Paraffin wax, m.p. 56°	20	9	1	0	0
3-Hydroxyanthranilic acid (20 per cent) and paraffin wax (80 per cent)	30	19	2	0	3
Cholesterol	25	8	1	0	0
3-Hydroxyanthranilic acid (20 per cent) and cholesterol (80 per cent)	20	14	2	0	4
2-Amino-1-naphthol hydrochloride (20 per cent) and cholesterol (80 per cent)	25	13	1	2	1
8-Hydroxyquinoline (20 per cent) and cholesterol (80 per cent)	20	13	1	2	4

the liver, the aminonaphthols are very rapidly conjugated with sulphate or glucuronic acid so that no appreciable concentration of free aminonaphthol is present in the tissues. No free aminonaphthol is present in the fresh urine of animals dosed with 2-naphthylamine[11]. Urines of man and laboratory animals contain β-glucuronidase, which can hydrolyse one of the metabolites, 2-amino-1-naphthylglucosiduronic acid, and liberate the carcinogenic 2-amino-1-naphthol. Urines from patients with bladder cancer generally contain more β-glucuronidase than do the urines of normal subjects[12].

The carcinogenic action of 2-naphthylamine is thus dependent on its oxidation to 2-amino-1-naphthol in the liver. The conjugated derivatives of this aminophenol are excreted in the urine. One of these, 2-aminonaphthyl sulphuric acid, is resistant to the enzymic action of sulphatase[13], but the 2-amino-1-naphthylglucosiduronic acid may be hydrolysed by urinary β-glucuronidase to liberate the carcinogenic 2-amino-1-naphthol. *l*-3-Hydroxykynurenine and 3-hydroxyanthranilic acid are also excreted in conjugated forms, but the hydrolytic enzymes would liberate the free *ortho*-aminophenols which might induce bladder tumours.

These results indicate a possible mechanism whereby a natural metabolite might induce bladder cancer. The liability to this form of neoplasia would therefore be dependent, among other factors, on: (1) the sensitivity of the bladder tissue; (2) the intake and metabolism of tryptophan. An inborn or induced metabolic pattern might cause an unusual excretion of 3-hydroxy-anthranilic acid derivatives. Somewhat higher concentrations of 3-hydroxyanthranilic acid were found in urines of patients with bladder cancer than were found in urines of normal subjects[14]. (3) The activity of β-glucuronidase and possibly sulphatase in the urine. (4) The average time during which urine remains in the bladder. All these factors would presumably be less effective with increasing dilution of urine.

The carcinogenic activities of 3-hydroxyanthranilic acid in pellets of paraffin wax and of 3-hydroxyanthranilic acid, 2-amino-1-naphthol and 8-hydroxyquinoline in pellets of cholesterol in the bladders of mice have been investigated by a modification of the methods of Jull[4]. The modification consisted in tying off the lumen of the bladder with silk after insertion of the pellet instead of sewing the lumen. By this method the operation is quicker and the risk of leakage of urine during the post-operative period reduced.

The results summarized in Table 1 show that pellets of paraffin wax or cholesterol did not induce carcinomata in experiments lasting 40 weeks, but that pellets containing 3-hydroxyanthranilic acid or 8-hydroxyquinoline produced tumours in a statistically significant number of mice.

The tests with 8-hydroxyquinoline were carried out since it was thought that the known carcinogenic *ortho*-aminophenols might be biologically active because of their power to chelate metals. If they were carcinogenic by virtue of this property, then other chelating agents would be expected to induce cancer. The fact that 8-hydroxyquinoline has induced cancer is in agreement with this hypothesis.

Other constituents of mammalian tissues which can induce cancer include: (1) cholesterol[15], which is not carcinogenic under the conditions of the present experiments; (2) xanthine, which is excreted in urine of xanthinurics[16] and has induced cancer in rats on subcutaneous injection (Haddow, personal communication); (3) œstrogens, which induce tumours at various sites of different species of animals.

The induction of tumours with 3-hydroxyanthranilic acid and xanthine, known constituents of some urines, indicates that cancer might be induced by abnormally large amounts of normal intermediates of amino-acid or purine metabolism. The ability to excrete abnormally large amounts of such compounds might occur spontaneously or be controlled by genetic or nutritional factors.

We should like to express our thanks to Dr. Cuthbert E. Dukes and Dr. E. S. Horning for their willing co-operation in the pathological diagnosis of the material, and Miss M. Allen and Mr. J. L. Everett for assistance in the experiments.

This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. Red-Cell Survival in Familial Hæmolytic Anæmias

When the red-cell hæm of familial hæmolytic anæmia patients is isotopically tagged, as by the administration of glycine-^{15}N, the curves of subsequent isotope-levels may be interpreted in more than one way. Two very different interpretations are given here as subcases of a single model, and their relation to actual cases is discussed.

In cases of spherocytic[1] and sickle cell anæmia[2,3] the ^{15}N-tagged hæm curves show approximately exponential decline following an abnormally rapid and extensive rise. The simplest curve of this kind was reported recently by James and Abbott[3] for a striking case of sickle cell anæmia. As James and Abbott pointed out, their curve has a single-phase decline. This is unlike the multiphasic declines on other and more complicated of the observed curves[1,2].

For simple analysis, assume that the tagged red cells are a single population which is released to the circulation at an exponentially declining birth-rate, and that they are then subjected to a random (or first-order) rate of removal. Distinguishing between these two rates is the most difficult part of interpretation, since evidence is presented that the decline of the curve will follow the slower rate—whether it be the birth-rate or the death-rate. Thus if we let x_0 be total tagging in terms of atom per cent excess of nitrogen-15 in the circulating hæm; b be birth-rate, or daily release fraction of the eventually tagged and yet to be released red cells; t be time after tagging, in days; k be removal-rate, or fraction of circulating tagged cells that are removed daily; and x be concentration of the tag in circulating red cells, in atom per cent excess of nitrogen-15, then our assumptions imply that the daily release of tagged cells will be

$$(x_0 b \exp(-bt)$$

and that the concentration will follow the equation

$$\frac{dx}{dt} = x_0 b \exp(-bt) - kx$$

The solution of this differential equation, which also satisfies the condition that initially $x = 0$, is

$$x = \frac{x_0 b}{(k-b)}\{\exp(-bt) - \exp(-kt)\} \qquad (1)$$

The hæm-tagging curve of equation (1) has the same shape in either of the two possible cases: (I) birth-rate exceeds death-rate ($b > k$), and (II) death-rate exceeds birth-rate ($k > b$). In both cases the declining part of the curve follows the lower of the two rates. Therefore we must use other evidence to distinguish between the rates of release and destruction of the cells.

In cases of familial hæmolytic anæmia, it is almost universally found that the erythroid bone marrow is greatly hypertrophied. This fact can be used to distinguish between the release and removal-rates when it is recalled that in any balanced state the daily production and loss are equal. Thus if M is volume of erythroid marrow, and H is volume of circulating cells, we can choose the normal M to be about 300 c.c. (ref. 4, which gives data implying at least 200, while 300 is more conservative in the present application) and then define hyperplasia ratio as:

$$R_{\text{eryth.}} = \frac{M_{\text{abnorm.}}}{300} = \frac{H}{300}\cdot\frac{k}{b} \qquad (2)$$

Equation (2) uses M as given in ref. 5, in which hV equals the present H. The meaning of this ratio is that: when $R_{\text{eryth.}} > 1$, there is erythroid marrow hyperplasia, and when $R_{\text{eryth.}} < 1$, there is erythroid marrow hypoplasia. Hence if the ratio (k/b) in equation (2) is mistakenly inverted, it has a great effect on one's conclusion about the magnitude of the erythroid marrow.

The whole picture and its importance are easily seen in terms of the beautiful example provided by James and Abbott[3]. Their hæm curve is approximated by the equation

$$x = 0{\cdot}12\,\{\exp(-0{\cdot}052t) - \exp(-t/2)\} \qquad (3)$$

which is the form of equation (1) in which we must choose between

$$\text{I}\ \begin{cases} b = 0{\cdot}5 \\ k = 0{\cdot}052 \end{cases} \text{and II}\ \begin{cases} b = 0{\cdot}052 \\ k = 0{\cdot}5 \end{cases}$$

(The value 0·5 is approximate, since there are not enough early points for better accuracy.) To choose between cases I and II we calculate:

$$R_{\text{eryth.}} = \frac{1{,}040}{300} \times \begin{cases} \text{I} : 0{\cdot}104 \\ \text{II} : 9{\cdot}6 \end{cases} = \begin{cases} \text{I} : \ 0{\cdot}36 \\ \text{II} : 33 \end{cases}$$

where 1,040 represents (0·16 × 385/0·059) from the observed results[3]. While one might expect 10- or 20-fold erythroid marrow hyperplasia in such a severe case of sickle cell anæmia, one would not expect hypoplasia down to less than 40 per cent of normal. For this reason it is highly probable that this is an example of case II, in which the decline of the hæm–nitrogen-15 follows the slower rate of release to the circulation, while the removal of the cells occurs at a faster rate. The observed reticulocytosis of 23 per cent is further support of this conclusion.

In the original report[3] the authors attributed the lower rate to cell removal, but they did not take into account the contraindicating factor of erythroid marrow hyperplasia. Therefore their conclusion, which is the previously common one, should be questioned and re-examined.

The other reported hæm – nitrogen-15 curves for cases of this kind[1,2] are more complicated in having biphasic declines. These can also be treated by the method of this communication if one assumes two populations of cells (analogous to one bimodal population) having different delivery- and/or removal-rates. Again, in these more complicated cases, one must use the erythroid marrow hyperplasia as additional evidence in order to determine whether the slower (decline) rates represent rates of destruction of red cells or rates of delayed release of red cells to the circulation. Here again the presence of marked erythroid marrow hyperplasia implies increase in the ratio (cell destruction-rate : cell delivery-rate).

I thank Drs. D. S. Amatuzio, P. S. Hagen and C. J. Watson for helpful discussions of this and related problems, and the Rockefeller Foundation for a grant at a period during which the last portion of this work was done.

ABO Antigens in the Human Cornea

IT has been found that mammalian cornea is capable of eliciting an immunity reaction and of succumbing to it[1]. The following is a report of findings that human corneas possess *A* and *B* blood-group specific substances. Homogenized corneal tissue, obtained under sterile precautions by trephining the central portion of the cornea from cadavers, not later than 12 hr. after death, was used for adsorption of high-titred normal human sera. To 0·5 ml. of *A*, *B* and *O* sera, diluted 1 : 2 with normal saline, 0·5 ml. of corneal homogenate was added. The adsorption was carried out at 6° C. for 8 hr., the serum–cornea mixture being shaken every 15–30 min. The anti-*A* and anti-*B* titre of the serum was examined against erythrocytes by the double serial dilution method, both before and after adsorption.

It has been found that corneal material from a donor of blood group *A* significantly reduced the anti-*A* titre of *O* antiserum, while the anti-*B* titre remained unchanged. Similarly, corneal homogenate from a donor of blood group *B* reduced only the anti-*B* titre of the *O* serum. Corneas from *AB* donors reduced both the anti-*A* and anti-*B* titre of the serum, while material from donors of blood group *O* was ineffective in reducing either the anti-*A* or anti-*B* titre.

Eluates were prepared after the adsorption by shaking the washed adsorbates in a 56° C. water-bath[2]. The eluates agglutinated red blood cells of the corresponding group.

Twenty samples of corneas belonging to donors of blood groups *A*-5, *B*-5, *AB*-3 and *O*-7 were examined by adsorption and elution experiments. In all cases identity of antigenic substances of the corneal material and erythrocytes has been proved.

Distinct differences in intensity of agglutination were always observed in the last two to three tubes of the titration.

Table 1. TYPICAL RESULTS OF ADSORPTION AND ELUTION EXPERIMENTS

Titre of serum *O* before adsorption	Corneal material from donor of blood group	Titre of serum *O* after one adsorption with corneal homogenate	Titre of eluate against red blood cells
Anti-*A* 1 : 64 Anti-*B* 1 : 128	*A*	1 : 8 1 : 128	1 : 4 1 : 1
Anti-*A* 1 : 64 Anti-*B* 1 : 128	*B*	1 : 64 1 : 64	0 1 : 4
Anti-*A* 1 : 32 Anti-*B* 1 : 64	*AB*	1 : 8 1 : 32	1 : 2 1 : 8
Anti-*A* 1 : 64 Anti-*B* 1 : 128	*O*	1 : 64 1 : 128	0 0

In one case three consecutive adsorptions with corneal material of the same group were performed. The titre of the antiserum was thus reduced from 1 : 128 to 1 : 1.

The question whether failures of corneal transplantation could be explained on the basis of group incompatibility between donor and recipient is under investigation.

Chromatographic Behaviour of Hæmoglobin *E*

RECENTLY, the chromatographic separation of four different human carboxyhæmoglobins (normal adult (*A*), sickle cell (*B*),*C* and fœtal (*F*)) on the ion exchange resin 'Amberlite *IRC* 50' (*XE* 64) has been reported by us[1]. It was shown that these hæmoglobins move down the column at different rates in the sequence $F > A > B > C$. Now we are able to describe the behaviour of a third abnormal human hæmoglobin (*E*), using the same chromatographic method.

The blood samples were obtained from three members of a family of Indonesian origin, which has been described briefly[2]. These three patients were suffering from the heterozygous hæmoglobin *E* disease. Using the elution technique[1] we did not obtain a complete separation of the hæmoglobin *A* and *E* present. With the cuvette method, however, the two hæmoglobins were separated quite well (Fig. 1,I). Even a mixture of five different human hæmoglobins can be separated completely into the original components. The rate of displacement of the hæmoglobin *E* is intermediate between those of the normal adult and sickle cell hæmoglobin ($A > E > B$, Fig. 1,III).

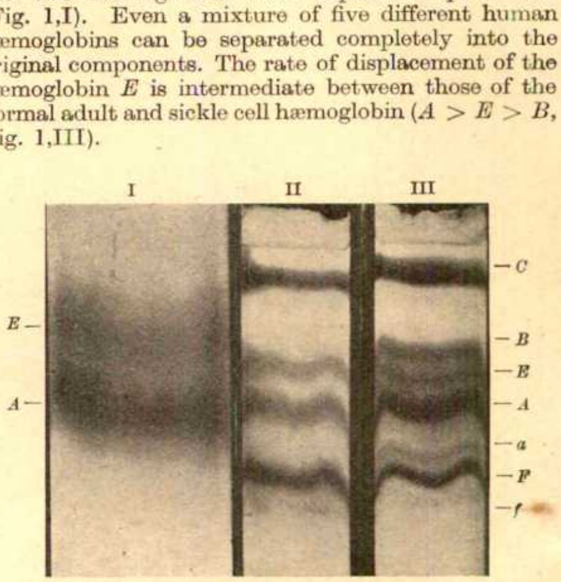

Fig. 1. Chromatographic separation of hæmoglobin-*E* and other human hæmoglobins. I, Hæmoglobin of a patient with heterozygous hæmoglobin-*E* disease; II, artificial mixture of four hæmoglobins (*C*, *B*, *A* and *F*); III, artificial mixture of five hæmoglobins (*C*, *B*, *E*, *A* and *F*)

In these experiments the presence of well-separated but less intense bands of the corresponding major fractions of the various hæmoglobins sometimes occurs (Fig. 1,III *a* and *f*). This is especially the case when the rate of flow of the effluent is low. Also with our elution technique the separation of one hæmoglobin into two components is possible. The first fraction, which represents about 10 per cent of the total amount, moves down the column more rapidly than the major fraction. It may be that this chromatographic inhomogeneity of one hæmoglobin is the same as that reported recently by Morrison and Cook[3]. With our technique, however, we never found a third fraction with a lower rate of displacement.

These investigations were supported by a grant of the Nutricia Co., Zoetermeer, The Netherlands.

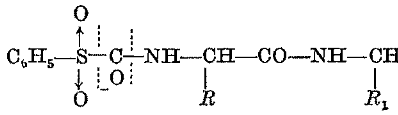
New Methods for the Synthesis of Peptides

In 1947, Ehrensvard suggested the use of a new protective group for peptide synthesis[1]. According to his investigations, the phenylthiocarbonyl grouping (C_6H_5—S—C—O—) can be used advantageously for the protection of the amino-groups of amino-acids. The phenylthiocarbonyl-group could be split off from the N-phenylthiocarbonyl-peptide derivatives by means of lead acetate. Lindenmann, Khan and Hofmann[2] confirmed Ehrensvard's observations; but according to their investigations hydantoins, not peptides, resulted under the influence of lead acetate. As no method was given for splitting off the phenylthiocarbonyl-group, we attempted the application of oxidative methods, and with complete success. The oxidation is carried out with 2·5 moles of perbenzoic acid at − 5° in acetic acid – benzene, benzene – tetra hydrofurane, dioxane or dioxane containing preferably 2 per cent of water. The products of oxidation probably represent a type of mixed anhydrides of carbamic acids with sulphinic acids hitherto unknown:



$$C_6H_5\text{—}\overset{\overset{O}{\uparrow}}{\underset{\underset{O}{\downarrow}}{S}}\text{—}\underset{\underset{}{O}}{C}\text{—NH—}\underset{\underset{R}{|}}{CH}\text{—CO—NH—}\underset{\underset{R_1}{|}}{CH}\text{—COO}R_3$$

(I)

With water, compounds of type (I) disintegrate immediately at the places marked with broken lines, even at − 5°, with the evolution of carbon dioxide, and the corresponding peptides or amino-acids are isolated in excellent yield, by adsorption on a 'Dowex 50' cation exchange resin and elution with diluted ammonia. (When esters are used, it is necessary to carry out the usual alkaline saponification before working them up.) By this procedure, glycine was obtained from phenylthiocarbonyl glycine (yield 74 per cent), glycyl-alanine from ethyl-phenylthiocarbonyl-glycyl-alaninate and L-glutamyl-L-tyrosine from ethyl-phenylthiocarbonyl-L-glutamyl-L-tyrosinate (33 per cent).

A drawback to the use of the phenylthiocarbonyl-group is that only amino-acid esters can be acylated with the chloride[3], so that starting from an amino-acid it takes four steps to prepare a protected amino-acid. Therefore, maintaining the structural principles of phenylthiocarbonyl-derivatives, we prepared[4] methyl-thiocarbonyl-chloride from phosgene and from methylthiol, which is a weaker acid than thiophenol. With this compound the amino-acid anions can be acylated (in water, in the presence of sodium bicarbonate, sodium carbonate or magnesia). Methylthiocarbonyl-glycine (m.p. 118–119°), ethyl-methylthiocarbonyl-glycinate (m.p. 55°), methylthiocarbonyl-threo-β-phenyl-serine (m.p. 129–130°), ethyl-methylthiocarbonyl-threo-β-phenylserinate (m.p. 124°) have been prepared with an average yield of 65–80 per cent. Peptides can be prepared from methylthiocarbonyl amino-acids in the same manner as from phenylthiocarbonyl amino-acids.

However, it has proved more advantageous to use N-benzylthiocarbonyl derivatives instead of methylthiocarbonyl compounds, because they crystallize better and are sparingly soluble in water. We prepared benzylthiocarbonyl-chloride (m.p. 12°; b.p.$_{0 \cdot 01}$ 65°), which was hitherto unknown, by the same method as methylthiocarbonyl-chloride. With benzylthiocarbonyl-chloride the amino-acids and peptides can be smoothly acylated (see Table 1). Acylating amino-acid and peptide esters with benzylthiocarbonyl-chloride in chloroform solution, ethyl-benzylthiocarbonyl-glycinate (oil) and ethyl-benzylthiocarbonyl-glycylglycinate (m.p 119–120°) were prepared in yields of about 80 per cent. Ethyl-benzylthiocarbonyl-glycylglycinate was prepared from benzylthiocarbonyl-glycylchloride (prepared with thionyl chloride) in a yield of 91 per cent, by the mixed anhydride method of Th. Wieland, Boissonnas, and Vaughan (yield 43 per cent), by the phosphoaza method of Goldschmidt (yield 81 per cent) and by Sheehan's new N-N′-dicyclohexylcarbodiimide method[5] (yield 74 per cent). With this last method, ethyl-benzylthiocarbonyl-alanyl-glycinate (m.p. 120–121°, yield 70 per cent), ethyl-benzylthiocarbonyl-glycyl-phenylalaninate (m.p. 108–109°, yield 70 per cent), and ethyl - benzylthiocarbonyl - L - alanyl - glycinate (m.p. 105–106°) were also prepared.

Glycine was acylated to benzylthiocarbonyl-glycylglycine with benzylthiocarbonyl-glycylchloride in water-dioxane in the presence of magnesium oxide in a yield of 43 per cent (m.p. 177–179°).

From the benzylthiocarbonyl-derivatives the benzylthiocarbonyl-group can be split off with perbenzoic acid in exactly the same manner as the phenylthiocarbonyl-group from phenylthiocarbonyl-derivatives. The yields of the peptides were about 65–70 per cent.

We expect that the benzylthiocarbonyl-group could be used, among other syntheses, in particular for the synthesis of peptides of lysine, arginine and ornithine. The benzylthiocarbonyl-group being insensitive to hydrobromic acid, its combined use with the carbo-

'Malic Enzyme' Activity in Blowfly Muscle

An investigation of the metabolism of sarcosomes and whole-muscle homogenates isolated from the flight-muscle of the blowfly (*Calliphora erythrocephala*) indicated that the rate of succinate oxidation by these preparations is limited by the steady-state concentration of oxaloacetate produced by further oxidation of fumarate (Lewis, S. E., and Price, G. M., unpublished observations).

The addition of Mn^{++} to these preparations produced a marked stimulation of succinate and malate oxidation. Similarly, the addition of co-enzyme II stimulated the oxidation of both these substrates. These findings suggest that the preparations may contain a co-enzyme II – Mn^{++}-dependent enzyme similar to the 'malic enzyme' found in vertebrate liver[1]. This enzyme reversibly catalyses the oxidative decarboxylation of malate to pyruvate and carbon dioxide at *p*H 7·35 [2]. Since this reaction provides an alternative pathway for malate oxidation, not involving the formation of oxaloacetate, it may be expected to facilitate the oxidation of succinate. The reactions associated with the 'malic enzyme' were therefore examined in an aqueous extract of an acetone-dried powder prepared from blowfly thoraces.

The reduction of co-enzyme II by this extract was measured spectrophotometrically at a wave-length of 340 mμ. The results obtained are shown in Fig. 1. On addition of malate a rapid reduction of co-enzyme II was observed, and in samples to which Mn^{++} was added the rate of this reaction was increased. Under the conditions of this experiment co-enzyme II could not be replaced by co-enzyme I, either in the presence or in the absence of Mn^{++}. When the reduction of co-enzyme II had ceased, the addition of pyruvate in bicarbonate saturated with carbon dioxide resulted in a rapid re-oxidation of the reduced co-enzyme. Since the addition of pyruvate alone caused some re-oxidation of reduced co-enzyme II, this was probably due in part to the presence of lactic dehydrogenase, which we have since shown to be present in our extracts. However, the increase in the oxidation of reduced co-enzyme II which occurs when carbon dioxide and pyruvate are added together suggests that a 'malic enzyme' is also present.

When estimating 'malic enzyme' activity by measuring the reduction of co-enzyme II, Ochoa *et al.*[3] defined one enzyme unit as "the amount of enzyme causing an increase in optical density of 0·01 per minute". On this basis our extract contains 20 units in 4 mgm. of protein, which is equivalent to a specific activity of 5, and is equal to that reported in similar extracts from pigeon liver[2]. Recently a similar enzyme has been shown to be present in hæmolymph from the larva of the silkworm (*Bombyx mori*)[4].

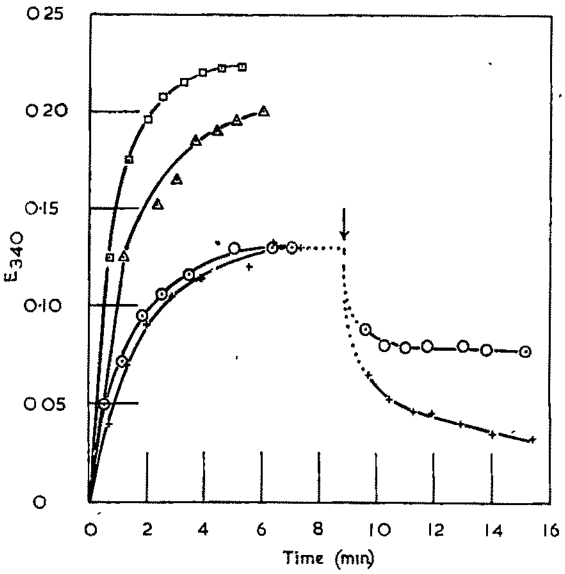

Fig. 1. Reduction of co-enzyme II in the presence of malate; its reversal by pyruvate and carbon dioxide, and activation by Mn^{++}.
△, Control; □, control + Mn^{++}; ○, control + Mn^{++} + 100 μmoles pyruvate added at arrow; +, control + Mn^{++} + 100 μmoles pyruvate in 1 3 per cent bicarbonate saturated with carbon dioxide, added at arrow. Cells contained. extract 0·5 ml; malate (1 33 × 10^{-3} *M*); 'tris' buffer *p*H 7·25 (2 × 10^{-1} *M*); co-enzyme II (6 74 × 10^{-4} *M*); manganous chloride (6 67 × 10^{-4} *M*); water to total volume of 3 0 ml.
(The effect of Mn^{++} and the effect of Mn^{++} plus pyruvate were examined with separate extracts)

Since many 'malic enzyme' preparations also catalyse the decarboxylation of oxaloacetate, the decarboxylase activity of our extracts was also examined. The carbon dioxide produced from oxaloacetate was measured manometrically in the presence of various amounts of extract in the presence and absence of Mn^{++}. The rate of carbon dioxide production was measured during the 5–25 min. period after the addition of oxaloacetate, and, after deducting the value for the spontaneous carbon dioxide production, the Q_{CO_2} values were calculated on the basis of the protein content of the extract. The results given in Table 1 show that the extract catalyses the decarboxylation of oxaloacetate. The fact that the Q_{CO_2} values are reasonably constant shows that the carbon dioxide production is proportional to the amount of extract present. When the Mn^{++} was omitted from the reaction mixture the rate of carbon dioxide production was reduced, both in the presence

Additions to reaction medium	CO_2 produced (μl./hr) Observed	Corrected	Q_{CO_2}
None	164	—	—
0·4 ml. extract *A*	200	36	10·9
Mn^{++}	310	—	—
0·2 ml. extract *B* + Mn^{++}	369	59	27·5
0·4 ,, ,, ,, ,,	408	98	22 8
0·8 ,, ,, ,, ,,	501	191	22·2

Reaction medium. Acetate buffer 0·1 *M* (*p*H 4·5); oxaloacetate 0·02 *M*. Extract *A* contained 8 4 mgm. protein per ml.; extract *B* contained 10 75 mgm. protein per ml; manganous chloride 10^{-3} *M*. (Final volume 3 ml. Temperature 25° C.)

and absence of the extract, and the Q_{CO_2} was reduced also.

The oxaloacetate–decarboxylase activity of this extract is of the same order as that reported for similar extracts from vertebrate tissues[5]. However, since native proteins may catalyse the spontaneous decarboxylation of oxaloacetate the carbon dioxide production in the presence of bovine plasma albumin and Mn++ was examined. This protein increased the rate of carbon dioxide production by 20 µl. per hr., whereas a sample of the acetone-dried powder extract, containing an equal amount of protein, produced an increase of 98 µl. per hr.

Although these extracts catalyse the reactions associated with the 'malic enzyme' we have no evidence to suggest that, in our preparations, both reactions are catalysed by a single enzyme. Evidence on this point can only be obtained after isolation of the systems involved.

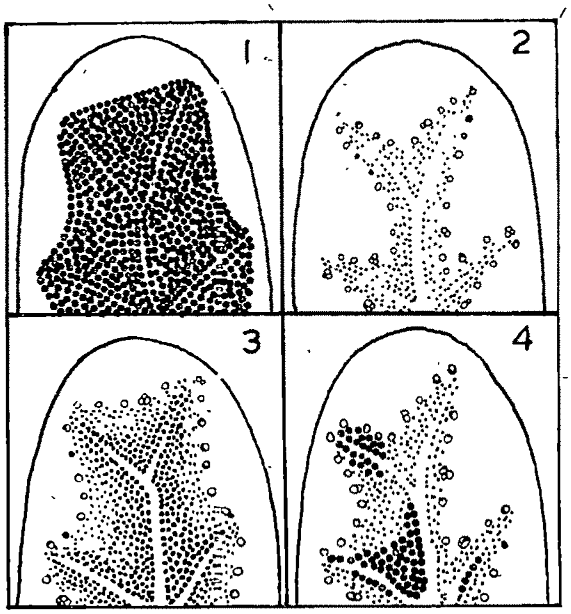
Zymogen Formation in the Mouse Pancreas

There are present in the Golgi zone of each acinar cell of the mammalian pancreas a number of small lipoidal droplets (about 1½µ in diameter) which stain with methylene blue and other vital dyes. Each lipochondrion, or, where vesiculated, its cortex, is intensely osmiophilic and concentrates vital dyes[1]. Hirsch[2], and later Baker[3] and Lacy[4], considered that the prozymogen granules arose within the vacuolated lipochondria and when mature (1½µ in diameter) were released into the apical part of the cell.

The prozymogen granules, however, do not form in the lipochondria, but so far as can be determined with the light microscope, form *in situ*. They arise as small refractile granules at the limit of resolution in size and well spaced from each other, their centres being separated by about 1½µ (Fig. 2). The prozymogen granules, like the mature zymogen, do not concentrate vital dyes and are no more osmiophilic than the cytoplasm. No zymogen or prozymogen granule was ever observed within the interna of the lipochondria.

The observations were made on stained and unstained living pancreas *in vitro* and confirmed on pancreas with intact circulation, and also on material fixed on the slide with osmic acid and various osmic acid mixtures. Repeated intravenous injections of 0·5 c.c. of a 2 per cent solution of pilocarpine every forty minutes over a period of several hours was found the most suitable method for obtaining more or less synchronous and complete discharge of the pancreases of twelve-weeks old mice. The complete cycle of discharge and restitution in the most advanced cells took six hours.



Portions of pancreatic acini in various phases of restitution. 1, full pancreas. Mature zymogen, 1½µ in diameter Lipochondria not shown. 2, early phase of restitution. Prozymogen granules near limit of resolution in size. 3, Middle phase of restitution. First formed apical prozymogen larger than more recently formed basal prozymogen 4, In some of the cells remnants of undischarged mature zymogen are present Prozymogen granules have formed distally to these remnants as well as elsewhere. The vesiculated and non-vesiculated, simple and compound, bodies at the basal edge of the zymogen and prozymogen masses are the lipochondria or Golgi bodies

The onset of prozymogen formation does not require the complete prior discharge of the full pancreas cell. In a cell which has ceased to discharge, having lost only half its mature zymogen granules (or, possibly, even less), prozymogen begins to form immediately basally to the remaining zymogen. This may also be observed in sections of material fixed in Flemming without acetic mixture, stained with analine acid fuchsin and differentiated with methyl green, where the mature granules stain a yellow colour and the smaller prozymogen red. Where the discharge of zymogen goes on to completion, the new prozymogen first forms at the very apex of the cell. Later, prozymogen granule formation extends basally. Thus there is a continuous production of prozymogen, the full complement of granules not being laid down simultaneously. In a fully discharged cell which is well on the way to complete restoration of its zymogen complement, a gradation in size of prozymogen granules from the more advanced apical to the less advanced and more basal ones can readily be seen (Fig. 3). Thus the apical granules may have reached 1µ in diameter while the basal ones have only recently formed and are just visible. Only in the well-rested pancreas are all the granules mature, about 1½µ in diameter. Depletion of the cell occurs either by direct discharge of granules into the lumen, or indirectly by discharge into the long-necked retort-like vacuoles found in discharging cells, in particularly great abundance in animals heavily dosed with pilocarpine or pancreozymin and secretin. The walls of these vacuoles appear to be no more osmiophilic than the cell membranes. Among the fused and unfused zymogen granules present in these vacuoles some discharged lipochondria may also be found.

During discharge the lipochondria remain among, and immediately basal to, the most basal zymogen granules, and on complete discharge lie at the apical surface of the cell. As prozymogen granules form between the lipochondria and either the apical cell wall or the most basal part of the remnant zymogen granules, the lipochondria mark the boundary of the newly formed granules.

Where a mature zymogen granule and a heavily stained lipochondrion were in very close proximity, the latter, on myelination in appropriate solutions, often applied itself to the surface of the zymogen granule, so giving the appearance of a lipoidal sheath around a mature granule. The large blue (not purple) 'puddingstone' masses studied superficially with a number of mature zymogen granules, observed by Worley[5] in resting frog pancreas heavily stained with methylene blue and crushed in Ringer solution, are another type of artefact arising from lipochondria on the way to forming vacuome–crinome bodies[1] as a result of mechanical damage of the vitally stained cells.

A full report of this work is being published elsewhere.

Synthesis of β-Galactosidase in *Ophiostoma multiannulatum* and Some Properties of the Enzyme

THE ascomycete *Ophiostoma multiannulatum* (Hedgc. and Davids.) can grow on a synthetic liquid medium containing salts, vitamins (B_1 and B_6) and a suitable carbon source. In connexion with the development of a method for continuous culture of the fungus[1], some studies on the ability of the organism to utilize different carbon sources were made. More or less pronounced adaptive growth was observed with lactose, cellobiose, raffinose, glycerol and ethyl alcohol, whereas galactose was not metabolized. The growth lag was considerably shortened in the presence of a mixture of amino-acids, and this fact suggested a more detailed study of the factors influencing the synthesis of some of the enzymes involved.

It seemed desirable to investigate β-galactosidase first, as comparative data were available from several other organisms (see, for example, refs. 2–5). The enzyme was assayed by the technique originally described by Lederberg[6] under conditions which give a zero-order reaction with respect to substrate, *ortho*-nitrophenyl-β-D-galactoside.

Different mutant strains of the fungus have been shown to produce varying amounts of the enzyme, but work has been concentrated on a wild strain, *O. multiannulatum* 51. This strain grows in the form of budding conidia at 25–30° C. and, with good aeration, with a minimal mean generation time of about three hours. During the growth, β-galactosidase appears in the medium, but no measurable enzyme activity has been found in the cells. All methods tried for the extraction of fresh or lyophilized cells have failed to give more than mere traces of enzyme. If an enzyme preparation obtained from the medium is mixed with the cells, the enzyme activity is not lost during such extraction procedures. When the fungus is grown on lactose, the enzyme can be obtained from the medium at an early stage of growth, which also indicates that the β-galactosidase of *O. multiannulatum* is an exo-enzyme, in contrast to what has been found in bacteria and *Neurospora*. The enzyme synthesis is inhibited by a glucose concentration higher than 0·05 mgm./ml. in the medium, and when the cells are grown on 0·5 per cent glucose in ordinary shake-culture flasks, no enzyme can be detected until the glucose concentration falls below this value. In a continuous culture, with glucose as growth-limiting factor and with excess nitrogen, a considerable production of enzyme is obtained both at 25° and 30° C.

A partial purification of the enzyme has been accomplished by chromatography and electrophoresis. After the cells had been centrifuged from an immature culture on lactose, the supernatant solution was adjusted to *p*H 7·2 and made 0·02 *M* with respect to tris(hydroxymethyl) aminomethan-hydrochloride buffer (Sigma Chemical Co., *Tech. Bull.* 106), *p*H 7·2. The enzyme could then be quantitatively adsorbed directly on 'Dowex 2' in equilibrium with that buffer according to the technique described by Boman[7]. With 0·2 *M* buffer, more than 90 per cent of the enzyme activity is eluted, leaving about 80 per cent of the protein impurities on the column. After dialysis against 0·01 *M* acetate buffer, *p*H 5·0, the enzyme has been further purified by chromatography on calcium phosphate according to Tiselius[8].

The enzyme preparation is stable even at room temperature in a buffer composed of 0·1 *M* pyridin adjusted with acetic acid to *p*H 5·5, and preliminary experiments show that impurities can be removed by zone electrophoresis employing the apparatus of Porath[9] and the cellulose powder of Flodin and Kupke[10]. By using a volatile buffer system, it is possible to obtain concentrated salt-free preparations of the enzyme by lyophilizing the eluate from the column—a simple method which would seem to be applicable to all enzymes stable under these conditions.

Kinetic studies made on some of these preparations show that the enzyme reaction with *o*-nitrophenyl-β-D-galactoside is competitively inhibited by lactose and non-competitively by glucose. The optimum *p*H of the reaction is about 5, but trivalent anions such as phosphate and citrate move the optimum to higher values much as described by Landman and Bonner[4] for the β-galactosidase of *E. coli*. An Arrhenius plot of the reaction-rate between 20° and 40° C. gives a straight line, but more detailed kinetic observations have been postponed until purer preparations from different strains are available for comparison.

The stability of the enzyme in crude preparations is remarkable. At 65° C., 50 per cent inactivation is obtained after about 20 min. in acetate buffer *p*H 5, and at 30° C. it is stable between *p*H 3 and 8 for several hours. As the purity is increased, this stability seems to be appreciably reduced, probably because of the removal of some stabilizing impurity.

A[1] detailed report of this work will appear later. I wish to thank Prof. A. Tiselius and colleagues at this Institute for helpful discussions. The cost of this work is being defrayed in part by grants to the Institute from the Rockefeller Foundation.

Decomposition of Xylan by *Sporocytophaga myxococcoides*

That *Sporocytophaga myxococcoides* is unable to grow on xylan and xylose has been shown by several investigators[1]; for that reason the organism was used in an investigation to find if cellulase is able to decompose xylan. Fuller and Norman[2] report a disappearance of xylan from corn stalk cellulose during growth of *Sporocytophaga myxococcoides*.

Two strains have been used; our own was isolated by Dr. H. L. Jensen and another was obtained from Prof. A. J. Kluyver, of Delft. The purity of the cultures was regularly checked by streaking on xylan agar and glucose asparagine yeast extract agar or meat peptone agar.

Strips of absorbent cotton-wool (0·2 gm., 6–8 cm. long) were placed in test tubes; 5 ml. of a medium containing 0·5 per cent wheat straw xylan in a colloidal solution in addition to inorganic nutrients (ammonium nitrate, 0·1 per cent; dipotassium hydrogen phosphate, 0·05 per cent; magnesium sulphate, 0·02 per cent; sodium chloride, 0·02 per cent; ferric chloride, 0·002 per cent) was added, and the cotton-wool was arranged like agar slants. After autoclaving at 115° for 20 min., the tubes were inoculated by moving a little piece of filter paper covered by growth of *Sporocytophaga* gently over the surface of the cotton-wool, and incubated at 30°. Every third day tubes were removed from the incubator for analysis, the purity of each culture was checked by streaking as mentioned above, the liquid was removed and brought to 5 ml., reducing power was determined in 1 ml., and the remainder was used for paper chromatography.

Reducing power[3] increased regularly in the tubes containing cotton-wool plus xylan, as seen in Fig. 1. A small increase was observed on cotton-wool alone. No growth took place on xylan alone.

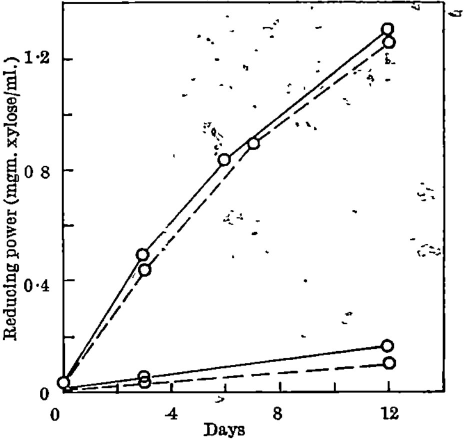

Fig. 1. Reducing power in cultures of *Sporocytophaga myxococcoides* growing on cotton-wool + xylan (upper curves) or cotton-wool alone (lower curves). Continuous line, Lyngby strain; broken line, Delft strain

The paper chromatograms from cultures on cotton-wool plus xylan showed an accumulation of xylose, arabinose, xylobiose, xylotriose and trace of glucose; these are the same reaction products which have been found in previous studies on enzymatic decomposition of xylan[4]. The small increase in reducing power in cotton wool alone was caused by xylose, arabinose and compounds containing uronic acid. These presumably originated from accompanying hemicellulose, since xylose, arabinose and uronic acid were released by treating the cotton-wool with boiling 0·5 *N* sulphuric acid but are not found in aqueous extracts of *Sporocytophaga* grown on glucose agar.

Cell material grown on cellulose or glucose and precipitated in acetone was able to split xylan at almost the same rate. Slight xylan-splitting activity was found in a filtered fluid (Jena glass filter 11 *G* 5) from a cellulose culture.

These experiments suggest that the cellulase of *Sporocytophaga myxococcoides* is able to split xylan; other explanations might, however, be possible. This property is interesting from the point of view of the ecology of the soil micro-organisms, since other organisms might in this way be provided with easily available carbohydrate material.

A more detailed account of this work will appear later.

Leaf Movements and the *Tagesrhythmik* Explanation of Photoperiodism

Bünning's[1] hypothesis of the relationship between day-length responses and diurnal rhythms as manifested by leaf movements has been the object of several recent criticisms[2-4] as inconsistent with some facts of photoperiodic induction. However, Bünning's scheme is not only a theory of photoperiodism but also a generalization concerning diurnal leaf movements.

Fig. 1 shows a selection of records of the diurnal change of leaf position in *Bauhinia monandra*. The positions were recorded on 16-mm. film using a camera triggered every fifteen minutes. It will be seen that although the shapes of the phases are not exactly as in Bünning's idealized diagrams, the general

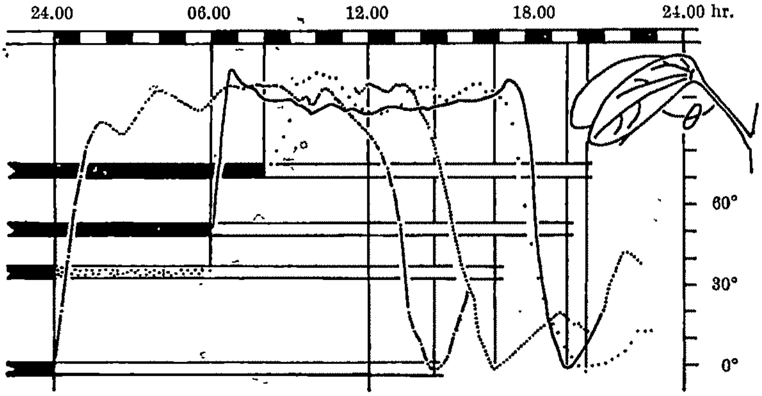

Fig. 1. *Bauhinia monandra.* Changes of leaf angle after beginning illumination at midnight, 6 a.m. and 8 a.m. and (stippled band) at midnight, but with weak light until 6 a.m. In each case the plants were darkened from 6 p.m. the previous evening

features are evident and, in particular, the *hebung* phase begins immediately after illumination as in his diagram for short-day plants. This, of course, might be expected in a tropical species accustomed to a 12-hr. day in Nature.

Nevertheless, if the times from beginning illumination to the onset of downward movement (that is, the duration of the 'photophile' stage in Bünning's terminology) are compared among the graphs, they are obviously not constant. However, the point of beginning downward movement is ill-defined in these records, and as it has also proved very susceptible to extraneous conditions such as humidity, and also age of the leaf, it is doubtful whether it can be regarded as a critical point in the cycle. On the other hand, the timing of the middle point of leaf closure is sharply defined and has proved very uniform after any particular alternation of darkness and illumination. Counting, then, this middle point of closure as the limit of the photophile stage, it has been found that, independently of the time of darkening the previous day, the 'normal' photophile phase of a little more than 12 hours duration (illustrated by illumination at 6 a.m. in Fig. 1) is only adhered to if the duration of the preceding dark period also approximates to 12 hr. With shorter dark periods (as with illumination at midnight) the photophile phase is lengthened; with longer (as with illumination at 8 a.m.) it is shortened. Exactly similar relationships to the length of the previous dark period appear to hold for the related species *B. tomentosa* and also for an unrelated plant, *Talinum triangulare*.

It would then appear that leaf movement in these examples closely parallels the photoperiodic behaviour of short-day plants such as *Xanthium*, in which flowering is said[5] to be dependent on the duration of the dark period. Bünning himself[6] has made a special exception for *Xanthium* from his general rule that the cycle of leaf movement is initiated in the first instance by change from dark to light. In this case, he says, the cycle is set in operation by a change from light to darkness. It is evident, however, that both changes are involved in determining the length of the photophile phase in *Bauhinia* and *Talinum*: agreeing exactly with the photoperiodic behaviour of short-day plants.

There is a second respect in which the leaf movements of these plants seem to agree better with reported features of photoperiodism than with Bünning's generalizations: the effect shown in Fig. 1 of beginning illumination with a period of weak light, which in this case was about 30 foot-candles compared with 600 foot-candles for the rest of the period. It will be seen that this treatment produced the longest photophile phase of all, as if the weak light had made the previous dark period in effect even shorter. Schwabe[7] has provided a parallel in photoperiodism with the observation that when part of the light period in each day is provided by weak light, the effective length of the accompanying dark period in controlling flowering is reduced. In Bünning's schemes, of course, the cycles are controlled by the timing of illumination, not at all by its intensity.

A few other inconsistencies with Bünning's sequences have been noted. For example, when illumination is continued without further intervention of dark periods, the rhythm set up by the initial exposure to light does not continue endogenously, but rapidly decreases in amplitude and is practically indistinguishable after three days. Moreover, although the limits of the phases rapidly become indistinct, it is nevertheless clear they recur after decreasing intervals of time. It appears probable that control of the cycle by the initial illumination scarcely persists beyond the first closure phase, for it is only this phase which shows the strict timing evident in Fig. 1. Referring to the figure again, it also appears doubtful whether any part of the cycle but this first closure is indeed controlled by illumination, for although Bünning postulates that the first effect of transfer to light is invariably the initiation of upward movement of the leaves, these records show that in *Bauhinia* upward movement had already begun before the end of long dark periods. Schwabe[8] has reported an exactly similar behaviour of stomatal aperture. In *Talinum*, on the other hand, the 'opening' phase that is in progress at the beginning of a normal light period is actually a downward movement of the leaves and this, too, begins before daybreak. In *Bauhinia* the rapid opening on first bringing into the light has presumably nothing to do with the diurnal cycle on which it is superimposed, for a similar immediate response may be induced at any time of day by altering light intensity, and apparently without any effect on the timing of the subsequent closure phase. Significantly, the leaf position of *Talinum* is not detectably affected by change of intensity in the daytime and neither is there evidence of accelerated opening when this plant is first brought into the light.

Effect on Crop Growth of Rain after Prolonged Drought

An investigation of the effect of irrigation on the growth of the sugar beet crop was started in 1955 at Woburn, Beds. Measurements of dry weight and leaf area were made on samples of the crop taken from twelve plots, six of which were irrigated. The experiment also included a comparison of two rates of nitrogen supply, but for the present purpose this can be ignored; the results in Table 1 are means for the two rates. Material was available for sampling on only three occasions, as most of the crop had to be kept for measurement of yield at the normal time of harvest.

Table 1. Effect of Irrigation on Dry-matter Yield and Leaf-area Index of a Sugar Beet Crop on (1) July 27, (2) August 10 and (3) August 24, 1955, and on Net Assimilation Rate, Relative Leaf-growth Rate, and the Increment of Dry-weight Yield in the Intervals between Times 1, 2, and 3

	Dry weight (gm /m.^{2})			Leaf-area index		
Time	1	2	3	1	2	3
Irrigated	226	531	704	1·43	2·35	2·60
Not irrigated	187	300	544	1·03	1·04	1·62
S.E	14	36	56	0·08	0·12	0·17

	Net assimilation rate (gm /m ^{2}/week)		Relative leaf-growth rate (per cent per week)		Dry-weight increment (gm /m ^{2})	
Interval	1–2	2–3	1–2	2–3	1–2	2–3
Irrigated	83	34	26	5	305	173
Not irrigated	53	96	0	20	113	244
S.E	8	14	3	6	30	59

No rain had fallen for three weeks before the first sampling on July 27, and the estimated water deficit on the unirrigated plots was then 4 in. On the irrigated plots it was kept below 1 in. by appropriate irrigation throughout the growth period. The dry-weight yield and leaf-area index (*L*, ratio of leaf area to land area) of the irrigated crop (Table 1) were already much greater than those of the unirrigated crop. There was no rain in the following fortnight, and at the second sampling on August 10 the estimated water deficit on the unirrigated plots had increased to 5 in.; the effect of irrigation on dry-weight yield had also greatly increased. The net assimilation rate (*E*) of the irrigated plants in the interval between July 27 and August 10 was significantly greater than that of the unirrigated plants. On the unirrigated plots, *L* did not increase during the interval, but it increased so much on the irrigated plots that on August 10 it was more than doubled by irrigation. Because of the large effects on both *E* and *L*, the increment of dry-matter yield between July 27 and August 10 was nearly trebled by irrigation.

During the next two weeks, 0·6 in. of rain fell, but in spite of this the estimated water deficit of the unirrigated land had increased to nearly 6 in. on August 24. For the irrigated plants, *E* was less than in the previous period, presumably because of changes in environmental factors other than water supply, but for the unirrigated plants it was greater than before. Consequently, in the second period the effect of irrigation was reversed and *E* was nearly three times as great for the unirrigated as for the irrigated plants. During the second period also, *L* increased more, both absolutely and relatively, on the unirrigated plots, but on August 24 it was still much smaller than on the irrigated plots. However, *E* was so much greater for the unirrigated plots that in spite of *L* being smaller the increment of dry-matter yield was larger, though not significantly, than on the irrigated plots.

These results show that, after prolonged drought, rainfall in amounts very small compared with the soil-moisture deficit, and therefore with amounts used in orthodox irrigation practice, caused such large increases both in leaf growth and in the rate of photosynthesis of unirrigated plants that, temporarily, these plants grew faster than irrigated ones that had never been subjected to severe water stress. It is intended to repeat this work (though the same conditions may not recur in the field in 1956) and, if possible, to imitate the conditions of water supply in laboratory experiments. If the results are confirmed, they may have an important bearing on the efficient use of irrigation water.

Polymorphism and Parthenogenesis in a Ptinid Beetle

Ptinus latro Fab. (1775) and *P. hirtellus* Sturm (1837) (Coleoptera, Ptinidae) have for long been accepted as separate, sexually dimorphic species. The females of the two forms are abundantly distinct, but no satisfactory separation character for males has ever been described (see Hinton's monograph[1]).

P. hirtellus has been maintained in culture at the Pest Infestation Laboratory for many generations and abundant material of both sexes has been available for study. Attempts to obtain cultures of *P. latro* by similar methods have led to the discovery that this is a parthenogenetic form of unusual type.

Through the kind co-operation of the London area inspectors of the Ministry of Agriculture, Fisheries and Food, a few living female *latro* were obtained during November 1953. These were cultured on a mixture of equal parts of fishmeal and wheatmeal with about 5 per cent dried yeast, at 25° C. and 70 per cent relative humidity, and eventually seventeen larvæ were obtained. From these, seventeen adults were reared, all of which proved to be female *latro*. They were separated into two groups of seven and ten individuals, respectively. The former were kept unmated until death (a matter of several months), whereas the latter were provided with twelve fresh males from a culture of *hirtellus*. No progeny resulted from the virgin females, but the mated females produced twenty-one larvæ. Again exclusively female *latro* were reared.

On the advice of Mr. R. W. Howe, of the Pest Infestation Laboratory, the third generation was cultured (with *hirtellus* males) at 20° C., a temperature which he has found to be the optimal for oviposition in several species of ptinids. This resulted in a very large culture, and between 1,500 and 2,000 adults, all female *latro*, were reared. Many thriving cultures are now being maintained under these conditions, but further experiments with virgin females have again failed.

The biological findings strongly suggest that female *latro* reproduce by parthenogenesis, and this is supported by the extreme uniformity of the reared individuals. However, mating, which takes place very readily with male *hirtellus*, appears to be essential, for we have never succeeded in rearing from virgin *latro*. Under crowded conditions, unmated females will lay a few eggs, but these do not hatch and soon collapse. Preliminary experiments indicate that the mating reaction between female *latro* and male *P. fur* L. or male *P. pusillus* Sturm is weak. Comparatively few instances of attempted copulation have been observed, although a small number of female *latro* progeny have resulted from the latter cross. Thus, on balance, it appears that *hirtellus* and *latro* comprise a single polymorphic species.

One of us (A. R. S.) has investigated the problem from the cytological point of view. The work is at present incomplete, but the results to date show that the male and female *hirtellus* have a diploid constitution ($2n = 18$); female *latro* has 27 chromosomes and is therefore a triploid. Maturation is normal in the male, sperms having $8 + X$ or $8 + Y$. The maturation spindle forms in the unlaid egg; in *hirtellus* reduction occurs, in *latro* the triploid number is retained. Insemination of the *latro* female is essential for the development of the egg but, since the egg does not show reduction, the sperm can play no part in regulation of the chromosome number.

In order to investigate the role of the sperm, *hirtellus* males were sterilized at Harwell by exposure to γ-radiation and mated with *hirtellus* and *latro* females. Copulation was normal but resulted in large-scale production of non-viable eggs. Thus not only is insemination of the *latro* female essential for oviposition but also the sperm must play some part in initiating activation of the egg. Full-length sperms have been observed in the developing *hirtellus* egg, but we are not yet certain that the sperm enters the *latro* egg. Biological and cytological evidence indicates that in *Ptinus latro* we are dealing with thelytokous parthenogenesis of a particular type—either gynogenesis or some form akin to it in which the sperm plays an even more restricted part.

In Coleoptera thelytokous parthenogenesis occurs as a normal method of reproduction only in the Curculionidae[2]. So far as we are aware, parthenogenesis of the type described here is unique within the order. Further details of the biological, taxonomic and cytological aspects of our work will be given in other publications.

Estimation of Numbers of *Nitrosomonas* in Soil and Culture

Attempts to estimate the numbers of nitrifying organisms in soil have usually been made by some form of dilution technique involving culture of the dilutions in liquid media in tubes (see ref. 1). The number of dilutions, and of replicate tubes at each dilution, that are necessary to give reliable estimates, makes this method extravagant of material and time. Singh[2] developed a dilution method for estimating numbers of Protozoa in soil suspensions, in which Petri dishes, each containing a number of replicate disk cultures on agar, effected a great saving in both these respects. Attempts were made to adapt this method to estimating numbers of *Nitrosomonas*. The medium used was prepared from the following solutions, separately sterilized, and mixed in the proportions of 2·0 ml. each of solutions (I) and (II) to 12·0 ml. of (III).

Solution I: NaCl, 0·2 gm.; $MgSO_4,7H_2O$, 0·05 gm.; Na_2HPO_4, 1·2 gm; KH_2PO_4, 0·6 gm.; $NaHCO_3$, 0·1 gm.; $FeSO_4,7H_2O$, 1·0 mgm.; $MnSO_4,4H_2O$, 1·0 mgm.; tap water to 100 ml.
Solution II: 0 8 per cent w/v $(NH_4)_2SO_4$ in distilled water.
Solution III: 2·5 per cent w/v 'Difco' Bacto-Agar, washed for 24 hr. in running tap water.

Silica gel was found unsuitable owing to the tendency for water to form a film on the surface. This agar medium was used in the following dilution technique, which was tested both with soil and with liquid cultures of *Nitrosomonas*. Eight glass rings (20 mm. inside diameter, 7–8 mm. deep) are arranged in a Petri dish, and heat sterilized. To each ring 1·0 ml. of the medium is added aseptically, the medium being held at 52–55°. On meeting the cold dish and ring, the agar gels and does not spread beyond the ring. To ensure this, the edges of the rings in contact with the dish must be ground smooth. In this way, eight discrete disks of agar can be produced per plate. Preliminary experiments showed that nitrite diffused rapidly through the agar, so that the separate disks must not be connected with an agar film. From a 1 : 5 suspension of the soil or dilution of the culture, further two-fold dilutions are made to give a final dilution of 1 : 81,920. One Petri dish is used per dilution, 0·05 ml. of which is applied to each of the eight disks. After inoculation the dishes are placed in MacIntosh and Fildes jars which are flushed for periods of 2 hr. daily with air drawn through 50 per cent v/v sulphuric acid followed by 1 per cent w/v sodium bicarbonate, in order to remove oxides of nitrogen found to be present in the laboratory atmosphere. After incubation at 18–22° for 21 days, the cultures are tested for nitrite by adding to each disk two drops each of sulphanilic acid solution (0·6 per cent, w/v, in 30 per cent, v/v, acetic acid), and N-(1-naphthyl) ethylene diamine dihydrochloride (0·1 per cent, w/v, in 3 per cent, v/v, acetic acid). These solutions must be stored in the dark. An intense red coloration indicates the presence of nitrite. As a check, uninoculated plates are also incubated. The number of organisms per ml. of original suspension may then be computed by applying Fisher's method of 'negative plates'[3]. Singh[2] has prepared a table from which the number of organisms per ml. of original suspension can be obtained directly when the previously mentioned dilution series and eight replicate 0·05 ml. inocula per dilution are used. Two populations are significantly different in numbers if the number of 'negative' cultures varies by ± 8 or more, that is, + 100 per cent, − 50 per cent.

To test this technique, a suspension in saline of *Nitrosomonas*, previously counted in a hæmocytometer, was used. A dilution series of this suspension was applied to the disks and a parallel series inoculated into test-tubes, each containing 5 ml. of medium without agar, with eight replicate tubes at each dilution. Parallel tests were also carried out in which the counted suspension was added to sterilized Rothamsted soil and serial dilutions made from a suspension of it. The 'recovered' numbers estimated

Table 1

	Hæmocytometer count	Estimated numbers	
		Agar disk method	Test-tube method
Experiment 1			
Saline control	500,000	311,000	650,000
Soil	500,000	5,080 (1 per cent recovery)	931,000
Experiment 2			
Saline control	500,000	380,000	931,000
Soil	500,000	41,400 (8 per cent recovery)	520,000

All figures represent number of organisms/gm. soil or ml saline.

from the disk and tube dilutions obtained in two experiments are given in Table 1.

Both disk and tube methods gave a satisfactory 'recovery' of numbers from the suspensions in saline, having regard to the limited accuracy of a dilution method. The test-tube method also gave satisfactory recovery from the soil suspension; but with disks, recovery was only 1 per cent and 8 per cent in the two experiments.

A recovery test was then made in unsterilized soil to see whether sterilization of the soil had produced substances harmful to growth. A counted suspension of *Nitrosomonas* was added to fresh soil. Numbers were then estimated by the disk method from this soil and from an uninoculated control soil. In a later experiment, a similar test was made with the tube method. The results (Table 2) again show that the fresh soil has interfered with the recovery of added numbers in the disk method, but not with the tube method.

Table 2. RECOVERY OF *Nitrosomonas* FROM UNSTERILIZED SOIL

	No. of organisms added, per gm. soil	No. of organisms estimated, per gm. soil
Agar disk technique		
Uninoculated soil	0	6,040
Inoculated soil	600,000	22,400 (3·75 per cent recovery)
Test-tube technique		
Uninoculated soil	0	59,000
Inoculated soil	500,000	729,000

These results point to some factor introduced by the soil which interferes with growth on agar disks, but not in test-tubes, where it is perhaps diluted out. The nature of this factor will be further investigated.

Nucleus and Spindle of *Bacillus megaterium* in Fission and Sporulation

IN a recent communication in *Nature*, Yuasa[1] ontends that the 'side-body' of the spores of *Bacillus megaterium* is identical with the spindle of the dividing yeast nucleus, and acts as such in a mitotic division of the bacterial nucleus.

This is quite unacceptable for the following reasons: 1) The theory of a mitotic division in *B. megaterium*, advanced by DeLamater[2], so far from being regarded even as a problematical alternative to the now classical concept of the bacterial nucleus[3], has been very severely criticized on both theoretical and practical grounds by leading authorities in all parts of the world[4]. (2) The 'side-body' has now been proved conclusively to be an artefact caused by partial ejection of the turgid nuclear contents of the spore[5]. (3) The 'large-body' in the vegetative bacillus, which Yuasa claims to be identical with the 'side-body', appears from his diagrams to represent the polar aggregate of basophilic material associated with the growing tip of the cell[6].

The apparent contention of Yuasa that the authors whom he quotes themselves equate this structure in the sporing bacillus with the 'side-body' (that is, the ejected nucleus) of the spore is without foundation.

Use of Capacity Measurements for the Study of Oxide Films on Metals

ESTIMATES of the thickness of oxide films on metals have long been made by immersion in an electrolyte and measurement of the capacity of the condenser formed by the film as dielectric[1]. It has, however, been pointed out by E. Huddle (private communication) that such measurements are liable to error if the film contains cracks, for these permit the electrolyte to approach closer to the metal/oxide interface. This should cause the 'capacity' thickness to be less than that derived from measurements of gain of weight, for example. A rise in the capacity of anodized films under condition of breakdown has been reported by Young[1].

This behaviour has been turned to advantage in the examination of the films formed in the corrosion of zirconium alloys. When the latter are exposed to water at about 300° C., the rate of corrosion, as measured by the gain of weight, at first falls with time. At a certain stage, called 'breakaway'[2], the film on most alloys becomes less protective, and the rate changes to a constant, higher, value. All the specimens examined in these experiments had suffered breakaway, except those of the alloy 'Zircaloy 2' (1·5 per cent tin, 0·13 per cent iron, 0·05 per cent nickel, 0·12 per cent chromium, balance zirconium), which is very resistant to corrosion.

Specimens of the alloys detailed in Table 1 were pickled in a solution containing 45 c.c. nitric acid (concentrated), 5 c.c. hydrofluoric acid (48 per cent solution), 50 c.c. water and then weighed. After exposure to water at 325° C. for periods up to about 500 hr. they were reweighed, wires were attached to them, and they were waxed, leaving 1 cm.^{2} (apparent

area) bare. They were immersed in $N/1$ sulphuric acid, together with a platinized platinum electrode, and the impedance of this cell was measured at 1,000 c./s. using a Wien-type bridge with Wagner earth. Arrangements were made to keep the specimens at a constant, arbitrary, potential of + 1·00 V. (saturated calomel). The a.c. voltage impressed on the cell was not more than a few centivolts (r.m.s.). The cell impedance was expressed as a resistance and capacity in series. The observed capacity values were much smaller than that of the double-layer capacity on metal surfaces, so that the latter, and the capacity of the platinum electrode, which are both in series with the film capacity, could be neglected. The resistance represents that of the electrolyte, which was kept low by the use of a solution of high conductance, together with a contribution from the oxide film which has recently been more fully treated by Young[1].

The capacity results are given in Table 1, together with their reciprocals (which are a measure of 'capacity' thickness) and the gain of weight. Since adherent films were formed in all but two cases, the latter give valid measures of 'weight' thickness. The comparison of 'weight' and 'capacity' thickness, obtained by evaluating $1/C.W$ (C in microfarads/cm.^{2}, W in mgm./cm.^{2}), gives figures which sharply discriminate between 'Zircaloy 2' and the less resistant alloys, suggesting that the films on the latter are considerably cracked whereas those on 'Zircaloy 2' contain few cracks, or, possibly, no cracks at all. This view is supported by the dependence of capacity on time. With 'Zircaloy 2' the capacity quickly settled to a value which remained steady for many hours ; but with the other materials an upward drift began when the specimen was immersed in the electrolyte and was still perceptible 24 hr. later. This is consistent with the slow penetration of the electrolyte into a cracked film. That it is possible, under more drastic conditions, to reduce the 'soundness' of the film on 'Zircaloy 2' is shown by the results for a specimen exposed to superheated steam at 500° C. and 1 atmosphere pressure. This specimen also showed an upward drift of capacity with time.

Some capacity measurements were also made at other frequencies, 60–5,000 c./s. The dependence of resistance and capacity on frequency for both 'Zircaloy 2' and other alloys conformed approximately to the relations derived by Young[1] for crack-free films.

If the films on 'Zircaloy 2' are assumed to be entirely crack-free, their theoretical capacities may be calculated approximately, using Charlesby's[3] value of 27 for the dielectric constant and a density of 5·7 for zirconium oxide. Then $C = 3{\cdot}5 \times 10^{-3}\,\sigma^2/W$ μF./apparent cm.^{2} (σ is true area/apparent area). If the calculated and observed capacities of the 520-hr. film are equated, σ is found to be about 1·5. Adams, Maraghini and Van Rysselberghe[4] reported σ to be $2{\cdot}1 \pm 0{\cdot}2$ for abraded zirconium and, in comparison with this, a value of 1·5 for a bright pickled surface seems reasonable.

These measurements suggest that after 'breakaway' the oxide film on zirconium alloys consists of an outer cracked portion into which water can penetrate, and an inner, crack-free portion which controls the rate of corrosion.

The results obtained with zirconium alloys suggest capacity measurement as a useful method of studying the protective character, as distinct from the thickness, of oxide films formed by corrosion and oxidation.

The Standard of Length and the Standard of Time

The interesting communication in *Nature* o December 24, p. 1230, from Dr. G. M. Clemence[1], under the title "Definition of the Second of Time", has suggested to me some comments.

First of all, there is, in the first line of the secon column, a slight error : the number of microns i 1 metre cannot be subject to experimental determina tion. The micron, which is sometimes called th 'micro-metre', is, by definition, the millionth part of the metre. What is meant is the 'angström', A. the angström being related to wave-length, by th expression A. = $\frac{1}{6438{\cdot}4696}$ wave-length of the re cadmium line in standard air.

However, precautions were taken to avoid havin two units of length, and the angström will remai what it is nowadays, equal to 10^{-10} m. (personally I hope it will disappear). Indeed, we know that (du to what is unquestionably a lucky chance) the averag of the values obtained by various experimenters since the work of Benoît–Fabry–Perot, for the wave length of red cadmium in standard air is exactl 0·643 846 96μ, the very value which was given b Benoît–Fabry–Perot.

Now, the Comité International des Poids et Mesures has already adopted a Recommendation of its Comité Consultatif pour la Définition du Mètre, which reads as follows: "In view of giving the unit of length a continuity as perfect as possible, when going to the contemplated definition, it is recommended to work out the latter, by using, as an intermediate step, the value $0{\cdot}643\ 846\ 96 \times 10^{-6}$ m. for the wave-length of the red-cadmium line, as specified by the 7th Conférence Générale des Poids et Mesures".

This means that, to the limit of accuracy which may be reached at present (and I wish to add, to the limit of accuracy which can be reached by the present prototype line standard), the metre, defined by means of the wave-length, will be strictly equal to the present metre defined by means of the platinum–iridium prototype. The standard will have been changed, but the unit will not have been changed and this unit will remain the same for all users, as the one and only unit of length, but defined by means of a wave-length.

It will be the same—at least I hope so—for the unit of interval of time. When we are assured of the permanency of an atomic frequency, and physicists, in agreement with astronomers, take such a frequency as a standard, then they will do it so as to determine exactly the number N, for an interval t such that:

$Nt = 1/31\ 556\ 925{\cdot}974\ 74$ tropical year 1900.0 = the second, the tropical year 1900.0 being derived from the tropical year for the time being by applying corrections always known. Until this clock is confirmed to be permanent (perpetual and endless), we shall have to consider that atomic frequency is just a wonderful interpolation tool—or, if we like, a recorder of the standard—but not as a standard itself. In the same manner, the wave-length is still a recorder of the metric unit. It would be nonsense to have one standard for short times and another one for very long times.

The standard of interval of time will have been changed; it will be t instead of the tropical year 1900.0 (in practice, the tropical year of the time being); but the unit, for everyone whatever his branch of learning may be, will be exactly the same: the 'second', the one and only unit of time. The change of standard would not, of course, prevent physicists (or astronomers), after the changes have been made, from carrying out very interesting experiments, in order to determine the possible slight variations of old standards, expressed in the new units recognized as absolute invariants.

It does not appear that the simultaneous existence of two units extremely close to each other has serious drawbacks. We have already experienced those drawbacks with units of volume (cubic decimetre and litre). But we are still feeling those drawbacks and we hope to remove them by means of the new French law which is now in preparation.

It is true that the unit of length and the unit of time will no longer be independent. But I think we can leave it to the third generation of our successors to adjust the definitions of the metre and the second with the sufficiently accurate value that they will have then been able to obtain for the velocity of light. It will be, as it is even now, a question of accuracy.

What follows in Dr. Clemence's communication is a matter of astronomy, and there I declare myself incompetent.

Dr. Clemence has seen the present communication, and desires me to say that he regrets his error in confusing the micron with the angström, while still asserting the principle of his argument. Further, he agrees completely with my views, with the exception of the question of the desirability of changing the definition of the metre, which he has not studied sufficiently to form a competent opinion.

Thermal Conductivity of Solid Argon at Low Temperatures

VALUES which are fairly reproducible for the thermal conductivity K of an inert gas solid, argon, have been obtained over a range of temperatures from 2° to 25° K., corresponding to temperatures $\theta/40$–$\theta/3$ since the Debye characteristic temperature θ for solid argon is about 80° K. These measurements were made by filling a thin-walled 'Inconel' tube of diameter 0·5 in. and length about 3 in. with argon at a temperature of approximately 78° K., through a capillary tube. During filling, the gas pressure was maintained above the triple-point pressure to ensure that liquid argon was produced in the specimen tube, and this gradually solidified from the bottom and from the walls of the tube to produce a homogeneous solid. The 'Inconel' tube, for the thermal conductivity of which small corrections were applied to the results, was mounted in a thermal conductivity cryostat described previously by White and Woods[1].

As shown in Fig. 1, the thermal conductivity of solid argon from the lowest temperatures rises approximately as T^2 to a maximum value of 0·045 watts/cm. deg. at 7° K. and then decreases. Above 15° K., the conductivity may be approximately expressed by $K \simeq 0{\cdot}28/T$ watts/cm. deg. It is interesting to compare this latter relation with the formula proposed by Dugdale and MacDonald[2] for

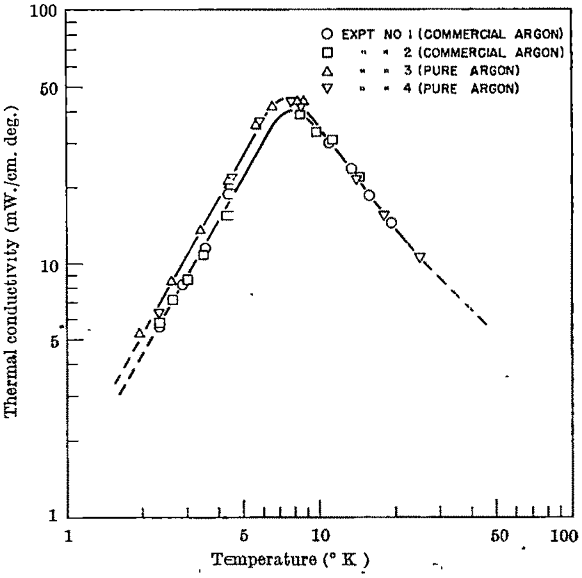

Fig. 1 Thermal conductivity of solid argon at low temperatures

the lattice thermal conductivity of a simple dielectric solid in the temperature region ($T \sim \theta$), where anharmonic coupling between the lattice waves is the dominant cause of thermal resistance, namely,

$$K = \frac{1}{3}\, v.C.A_0/\alpha\gamma T$$

Substituting experimental values for the specific heat per unit volume C, the lattice constant A_0, the velocity of sound v, the thermal expansion coefficient α[3], and a probable value of $\sim 2{\cdot}5$ for the Grüneisen constant γ[4], $K \sim 0{\cdot}4/T$ watts/cm. deg. is obtained.

Thermal resistance due to the scattering of lattice waves by grain boundaries, static imperfections, etc., has been discussed by Berman[5] and Klemens[6]. The temperature dependence of our results and the small magnitude of the conductivity at temperatures below 6° K., suggesting a mean free path $\sim 10^{-4}$ cm., seem to indicate that the dominant mechanism producing thermal resistance below the maximum is that of scattering by dislocations.

Previous measurements by Webb and Wilks[7] on solid helium indicated that at very low temperatures $K \propto T^{2{\cdot}3}$ and just above the maximum in the so-called umklapp region $K \simeq A\, e^{\theta/bT}$, where $b \simeq 2$. We suggest that in the case of argon, the conductivity in this region is considerably reduced by the presence of dislocations or other static imperfections, which would mask such temperature dependence. However, it is intended to continue this research and extend it to other inert gas solids, and a fuller account of the methods and results will be published elsewhere.

Dependence of the Elastic Properties of Cadmium on Temperature

Yousef and Kamel[1] have studied Young's modulus and the internal friction of cadmium as a function of temperature at 50 cycles per second. Young's modulus vs. temperature curve of polycrystalline cadmium shows a sharp break at about 80° C., while the same metal in the single-crystal form behaves in a normal manner. This suggests that it may be due to stress relaxation at grain boundaries. One would then expect a higher transition temperature at higher frequencies. The same behaviour would also be expected in the case of the rigidity modulus. The variation of the elastic constants of polycrystalline cadmium with temperature at 100 kc./s. has therefore been studied.

Specimen rods of rectangular and cylindrical cross-sections are cut from 99 per cent pure cadmium supplied by B.D.H., Ltd. Natural frequencies, longitudinal and torsional, of the specimens are measured as a function of temperature, using the composite oscillator method[2]; the results are presented in Fig. 1. The square of the natural frequency is taken as a measure of the related elastic constant. A sudden change in the gradient of (frequency)^2 vs. temperature curves occurs at 130° C. Bordoni and Nuovo[3] measured the velocity of longitudinal waves in cadmium as a function of temperature at 9 kc./s. Their results show a transition at 127° C. Thus the transition temperature is dependent on frequency and increases with it.

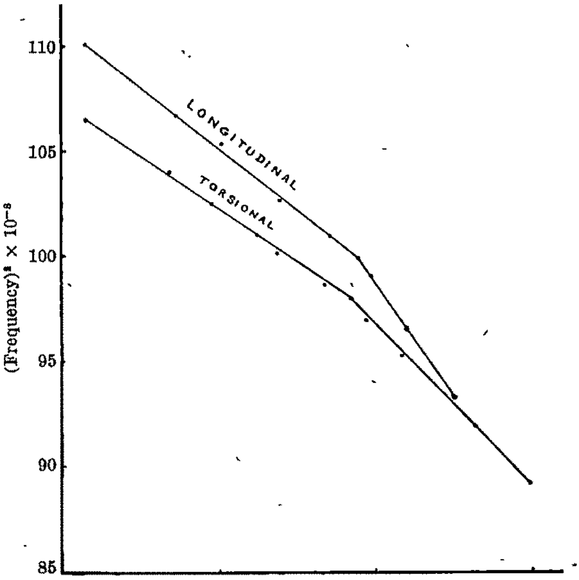

Fig. 1

The activation energy associated with the above phenomena has been calculated using the transition temperatures from elasticity data at 50 c./s. and 100 kc./s. and is found to be 40,000 cal./mole. This may be regarded as in fair agreement with the value, 32,000 cal./mole, calculated from internal friction data by Yousef and Kamel.

Absence of the transition phenomena in the single crystal and its dependence upon frequency in polycrystalline cadmium proves that the mechanism involved is stress relaxation at the grain boundaries.

I thank Prof. S. Bhagavantam for his guidance and encouragement during the course of this work.

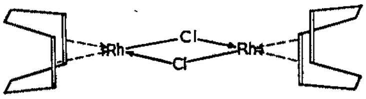
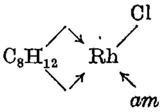
Olefin Complexes of Rhodium

Stable olefin complexes are formed only by metals near the end of each transition series in the Periodic Table, and these metals form a triangle in the Table, Cu(I) ; Pd(II), Ag(I) ; Pt(II), {Au(I)}, Hg(II). It is characteristic of the complex chemistry of metals inside the triangle that they tend to form stronger complexes with ligands containing donor atoms from the third or subsequent rows of the Periodic Table than with the corresponding ligands containing donor atoms from the second row (counting hydrogen and helium as the first row)[1]. This rule of co-ordination chemistry also extends to metals bordering on the 'olefin-complex triangle', especially to the metals to the left of the triangle. It seems reasonable to expect, therefore, that the triangle might eventually be extended to the left in the Periodic Table. With this object in view, we are attempting to obtain olefin complexes of cobalt, rhodium, iridium, iron, ruthenium and osmium, using the strongly chelating di-olefin, 1 : 5-*cyclo*-octadiene, and are now reporting briefly a series of rhodium complexes. When an ethanolic solution of rhodium chloride ($RhCl_3$) to which 1 : 5-*cyclo*-octadiene (C_8H_{12}) has been added is boiled under reflux, a very stable yellow crystalline solid of the composition $C_8H_{12}RhCl$ is deposited. It is diamagnetic and dimeric, and so must have the chloro-bridged structure (I), in which the metal will have square planar (*dsp*^{2}) co-ordination. When it is treated with an amine, *am*, the bridge is split to give mononuclear complexes of the type (II). Derivatives of $(C_8H_{12})_2Rh_2Cl_2$ (I) in which the chlorine atom is replaced by other univalent acid radicals, for example, bromine, iodine and SEt, were prepared. The stability of the derivatives falls rapidly in the order Cl > Br > I > SEt, as would be expected, since this is the order of increasing *trans*-effect of these acid radicals.



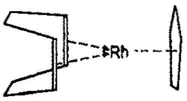
(I) Proposed structure of $(C_8H_{12})_2Rh_2Cl_2$. The dotted lines representing bonds between the olefinic double bonds and the metal are intended to imply a scheme of bonding such as has been suggested in the ion $[C_2H_4PtCl_3]^-$ (see ref. 4)



(II)

A novel derivative $C_8H_{12}RhC_5H_5$ (III), in which he metal atom is co-ordinated by nine carbon atoms, as been prepared by treating (I) with *cyclo*pentaienyl sodium. It is a beautifully crystalline solid, nelting at 108° C. without decomposition, is mononeric, and is readily soluble in organic solvents. It is nteresting because very few types of purely hydroarbon co-ordination compounds are known, and ntil recently those few, for example, $\{(CH_3)_4Pt\}_4$ nd the metal bis*cyclo*pentadienyls, have all contained ydrocarbons as anionic ligands. Very recently, 'ischer[2] has described some purely hydrocarbon comlexes which contain only uncharged hydrocarbon gands, for example, dibenzenechromium, $(C_6H_6)_2Cr$. n the complex (III) we have both uncharged and nionic hydrocarbons as sole ligands in a metallic comlex. The compound is analogous to $(CO)_2CoC_5H_5$ [3], which the cobalt atom has been replaced by hodium and the two carbon monoxide molecules by he di-olefin.

Attempts to prepare cationic and anionic olefin omplexes of rhodium, such as $[C_8H_{12}Rh\,am_2]^+$ and $C_8H_{12}RhCl_2]^-$, indicate their possible existence; ndeed, a pure salt $[C_8H_{12}Rh\{(NHEt)_2C_2H_4\}]\,[BPh_4]$ as been isolated, but all the anionic complexes which e have tried to prepare up to the present have proved nstable.



(III) Proposed structure of $C_8H_{12}RhC_5H_5$. The bond between the rhodium atom and *cyclo*pentadienyl anion will be of the same type as occurs in ferrocene, but its exact nature is still controversial (for example, see Pauson, *Quart. Rev.*, 9, 391 (1955) and references quoted therein)

It is interesting that Rh(I), which is isoelectronic with Pd(II) but not of common occurrence in rhodium compounds, should occur in the olefin complexes. In Rh(I) the rhodium atom is in the highest valency state, where all its *d*-orbitals can be filled and a vacant *p*-orbital remain. The dimagnetism of $(C_8H_{12})_2Rh_2Cl_2$ (I) confirms that electronic arrangement. This suggests that the vacant *p*-orbital is necessary to provide sufficiently strong dative π-bonding (by *dp*-hybridization) to bind the olefin to the metal[4].

Full details of this work and a discussion on the general structure of olefin complexes will appear in due course elsewhere We are greatly indebted to Imperial Chemical Industries, Limited, Billingham Division, for a gift of the *cyclo*-octadiene used in the above investigation.

Boundary Problems in the Sedimentation and Electrophoresis of Complex Systems in Rapid Reversible Equilibrium

Many problems of current interest, for example, the dissociation of nucleoproteins, the reaction of antigens with antibodies, and the combination of proteolytic enzymes with inhibitors, to mention only a few, are at first sight open to attack by the conventional methods of sedimentation and electrophoresis. To a greater or less extent, however, in all these instances, instead of the underlying process of differential transport leading to a simple resolution of the components at the boundaries between solution and solvent, the situation is confused by re-equilibration as the reactants and products tend to be separated from one another. This effect has been much discussed[1–3], but an exact theoretical treatment of the general case seems to be prohibitively difficult if all factors, including the finite rate of approach to equilibrium and the simultaneous spread of the boundaries through diffusion, are taken into account. Even so, Ogston and Field[3] have calculated the form of the sedimentation boundary by numerical methods for the particular case of the dissociation of human hæmoglobin.

In these circumstances, it is a considerable help to have a treatment for an idealized system in which diffusion is ignored, and in which equilibrium is taken as being attained instantaneously. The interpretation of experiments with actual systems can then be carried out by analogy. This approach proved useful recently[4] for interpreting the sedimentation of α-chymotrypsin[5] and mercuripapain[6] under conditions where reversible polymerization occurs, and it is now extended to the more general case of two substances, A and B, reacting reversibly to form a third, C, in accordance with the equation $A+B \rightleftharpoons C$.

Consider a boundary between solution and solvent after transport by electrophoresis or sedimentation has occurred for a time t sec. Assume that the boundary is sharp at $t = 0$; and measure distance, x, from the initial position of the boundary, and in the direction of the solution. Let the respective velocities of A, B and C be v_A, v_B and v_C in the direction of x, and let the molar concentrations of A, B and C be a_0, b_0 and c_0 in the unchanged body of the solution, and a, b and c at x. Equilibrium will be assumed to be governed by the equation $a.b = k.c$, where k is a constant.

The rate of change of concentration with time at any point in the boundary where A, B and C co-exist is the combined result of the migration and the reaction of each of the species. Since mass is conserved, it follows that:

$$\frac{\partial a}{\partial t} + v_A \frac{\partial a}{\partial x} = \frac{\partial b}{\partial t} + v_B \frac{\partial b}{\partial x} = -\frac{\partial c}{\partial t} - v_C \frac{\partial c}{\partial x}$$

It will be shown elsewhere that these partial differential equations can be solved to give

$$a = \frac{k}{\lambda - 1} \cosh^2 \frac{\varphi}{2} \left\{ 1 - \frac{\Phi - \varphi}{\sinh \varphi} \right\}$$

$$b = \frac{k}{\lambda + 1} \sinh^2 \frac{\varphi}{2} \left\{ 1 + \frac{\Phi - \varphi}{\sinh \varphi} \right\}$$

$$c = \frac{ab}{k}$$

where φ is a convenient parameter defined by

$$\cosh \varphi = \frac{2(v_C - v_A)(v_C - v_B)}{(v_A - v_B)(v_C - x/t)} - \lambda$$

$$\text{and } \lambda = \frac{2v_C - (v_A + v_B)}{v_A - v_B}$$

Φ is a constant determined by a_0, b_0 and c_0. The concentration gradients $\partial a/\partial x$, $\partial b/\partial x$ and $\partial c/\partial x$, which determine the schlieren patterns seen during optical analysis of the boundaries, are readily obtained by differentiation of the respective expressions for a, b and c.

The detailed application of these equations cannot be discussed here; but to give an indication of their use, the shape of the sedimentation boundary has been worked out for an example in which, for illustration, a_0, b_0 and c_0 and k have been given the respective values of 2·0, 1·0, 1·0 and 2·0 moles/litre × 10^4; and v_C, v_A and v_B the respective values of 14, 10 and 8 Svedberg units.

The boundary is found to keep its essential shape and merely to stretch out with time. It can therefore be represented by a 'reduced' form in which concentration, or alternatively the derivative of concentration, is plotted as ordinate against sedimentation coefficient as abscissa (see Fig. 1).

Dotted lines show the contribution each constituent would make to the boundary if no re-equilibration occurred. They demonstrate how completely the form of the boundary is changed by re-equilibration. Among the points to notice are: (1) the value of the concentration of B that would be deduced from the slow peak at $S = 8·0$ units is $0·26 \times 10^{-4}$ compared with the true equilibrium value of $1·0$ $10^{-4}\ M$; (2) although two-thirds of A is uncombine there is no peak corresponding to the sedimentatio constant of A at $S = 10$; (3) the broad peak stretch ing from $S = 10·5$ to $S = 12·0$ suggests the presen of two complexes; (4) there is no peak at $S = 1$ in spite of the presence of complex having th sedimentation constant.

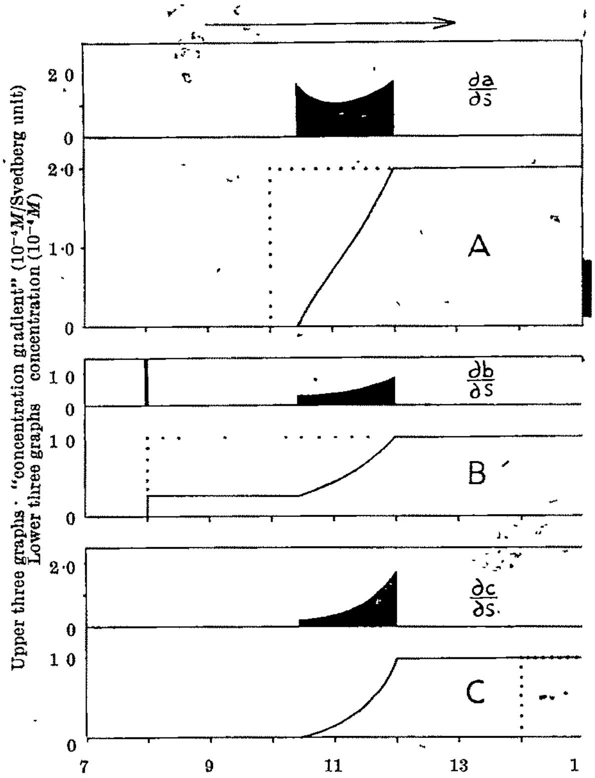

Fig. 1. Sedimentation of a complex molecule C in equilibrium with its components A and B. ———, Calculated concentration assuming re-equilibration without diffusion. Blocked areas represent contributions to the schlieren pattern (refractive index factors not included) . . . . ., calculated concentration assuming no re-equilibration or diffusion

In this example, therefore, an interpretation the sedimentation pattern which neglected the effe of re-equilibrium would lead to a wrong estimate the nature of the complex present and of the co centrations of the uncombined constituents.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, May 7

Royal Society of Medicine, Experimental Medicine and Therapeutics Section (at 1 Wimpole Street, London, W 1), at 2 p.m —Annual General Meeting; followed by a Symposium on "Anti-tumour Agents"

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m —Annual General Meeting, Mr C F. Floyd "An Introduction to Microwaves and Waveguide Transmission".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p m —Prof. T. S. Simey. "Class Conflict and Social Mobility". (First of three Cantor Lecures on "Some Recent Studies of Sociology".)

Society of Chemical Industry, London Section (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 15 p m.—Annual General Meeting; Dr. W. P Grove "The Radiochemical Centre at Amersham".

Tuesday, May 8

Wright-Fleming Institute of Microbiology (at St. Mary's Hospital Medical School, London, W 2), at 5 p m —Prof L Pillemer (U.S A) · "The Nature of the Properdin System" (Almroth Wright Lecture).

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N W.1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p m.—Mr J. Bell "Ship Stabilization · Automatic Controls, Computed and in Practice".

University College, London (in the Anatomy Theatre, Gower Street, London, W C 1), at 5 30 p m.—Dr. Luther H Evans "Certain International Aspects of Librarianship".*

Tuesday, May 8—Thursday, May 10

Perkin Centenary Celebration (at the Royal Institution, Albemarle Street, London, W.1).

Tuesday, May 8

At 3 p m.—Prof. John Read, F.R.S . "The Life and Work of Perkin".

Wednesday, May 9

At 11 a m —Mr Clifford Paine · "The Development of the Dyestuffs Industry".

At 3 p.m.—Mr. J. G. Evans: "The Tinctorial Arts To-day".

Thursday, May 10

At 11 a.m —Sir Alexander R. Todd, F.R.S "The Development of Organic Chemistry since Perkin's Discovery"

Wednesday, May 9

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 10 a m.—All-Day Section Discussion on "Supersonic Flight".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C 2), at 2 30 p m.—The Right Hon. the Earl of Halsbury. "Automation"

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5 30 p m.—M. P. S. Hirtz (Paris) "Recent Oil Development in France".

Newcomen Society (in the Lecture Theatre of the Science Museum, South Kensington, London, S.W.7), at 6 p m —Dr. Joseph Needham, F.R.S. "Iron and Steel Production in Ancient and Medieval China". Second Dickinson Biennial Memorial Lecture.)

Society of Chemical Industry, Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 6 15 p.m —Annual General Meeting 6.45 p.m.—Dr. Norman C. Wright · "National Taste and National Waste"

Thursday, May 10

Royal Aeronautical Society, Graduates' and Students' Section (at 4 Hamilton Place, London, W.1), at 7.30 p m.—Sir Frederick Handley Page "Some Thoughts on Present-Day Aircraft and the Future".

Friday, May 11

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4 30 p m —Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at) p.m —Prof. H S. W. Massey, F.R.S. · "The Exploration of the Upper Atmosphere".

Saturday, May 12

British Psychological Society, Social Psychology Section (at Bedford College, Regent's Park, London, N.W.1), at 2.15 p.m.—Symposium on "Personality and its Social Setting".

British Psychological Society (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C 1), at 2.30 p.m.—Dr J O Wisdom: "Models for the Mind-Body Relationship".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Organic Chemist (with a good honours degree (or equivalent) in chemistry and preferably experience in analytical technique) in the Coal Survey Laboratory in Sheffield, for investigations of the complex character of coals—National Coal Board, Staff Department, Hobart House, Grosvenor Place, London, S W.1, quoting SS/257 (May 11).

Assistant Lecturer (Grade B) in Physics at Brighton Technical College—Director of Education, County Borough of Brighton Education Committee, 54 Old Steine, Brighton 1 (May 12).

Assistant Lecturer (with a university degree or diploma in horticulture, and a sound knowledge of practical horticulture) in Horticulture—Principal Agricultural Officer, Lancashire County Institute of Agriculture, Hutton, near Preston (May 12).

Junior Chemist (with a B.Sc. degree or an A.R.I.C qualification) on the Engineer's Staff, for analytical and experimental work concerned with sewage purification and sludge disposal—Clerk to the Board, Birmingham Tame and Rea District Drainage Board, Clerk's Office, 115–117 Colmore Row, Birmingham 3 (May 12).

Lecturer or Assistant Lecturer in Physiology—The Registrar, The University, Sheffield (May 12)

Lecturer (with at least a good honours degree and capable of teaching to B Sc. (special) or A.R.I.C. standard, and preferably with industrial, teaching and/or research experience) in Physical and/or Inorganic Chemistry—The Principal, Stockport College for Further Education, Wellington Road, South Stockport (May 12).

Principal Lecturer in Applied Chemistry, Senior Lecturer in Radar and Telecommunications or Electronic Instrumentation, Senior Lecturer in Engineering Physics, Senior Lecturer or Lecturer in Mechanical Engineering: Applied Thermodynamics, Senior Lecturers or Lecturers (2 or more) in Electronics, Senior Lecturer or Lecturer in Chemistry, and a Senior Lecturer or Lecturer in Physics; at the Royal Military College of Science, Shrivenham—Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting Ref. No. S.4584/56/8 (May 12).

Assistant Lecturer (preferably with special qualifications and experience in poultry husbandry) in Animal Husbandry at the School of Agriculture, Sutton Bonington, near Loughborough—The Registrar, The University, Nottingham (May 19).

Lecturer in Electrical Engineering—The Registrar, The University, Sheffield (May 19).

Lecturer in Mathematics—The Secretary, The University, Aberdeen (May 19).

Lecturer (with a special qualification in applied mathematics, and preferably an interest in fluid dynamics) in Mathematics—The Registrar, The University, Manchester (May 19).

Assistant Lecturer and a Lecturer in the Department of Applied Mathematics—The Registrar, The University, Liverpool (May 23).

Lecturer (with a special qualification in organic chemistry and undertaken independent research in some branch of this subject) in Chemistry—The Registrar, The University, Reading (May 25).

Assistant Lecturer or Lecturer (with special qualifications in stratigraphy and/or palæontology) in Geology—The Registrar, The University, Sheffield (May 26).

Henry Bell Wortley Chair of Metallurgy—The Registrar, The University, Liverpool (May 26).

Senior Lecturer or Lecturer in Biochemistry—The Registrar, The University, Sheffield (May 26).

Assistant Lecturer in Chemistry, and a Research Assistant in the Department of Chemistry—The Registrar, The University, Manchester 13 (May 28).

Assistant Lecturer (preferably with an interest in economic geography) in Geography—The Registrar, University College, Leicester (May 31)

Engineer (with an honours degree or equivalent in physics or electrical engineering, and experience in the design and construction of electronic apparatus) in Charge of Nuclear Equipment—Dr. F. B. Kipping, University Chemical Laboratory, Pembroke Street, Cambridge (May 31)

Lecturer in Experimental Physics of the Solid State, and Research Fellows and Students in Experimental Solid State Physics—Professor of Natural Philosophy, The University, Glasgow, W.2 (May 31).

Assistant Lecturers (2) (honours graduates in chemistry with research experience) in Chemistry—The Registrar, College of Technology, Manchester 1 (June 1).

Lecturer (with an honours degree in physics and postgraduate research experience) in Physics, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 1).

Lecturers (2) in Mechanical or Production Engineering—The Registrar, College of Technology, Manchester 1 (June 1).

Senior Lecturer in General and Social Psychology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (Australia, June 30).

Abstractor, Scientific Assistant grade (graduate, under 32 years of age, with a good reading knowledge of Russian, also preferably other Slav and unusual languages, and a knowledge of plant biology) —Commonwealth Forestry Bureau, South Parks Road, Oxford.

Assistant Lecturer (Grade B) in the Department of Applied Chemistry—The Secretary, Northampton Polytechnic, St John Street, London, E.C 1.

Assistant Lecturer (Grade B) in the Department of Electrical Engineering and Physics—Clerk to the Governing Body, Borough Polytechnic, Borough Road, London, S.E.1.

Assistant Lecturer, Grade B (with an honours degree in chemistry, and able to teach one branch of chemistry up to B.Sc special chemistry degree standard) in the School of Chemistry—The

Registrar, College of Technology and Commerce, The Newarke, Leicester.

ASSISTANT PROFESSOR OF BIOCHEMISTRY—The Chairman, Department of Biochemistry, Dalhousie University, Halifax, Nova Scotia, Canada.

ASSOCIATE PROFESSOR, and an ASSISTANT PROFESSOR IN THE DEPARTMENT OF PHYSICS—University of New Brunswick, Fredericton, N B., Canada.

COMPUTER (preferably woman graduate) IN THE MATHEMATICS DEPARTMENT—Assistant Secretary, University College, Gower Street, London, W.C.1.

GEOLOGISTS (preferably single, with an honours degree in geology, although those with lower qualifications may be considered; of high physical standard and a genuine interest in polar research and travel, and a real enthusiasm for hard work under trying conditions) with the Falkland Islands Dependencies Survey, for service in the Antarctic—The Crown Agents, 4 Millbank, London, S.W.1, quoting M3B/43195/TA.

HEAD OF THE MECHANICAL ENGINEERING DEPARTMENT—The Principal, Royal Technical College, Salford 5.

LECTURER (with a degree in electrical engineering or equivalent, and experience in radio engineering) at the R.E.M E. Training Centre, Arborfield—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. D.165/7A.

PHYSICIST (preferably with an honours degree in physics, and a good knowledge of and special interest in electronics) to work on problems associated with the maintenance and development of electronics equipment used in the various branches of medical research and investigation—The House Governor, Westminster Hospital, St John's Gardens, London, S.W.1.

SENIOR LECTURER IN INORGANIC AND PHYSICAL CHEMISTRY—Northern Polytechnic, Holloway, London, N.7.

SENIOR MATHEMATICAL MASTER—The Headmaster, King's College, Taunton.

SENIOR SCIENTIFIC OFFICERS (honours graduates or equivalent, and preferably with some industrial and technical experience); and SCIENTIFIC OFFICERS (graduates, preferably with an honours degree or equivalent), for work which will include research into problems connected with the coking industry, the preparation of technical reports, and may involve participation in operational research in the provinces from time to time—The Secretary, British Coke Research Association, 74 Grosvenor Street, London, W.1.

SPECIALIST (Plant Pathologist) (with at least a second-class honours degree in botany followed by one year's postgraduate training or approved experience in applied plant pathology or mycology, preferably including the study of virus diseases) IN THE DEPARTMENT OF AGRICULTURE, Gold Coast Local Civil Service, for duties which are concerned with the cultivation of cocoa and include planning and execution of plant pathological investigations, directing and advising phytosanitary measures, and administering staff, equipment and laboratory—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD 63/13/09.

STATISTICIAN (with a good honours degree in mathematics or statistics, and preferably an interest in agricultural research)—The Secretary, Grassland Research Institute, Hurley, Maidenhead, Berks.

WARDEN/LECTURER (with a degree or national diploma in agriculture and good practical experience, and preferably experience in teaching) IN CROP HUSBANDRY—The Principal, East Riding Institute of Agriculture, Bishop Burton, Beverley, E. Yorks.

DOCUMENTATION of MOLECULAR SPECTROSCOPY

THE DMS SYSTEM

The publication of a new system of documenting infra-red and Raman spectra on punched cards is announced jointly by Butterworths Scientific Publications, London, and Verlag Chemie, Weinheim/Bergstrasse, West Germany.
The new system combines a survey of current literature (i.e., an abstracting service) with an expanding collection of selected spectra of purified substances.

THE DMS SYSTEM provides two kinds of cards. The *Literature Cards* contain abstracts of papers relevant to molecular spectroscopy which appear in the literature. A *Spectra Card* is published for every substance of which a spectrum of satisfactory quality has been described. There are two identical editions, one in English, the other in German.

A leaflet giving full particulars of the system and the method of publication is now available, on request from the publishers.

LECTURES AND COURSES

UNIVERSITY OF EDINBURGH

Principal: Sir Edward Appleton, G B E., K.C B., D Sc , F R S

DIPLOMA IN ELECTRONICS AND RADIO

The one year postgraduate diploma course in electronics and radio will commence on October 9, 1956, and will provide specialized training for those wishing to proceed to research in this field or to employment in industrial organizations. Applicants should hold an honours degree in electrical engineering, mathematics or physics The main lecture courses are in network theory, principles of valve circuits, transmission and radiation theory, and particles in fields Laboratory and field work will be arranged to support the lecture courses A limited number of grants can be made available for suitable candidates

Further particulars and application forms can be obtained from the Assistant Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, 8

JOHN MacPHERSON,
Assistant Secretary to the University

UNIVERSITY OF LONDON

A course of three lectures on (i) " The Growth of Knowledge of Animals in Palestine from Palaeolithic Times " ; (ii) " The History of Science and the Neoplatonic Renaissance in Italy " ; (iii) " Knowledge and Biology " will be given by Professor F S Bodenheimer (Jerusalem) at 5:30 p m on May 14, 16 and 17 at University College (Anatomy Theatre), Gower Street, W.C.1

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar

UNIVERSITY OF BRISTOL

DIPLOMA IN HORTICULTURAL SCIENCE
DIPLOMA IN PLANT PATHOLOGY AND PROTECTION

The above postgraduate diploma courses will be available during the session 1956-57. Conducted in part at the Long Ashton Research Station, they are intended primarily for those with good honours degrees in science who seek careers in horticultural research, at home or overseas.

The horticultural science course commences on September 10, the plant pathology course on October 1. Both extend over a full session of three terms ending in June or July, and include some additional practical work during the vacations. Early application should be made to the undersigned, from whom full particulars may be obtained

H C. BUTTERFIELD,
Registrar

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952.

UNIVERSITY OF SHEFFIELD

Applications are invited for a post of Senior Lecturer or Lecturer in Biochemistry, to begin duties on September 1, 1956, or as soon as possible thereafter. Salary scales (a) for candidates holding a registered medical qualification, Senior Lecturer £1,750 by £100 to £2,050; Lecturer, £1,000 by £100 to £1,700. (b) For other candidates, Senior Lecturer, £1,400 by £50 to £1,650; Lecturer, £650 by £50 to £1,350. Commencing salary in either grade according to qualifications and experience, with F S S U. provision and family allowance.

Applications (eight copies), should be sent to the Registrar, from whom further particulars may be obtained, by May 26, 1956.

THERE WILL BE A VACANCY IN THE Department of Mathematics in the Joint Faculty of Arts and Science at Dalhousie and King's Universities this September. The position will be that of Lecturer (salary $3,000 to $4.000); or Assistant Professor ($4,000 to $5,000) depending on qualifications. There is a good possibility of the position being permanent after two years The work will probably involve teaching three undergraduate classes and one advanced class, three times each week, from late September to late April.—Further information can be obtained from and all applications should be made to: Dean of Arts and Science, Dalhousie University, Halifax, Nova Scotia.

ROYAL MILITARY COLLEGE OF SCIENCE

SHRIVENHAM, BERKSHIRE

The Civil Service Commissioners invite applications from men for the following posts under the War Department:

(a) One Principal Lecturer in Applied Chemistry.

(b) One Senior Lecturer in Radar and Telecommunications or Electronic Instrumentation.

(c) One Senior Lecturer in Engineering Physics.

(d) One Senior Lecturer or Lecturer—Mechanical Engineering: Applied Thermodynamics

(e) Two or more Senior Lecturers or Lecturers—Electronics.

(f) One Senior Lecturer or Lecturer—Chemistry.

(g) One Senior Lecturer or Lecturer—Physics.

(h) A number of posts, normally tenable for three years, as Demonstrators in Mechanical Engineering or Electronics or Electrical Engineering or Instrumentation.

Posts are unestablished but candidates appointed to posts (a) to (g) will be considered for established (i e., pensionable) posts as they occur and unestablished service will, subject to the normal rules, count for superannuation purposes under the Superannuation Acts (which also provide gratuity for unestablished service lasting for more than seven years). For posts at (h) provision is made under F S.S U Teaching work is at university level and candidates must have an appropriate degree (at least second-class honours) or equivalent. Research, for which there are excellent facilities, is encouraged.

Particular qualifications required as follows For post (a) (to be Head of the Applied Chemistry Branch) ability to organize lectures on fuels and combustion, chemistry of explosives, lubrication, non-metallic materials and ammunition. Previous experience of any of these, or of related fields of work, desirable. Research experience essential. For (b), experience in research, design or teaching in at least one of radar, telecommunications, missile guidance and electronic instrumentation For (c) experience in computing and/or servomechanisms and (if possible) in one or more of instrumentation, guided weapon control or fire direction. For (d), qualifications in applied thermodynamics. For (e), specialized knowledge of either electronics or telecommunications. For (f), some research experience and specialization in physical chemistry an advantage For (g), a knowledge of nuclear science is desirable and ability to teach essential.

Age: Principal Lecturer at least 31 on January 1, 1956; Senior Lecturer at least 26 on that date. Appointment to Senior Lecturer at lower age may be made exceptionally. Lecturers and Demonstrators at least 21 and under 28 on that date with extension for regular Forces service and for permanent service in the Experimental Officer class

Inclusive Salaries: Principal Lecturer, £1,185 to £1,567; Senior Lecturer, £1,030 to £1 185; Lecturer, £488 to £885; Demonstrator, £508 to £645 In assessing starting salaries of Lecturers credit will be given for approved postgraduate experience and National Service but will not exceed, for example £660 at age 25 or £832 at age 30. For other posts consideration will be given to special circumstances Secondment from, and transfer to, Scientific Civil Service may be arranged The College is residential, houses available at economic rents for married men and quarters in residential officers' mess at reasonable charges for single men. Successful candidates to take up duty in October, 1956, or as soon as possible.

Further particulars and application forms from Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W 1, quoting No. S 4584/56/8 Application forms must be returned by May 12, 1956

THE MEDICAL COLLEGE OF ST. BARTHOLOMEW'S Hospital, West Smithfield, E C.1. Applications are invited from medically qualified graduates for the post of Junior Lecturer in Pharmacology, tenable as from July 1, 1956, or as soon as possible thereafter. The salary is on a scale of £700 by £50 to £900 per annum, together with family allowance and membership of the F S S U The successful candidate will undertake teaching of medical students and will be expected to participate in a research project in Clinical pharmacology —Applications, which should be received not later than May 31, 1956, should be addressed to the Dean of the Medical College, from whom further particulars may be obtained.

LABORATORY ASSISTANT WANTED FOR School Physics Laboratory. Salary according to qualifications up to £640 per annum. Some experience essential —Write, giving full particulars, to Mr. P. Bateman, Highgate School, London, N.6.

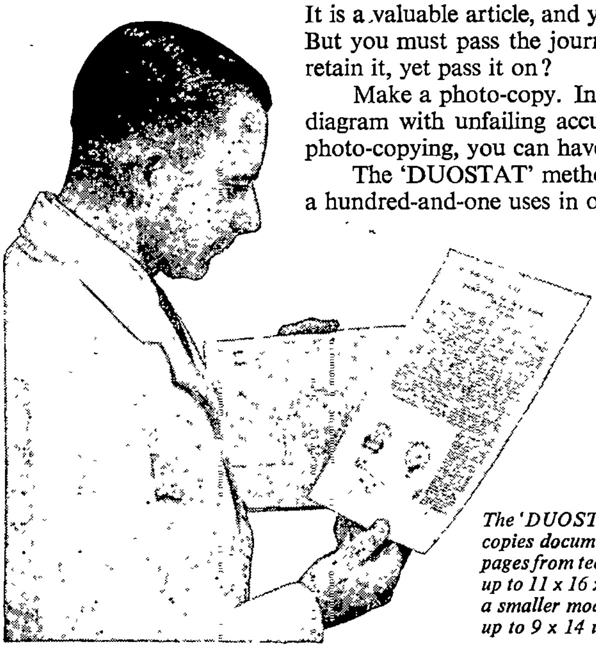
An article from 'NATURE'

It is a valuable article, and you wish to retain it for personal study and reference. But you must pass the journal on to others in your organisation. How can you retain it, yet pass it on?

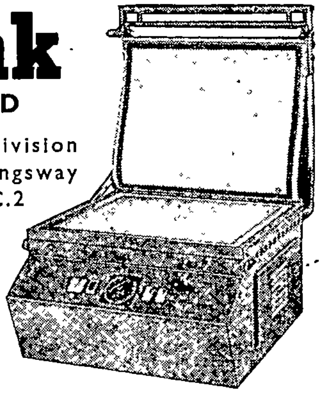
Make a photo-copy. In this way you can reproduce every word, symbol and diagram with unfailing accuracy. And, if you use the 'DUOSTAT' method of photo-copying, you can have your copy in less than three minutes.

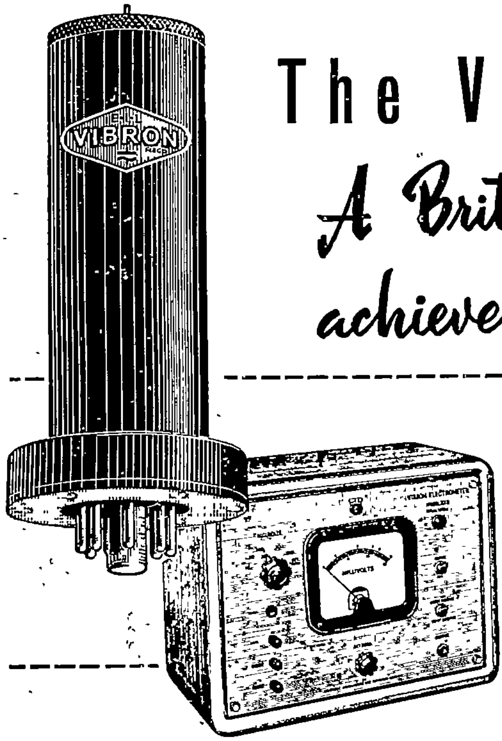
The 'DUOSTAT' method is convenient, clean and inexpensive. And it has a hundred-and-one uses in offices and laboratories. Let us send you details.



Kodak
LIMITED
Industrial Sales Division
Kodak House, Kingsway
London, W.C.2

The 'DUOSTAT' Printer Model 14/18 copies documents up to 14 x 18 inches, pages from technical journals and books up to 11 x 16 x 1¼ inches. There is also a smaller model for copying documents up to 9 x 14 inches.





The VIBRON

A British achievement!

The Vibron Electrometer is a new instrument for measuring, with exceptional stability, very small currents from a high impedance source.

The 'heart' of the instrument is the E.I.L. VIBRON vibrating condenser unit, a precise electro-mechanical device which performs some 50 times better than the conventional electrometer valve.

The Vibron Electrometer is being used for ionisation current measurements, as an ultra stable pH meter and as a very high resistance megohmmeter.

Manufactured under British Patent No 550610 and Patent Application No. 35637/54

Developed and marketed exclusively by:

NUCLEAR POWER AND ITS DEVELOPMENT IN BRITAIN

THE reference in the recently issued annual report of the Department of Scientific and Industrial Research to the European Organization for Nuclear Research is comparatively brief; but it is clear that the scale of the British contribution in this field is growing. The Advisory Council notes in this report that impressive progress has been made since the inter-government convention came into force in October 1954, that the staff of the Organization is now between two and three hundred and that some research is already in progress. In the year covered by this report, Great Britain's contribution was almost £360,000; £520,000 was provided in the Estimates for 1955–56; while those for 1956–57 provide £930,000, or more than 10 per cent of the Department's gross budget of nearly eight and a half million pounds. Besides this, there are the Department's grants to universities for nuclear physics research, which are running at the rate of a quarter of a million a year, and there is the proportion of the vote for atomic energy which is spent on research and development. For 1955–56 and 1956–57 the vote itself is a little more than £54 million and £68 million, respectively; but the Civil Estimates give no information as to expenditure on research and development. It can only be assumed that approximately £2 million in 1955–56 and £2·5 million in 1956–57 which is being expended on work by industry and at universities is for such purposes.

It is clear, therefore, that neither the annual report of the Department of Scientific and Industrial Research nor the Civil Estimates gives the scientific and technical world sufficient information for a sound judgment as to whether or not the scientific and technical effort in Britain in the nuclear energy field, either in research or in development, is in balance with other activities and resources of the country. When all allowance is made for the extent to which security considerations make it imprudent to disclose the nature and magnitude of that effort where it relates to defence, maintenance of secrecy is detrimental to the efficient use of resources in the development of nuclear energy for peaceful purposes and to effective co-operation with industry. Nor is it reasonable to withhold information which would enable better judgment to be formed as to the scale of the British contribution to European co-operation in that field, when that contribution exceeds 10 per cent of the total budget of the main institution in Britain for the administration of Government support for research.

Concern in this respect might be less were it apparent that the Office of the Lord President of the Council was being appropriately strengthened to discharge its growing responsibilities for the general supervision of the nation's scientific effort. The Civil Estimates for 1956–57 disclose no such signs. The staff of nine remains unchanged, and the estimate of £14,345 compares with £13,370 in 1955–56 and with a staff of eighteen and vote of £19,400 for the presumably subordinate Atomic Energy Office, and a staff of twenty-three and vote of £28,620 for the University Grants Committee. The unsatisfactory situation which leaves the House of Commons with no minister or parliamentary under-secretary directly responsible for the nation's vast interests in science and technology persists, and the Bill to change the administration of the Department of Scientific and Industrial Research does not touch this formidable problem, which has recently been the subject of 'questions' in the House.

Quite apart from this question of the balance and effective co-ordination of the research effort of Britain, it is not surprising, therefore, that the Government should have been pressed for more information as to its attitude to European co-operation in the development of nuclear energy for peaceful purposes and to the industrial development of nuclear energy in Britain itself. On the first point, the Lord Privy Seal, Mr. R. A. Butler, on February 29, declined to say anything about the discussions then proceeding at the ministerial meeting of the Council of the Organization for European Economic Co-operation in Paris, nor did a bulletin issued that week by the Information Division of the Treasury add to Mr. Selwyn Lloyd's statement of February 15. Although no ministerial pronouncement has yet been made, it would seem that at that meeting the Foreign Ministers of the six countries constituting Euratom avoided discussions in February. The Organization for European Economic Co-operation, however, comprises eleven countries, including Britain as well as these six, and there appears to be no reason why it should wait on the six before determining its part in the development of nuclear energy.

The meeting of Ministers in Paris in the first week in March appointed a special committee which is to formulate detailed proposals during the next three months on five specific questions. Two of these relate to procedure. The committee is to make recommendations on the functions of a steering committee for nuclear energy which is envisaged as the permanent organ of the Organization for European Economic Co-operation for co-ordinating and directing European co-operation in this field, and also on the means of co-ordinating the action of existing organizations, such as Euratom. This committee is also to report on the nature of security controls required to prevent the diversion of fissile material, on the joint undertakings to be sponsored by the Organization for European Economic Co-operation, and on the steps to be taken to keep intra-European trade in nuclear equipment and materials as free from restrictions as possible. The committee was specifically authorized to consult the United States Government about the implications of the American offer to sell or lease 20,000 kgm. of uranium-235 for use in research and power reactors in countries outside the United States not at present producing it themselves.

These are sensible decisions; but what needs to be emphasized is that bold decisions are required and that they cannot be postponed if Western Europe is to reap the advantages which nuclear energy can offer. Such questions as whether nuclear energy is to be developed for peaceful purposes only, whether the proposed Commission shall have supranational powers or not, and whether it shall be the sole owner of fissile material cannot be evaded indefinitely. The answers to be given determine alike the form of the organization itself and the extent of the support which it receives from different countries. Moreover, they may react on the form which developments take in particular countries, and for that reason alone the growth of Euratom may prove to be closely related to the way in which the development of nuclear energy proceeds in Britain. One such point is in regard to the control of private industrial development, on which Mr. Butler was also questioned on February 29. Mr. Butler replied that since at present the essential nuclear fuel can be obtained only from the Atomic Energy Authority, the administrative control through the Authority is adequate for the Lord President of the Council to carry out his duties under the Atomic Energy Act; however, the Lord President is considering to what extent the growing interest of private industry in this field would call for the exercise of powers available under the Atomic Energy and Radioactive Substances Acts, 1946–54, to supplement or replace existing arrangements. Pressed further, Mr. Butler said that he is satisfied that the powers under these Acts are adequate.

A further statement on the relation between the State and private industry in the development of nuclear energy was made by Mr. Butler on March 14. In reply to specific questions from Mr. W. N. Warbey, he said that the current civil allocation of plutonium and uranium-235 is sufficient for the present programme of more advanced types of civil power and research reactors, and that in spite of the main limiting factor of the shortage of suitably qualified scientists and engineers both in the Atomic Energy Authority and in industry, no radical departure from the nuclear power programme outlined in the White Paper of February 1955 is contemplated. Mr. Butler said that the Government considers that the relation between the State and industry in this field should be one of close partnership subject to the maintenance of a proper degree of control by the Government; much of the necessary research, development and production will have to be carried on by the Atomic Energy Authority, if only because of the high cost of the capital facilities required. Some activities, such as the import and processing of uranium and the separation of uranium-235 in the diffusion plant, must remain responsibilities of the Authority alone, because they concern defence as well as civil requirements, and the nuclear fuel required by industry would be provided on loan. On the staff question, he said afterwards that 3,465 out of 4,202 established non-industrial Civil servants have accepted offers of employment and signed contracts with the Authority, and that the Authority's total staff is at present about 22,000.

For the rest, the Government hopes that both private and nationalized industry will enter as rapidly and extensively as possible on the commercial application of nuclear energy. The nuclear power stations to be built in Britain for the production of electricity will be designed and constructed by private industry —and private industry, not the Authority, will fulfil export orders. The Authority will give industry the maximum of help which its technical resources permit, subject to safeguarding two points: first, the Authority should, where appropriate, be paid for commercially valuable information (including the use of patents owned by the Authority) which has been acquired at considerable expense; and, second, that firms are not enabled to use the assistance afforded by the Authority to build up exclusive rights for themselves.

The access agreements made by the Authority with private firms contain provisions to cover these points. Such agreements naturally vary according to the nature of the transaction, and Mr. Butler pointed out that it would not be consonant either with sound commercial practice or with the Authority's freedom to manage its day-to-day business on commercial lines that it should be required to publish such details, or that the Lord President should be answerable for them. In an earlier answer on February 22, Mr. Butler had indicated that the terms for the loan of nuclear fuel will cover the cost of fabricating the fuel elements, a percentage of the total cost of the fuel, including a part for research and development, the cost of fuels spent in running the reactor, and the cost of re-processing spent fuel elements. On March 21, Mr. Butler declined to give further details about particular agreements, but said that payment for the use of patented inventions would depend on the extent to which patents owned by the Authority were in fact used, and that the Lord President does not at present intend to make an order providing that the acquisition, production or use by private industry of nuclear fuels or plant for the production or use of nuclear energy will be permitted only under official licence. It may, however, be necessary later to re-examine the extent to which the Government should use the powers available in regard to safe construction and operation under the 1948 Act.

Mr. Butler also answered a number of questions regarding the export of nuclear energy plant and equipment. Discussions proceeding for some time between the Atomic Energy Authority and representatives of the heavy electrical plant manufacturer on the possibilities of export trade in nuclea power reactors are being widened, and considerable publicity is being given to the United Kingdom's achievements and potentialities. The United Kingdom has already established a substantial export trade in isotopes and new types of instruments for use in industry and research; but the commercial development of nuclear power is still in its infancy, and a substantial demand for, or expor of, power reactors is unlikely for some years. Long-term plans in this field are already being considered by the Lord President and the Atomic Energy Authority with the President of the Board of Trade. Mr. Butler agreed that the proposals made by the working party of the Organization for European Economic Co-operation for the nuclear energy industry would offer an admirable outlet for the industry of Britain but declined to enlarge on the subject.

It may be recalled that on February 28, in welcoming President Eisenhower's imaginative offer to supply uranium for the development of the peaceful uses of nuclear energy, the Prime Minister referred to developments under the Colombo Plan and Bagdad Pact, as well as in bilateral arrangements between the United States and Great Britain and certain countries in Africa and Asia to help them in training in the peaceful uses of nuclear energy. On March 21, Mr. Butler again emphasized the disability of Britain, compared with the United States, in regard to supplies of enriched uranium; but he undertook to consider further the allocation of such supplies between defence and civil needs and the possibility of obtaining supplies from the United States. Again, in the debate on the international situation in the House of Lords on March 27, Lord Layton pleaded for strong support by Great Britain of the proposals made by the Organization for European Economic Co-operation for the co-operative control of the development of nuclear energy, urging that it is all-important that we should be associated at the start with the development for peaceful purposes of nuclear energy.

Lord Reading, in replying for the Government, claimed that the Government is at present considering how far the Euratom proposals and those of the Organization for European Economic Co-operation can usefully be dovetailed one into the other, and that it is not at all indifferent towards the idea of assisting the various European organizations which exist. Nevertheless, it may be doubted whether, even from the point of view of Britain's own interests, the Government has been sufficiently imaginative as regards the proposals for European co-operation in this field. A central organization strong enough to control the uses of nuclear fuel, to promote the joint construction of nuclear power plants and to negotiate with the United States on the offer of uranium would have advantages also in the administration of technical aid from Europe to the undeveloped countries of Asia and Africa. Particularly in the Middle East, it might offer some prospect of abating the political tension which too often has attended the giving, or even the offer, of assistance by individual countries.

But the questions and statements in Parliament regarding the development of nuclear energy for industrial purposes have scarcely so far touched on the vital issues. The important question, now that a beginning has been made with such applications in industry, is not so much whether the conditions of co-operation between the Atomic Energy Authority and private industry ensure the Government the necessary control, or even that industry pays a reasonable price for the information and technique placed at its disposal. There is little reason to fear that the national interest will suffer in either of those respects. What is much less certain is that the conditions of co-operation are such as to encourage the initiative and enterprise and the taking of risks that are inseparable from new ventures.

While British firms are at last being allowed to participate in the design of nuclear power stations, in research into nuclear power plants for aircraft engines, in the development of an atomic submarine for the Royal Navy, and in the development of nuclear power for shipping, and one is being supplied with fuel for the research reactor which it is to build for itself, it must be remembered that there are only a few enterprises in Britain that have the technical and financial resources to take up nuclear engineering. There has indeed been a further relaxation of the old secrecy about the technical processes in Britain's nuclear factories, and the British Government is prepared to supply natural uranium for any power station which a British firm may sell abroad.

None the less, it will take all the technical skill and enterprise which Britain's scientists and engineers can produce to offset the advantage which the United States possesses in being able to offer much more abundant supplies of the enriched uranium for the same purpose; so long as restrictions inevitably imposed by bilateral agreements between users of uranium and the British or American Governments remain, the nuclear energy authorities will be the final arbiters of the speed of progress, and doubts will persist as to whether the possibilities are being explored with all the imagination and enterprise that are available. One advantage of associating private industry with a public authority is that the former can take risks that no public body can afford to do with public money.

But industry cannot be kept indefinitely in leading strings and subject to monopoly rights over the whole field of nuclear energy which the Atomic Energy Authority has hitherto possessed. Even now it is doubtful whether the nuclear physicists and engineers in Britain as a whole possess the experience to judge whether the programme set forth a year ago in the White Paper is still sound, or whether a further experimental programme even on the design of nuclear power plant is desirable. Until, however, such questions can be discussed realistically and responsibly in the scientific and technical Press, it is impossible to judge whether the efforts of the thousand scientists and technologists which Sir John Cockcroft estimates are working on nuclear power development in Britain are wisely directed, and how sound in relation to available resources is the annual expenditure of £200 million on nuclear power stations contemplated from 1965 onwards.

It would not be reasonable to suggest that the Atomic Energy Authority is averse to experiment outside its own establishments; but it is understandable that it may be somewhat prejudiced in its judgment. Nor, even with the strongest motives for encouraging development in industry, rather than in its own establishments, can it be assumed that the Authority is necessarily the best judge of the worth of an experiment. It is altogether in the nation's interest that industry should be encouraged to engage in longer-range experiments, while the Authority is preoccupied with the immediate development of nuclear power stations; and if some relaxation of the Authority's right to acquire the patent of any invention which it judged relevant to the development of nuclear energy would stimulate such enterprise, the relaxation would be well worth while. What matters above all in such a field is imagination and enterprise, and methods of control or forms of organization which repress initiative and discourage experiment and the taking of risks, either by the industrial firms or at the international level, so far from ensuring security endanger the whole economic future of Britain.

It should not, therefore, be taken for granted that the Authority's present ideas of its partnership with industry should govern that partnership indefinitely. Industry may be content to rent fuel from the Authority in the first instance; but if industry's first designs work, it may reasonably expect permission to fabricate the actual elements itself from billets of uranium supplied on a rental basis. Nor would it be unreasonable for industry to hope in due course to take a larger part in applied nuclear research, and to be admitted to real partnership with the Authority on common research projects. Such developments could not fail to be in the national interest; and although they are not immediate issues, it is not too early to be giving thought to such differences of interpretation of the "close partnership" and their reconciliation, as well as to the relative scale of the total effort which Britain can afford to make in the development of nuclear energy. The secrecy problems now arising in development work out of the association of the Authority with different industrial interests should be handled from the start with sufficient forethought to avoid prejudicing future relations of the Authority with industry in general. The draft statute for an international atomic agency, approved in April in Washington by a group of nations, should stir the British Government and the Atomic Energy Authority to think ahead and approach problems of secrecy, security control and industrial partnership with vision and energy.

BIOLOGY OF PUBERTY

Growth at Adolescence

By Dr. J. M. Tanner. Pp. xii+212. (Oxford: Blackwell Scientific Publications, 1955.)] 32*s.* 6*d.*

HUMAN growth and maturation have been explored during recent years with immense enthusiasm, particularly in the United States. On the descriptive plane much information has been accumulated from anthropometric, photographic and radiological observation. Some physiological and endocrinological facts have also been gleaned, and much has been written on the psychology of adolescence. What biological insight has been obtained into the processes which overtake the human body at puberty? In this succinct monograph Dr. J. M. Tanner provides an appraisal which displays the real achievements as well as the considerable deficiencies in our present knowledge. The achievements rest mainly on the more exact description of the 'external' events of pubescence, the changes in dimensions of the body and its segments, the relative growth of different tissues, the individual variability of response and the developmental contrast of male and female. The deficiencies affect particularly our understanding of how the sequence, synchrony and changing tempo of events are regulated, and what is happening to the brain and endocrine system.

The merit of Dr. Tanner's presentation is that he conducts the reader with directness to the essentials. At the outset he insists on the use of 'velocity' rather than the usual 'distance' curves of growth to display the sharpness and timing of the adolescent 'spurt'; and he explains also that many of the shortcomings of the data arise from failure to follow the same children consecutively. The adolescent spurt is shown to be a general event affecting the facial, cranial and body skeleton, in a particular sequence, as well as viscera, musculature and other tissues. Coupling these morphological changes with events in the reproductive system leads him to a consideration of the concept of bodily maturity and of its assessment. The main conclusions here are the existence of a "tendency for a child to be advanced or retarded as a whole; in the percentage attained of his eventual size, in his skeletal ossification, in his permanent dentition, doubtless in his physiological reactions, and also in his intelligence test score" (p. 62), and the inadequacy of chronological age to reflect the physiological status of the individual.

Of the factors determining or modifying growth at adolescence, very little can at present be said of the genetic basis or of the influence of race or climate; rather more is known of nutritional effects, where it seems likely that "the time of occurrence of the adolescent spurt is a more sensitive indicator o nutritional deficiency than is the growth rate at earlier periods" (p. 85); there are definite socio-economic differences in growth for which various explanations are considered (though the significance of differential fertility is not); information on the effect of illness appears to be very limited (but Harris's bone lines are not mentioned). Substantia evidence is adduced for the belief that the onset o adolescence has been speeding up in many countries during the past fifty years or more. Whether the adult body size has also increased with this accelerated maturity is said to be a matter of dispute (p. 86) although no data are given opposing the affirmation (p. 92) that the "ultimately reached adult size is greater".

The possibilities of predicting size and physique o attainment of maturity from chronological or developmental age have naturally engaged much attention Such predictions are complicated by the influence which the time of onset of the adolescent spurt exerts on the developing physique. Nevertheless, the extent to which the pre-adolescent physique can be remoulded by this factor is stated to be relatively small, and no 'radical' change in body build ensues. This conclusion is important enough to deserve a more detailed demonstration, as is the claim "that there is little doubt that someone used to looking at children's photographs could predict with accuracy the adult somatotype from a picture taken at age 5 or even earlier" (p. 78).

Of the complex and interrelated endocrinological happenings at adolescence Dr. Tanner shows how limited and careful interpretation must remain at present. When it comes to tracing the changes in mental ability at puberty and their relation to neural events, the information peters out.

This book will certainly be of service to a wide circle of students of human biology and medicine. It provides also the basis for an attractive and highly instructive pre-clinical course for medical students.

J. S. Weiner

CHEMICAL TECHNOLOGY

Encyclopedia of Chemical Technology

Edited by Raymond E. Kirk and Donald F. Othmer. Vol. 11: Polyols to Rutin; pp. xvi+950. Vol. 12: Sabadine to Stilbestrol; pp. xvi+955. Vol. 13: Stilbite to Thermochemistry; pp. xvi+952. Vol. 14: Thermodynamics to Waterproofing; pp. xvi+980. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1953–55.) 30 dollars each volume.

THESE further four volumes of Kirk and Othmer's "Encyclopedia of Chemical Technology" deal with subjects from polypropylene to water. Vols. 1–10 have already been reviewed in these columns (*Nature*, 164, 935 (1949), and 173, 228 (1954)). The "Encyclopedia" is designed to provide, from an industrial point of view, a summary of knowledge of materials, methods, processes and equipment for the chemist and the chemical engineer. It contains authoritative articles, arranged alphabetically, by experts from the chemical industry and research institutions in the United States. Thus it is an American production. It provides a vigorous, clear, informative and up-to-date picture of chemical technology as practised in the United States. It will be valuable, and even indispensable, in chemical laboratories and industrial libraries; it would indeed be useful to individual men of affairs to provide them with information about other subjects not immediately in their purview. It is useful also to the teacher of chemistry and chemical engineering and to the student, for the articles relating to the scientific basis of technology seem to be presented in a way which includes the essentials without overloading them with unnecessary details. Furthermore, the lay-out of the articles, the arrangement and the printing are very satisfactory and the diagrams are well chosen and highly informative.

The subjects dealt with in these four volumes include articles on the main branches of chemical industry, among which may be cited, for example, printing, pulp, pyrotechnics, rayon, refrigeration, rubber, salt, silicones, soap, solvents, steel, sugar, sulphuric acid, tanning, tea, textile technology, tobacco, varnishes, industrial wastes and water. There are also valuable articles on techniques: for example, powder metallurgy, pressure measurement, technique for high pressures, radiography, sampling, size measurements of particles, staining, temperature measurement, ultrasonics, vacuum technique, and viscometry (volume measurement is cross-referenced to fluid mechanics in an earlier volume). Another class of article is that relating to particular processes, such as power generation, quality control, safety precautions, sedimentation, silvering, size separation, spraying, etc.

Then there are articles dealing with the properties, production, and use of individual chemical substances or classes of substances. Many of these articles, like those relating to silica and inorganic silicates, are highly informative. It is useful to have recent information such as is provided by the articles on titanium, tantalum, the terpenes, the vat dyes, etc. There are a number of articles relating to pharmaceutical products, and substances of therapeutic value such as streptomyces antibiotics, stimulants and depressants, sulphur drugs, thyroids and antithyroid preparations, vaccines, vitamins, etc.

Besides all this, there are a number of satisfactory articles on the physical-chemical basis of chemical technology: radicals, radiochemistry, Raman effect, reaction kinetics, stereochemistry (organic and inorganic), thermochemistry, thermodynamics, valence, vapour-liquid equilibria, etc.

Separated in this way, some indication is given of the contents of these present volumes under review. There are other articles which lie outside such a classification: for example, those on trade marks and smokes and fumes. The latter article includes a table of the threshold or maximum concentrations, for continuous eight-hour exposure with no impairment of health, of various gases and vapours present in industrial atmospheres, together with the dangerous and fatal concentrations. It also provides tables of collector equipment for solid and liquid aerosols, their efficiency and the estimate of costs. Much attention has been paid to atmospheric pollution by industry in the United States during recent years, and such an article summarizing some of the results of inquiry is particularly useful.

There are other articles which also lie rather outside the strictly scientific field; those, for example, on materials such as salad dressings, shampoos, tints, hair dyes and bleaches. These take up about fifty pages of these four volumes of 950 pages each; whether that is in proportion to the magnitude of these frills of civilization to that of the total chemical industrial trade of the United States has not been ascertained.

One can open the books at random and almost at any place find points of interest—a very good test of such books. For example, opening at p. 929 of Vol. 13, the reader finds a note on thallium oxide: "which begins to sublime at 300° C. in high vacuum although its boiling point is at least 1,080° C. . . . at higher temperatures some peroxide is formed". These are interesting facts, which accord with the reviewer's experience. Higher up the page, "the addition of 0·5 to 5 per cent Thallium to gold or silver for electrical contacts is claimed to reduce the tendency of these to stick"; that might be a useful tip.

The thirty-four page article on thermodynamics is particularly clear. It uses the nomenclature recommended by the American Institute of Chemical Engineers, which differs from the international one only in that A is used instead of F for the total work function.

Most of the articles are informative and satisfying: the expert in any particular field or the person who needs to follow up a subject could no doubt pick some holes, or be disappointed that there is not more detail. The merit of an encyclopædia, however, depends very much on striking the right balance between scrappiness and prolixity, and these volumes seem generally to contain well-balanced articles.

The survey article on the sugars perhaps omits too much, and that on the proteins seems to include very little of the results of interesting recent attacks on their structure by X-ray methods.

Some articles in some of their aspects and in relation to the quotation of bibliographical references are apt perhaps rather to overstress recent work in the United States and to understate the scientific development of the subjects as resulting from a world-wide effort. This is a tendency in every country, particularly in regard to technological subjects rather than to fundamental scientific subjects, and it should be avoided so far as possible.

This fifteen-volume work as a whole (there is one volume yet to come) is beautifully produced. Although it is costly, it is a worthy publication of a great industrial nation, and most technical libraries will need to keep it readily available.

A. C. Egerton

SKYHOOKS AND SATELLITES

200 Miles Up

The Conquest of the Upper Air. By J. Gordon Vaeth. Second edition. Pp. xiii+261. (New York: The Ronald Press Company, 1955.) 5 dollars.

The approaching International Geophysical Year of 1957–58, with the incidental project of an artificial satellite, has stimulated the second edition of this book, which first appeared in 1951. As head of the New Weapons and Systems Division in the United States Office of Naval Research, Mr. Vaeth speaks authoritatively, and it is good to read an account of upper-air research which, intended primarily for the general reader, is so completely scientific in its outlook. People naturally want to know also how far at the present time the fantastically improbable has developed towards the fantastically possible, and there is a little speculative spacemanship at the end. But this is not confused with actual achievements or projects seriously in hand, and the great value of the book is in its emphasis on the real objects of high-altitude exploration.

The reader will probably turn first to Chapter 12, which outlines the possible construction, and the problems of launching, instrumenting, and tracking the Minimum Orbital Unmanned Satellite of the Earth (entitled MOUSE) suggested by Dr. S. F. Singer. Circulating at a height of about two hundred miles, in a track passing over two stations near the poles, this would release stored information to the stations every half-revolution. (One can forecast that the whimsical trend of scientific jargon will find an appropriate name for the reception of these observations, such as 'taking the Mickey'.) Trial runs may first be made with uninstrumented projectiles. Launching will most likely be from ships at sea—not, as in the almost prophetic diagram in the "Principia", from a mountain-top. The life of such a satellite is expected to be a day or two.

The earlier chapters give an excellent account of the physics of the atmosphere, the information sought, the various instruments used, and the telemetering equipment for transmitting results from rockets and balloons. Pictures of the complete laboratories and radio stations fitted in modern rockets give a good idea of the complicated tasks each fulfils in its short mission. The activities at the White Sands Proving Ground are described at first hand, and the development from the early captured *V*2 to the W.A.C. Corporal is explained with a good deal of technical detail. The progress of the modern balloon, culminating in the gigantic Skyhook cells, which may be as large as three million cubic feet, is fully dealt with. To the rocket-minded, this revival of interest in large balloons may seem like an echo of the 1930 period. But the firing of a rocket is an event, and the recovery of the remains an enterprise, while unmanned balloons carry the routine traffic of the upper air, and are very much less costly. Indeed, Mr. Vaeth says that it is probable that the first steps towards a closer acquaintance with Mars will be made in the summer of 1956 from a manned balloon observatory, carrying a 6-in. telescope and spectrographic equipment above the disturbances of the earth's atmosphere. Little information is available about this, except that the craft will be called Explorer III, as a successor to the balloons manned under the late A. W. Stevens. Incidentally, Skyhook balloons, travelling rapidly in high-altitude winds, have been shown to account for many 'flying saucer' observations; indeed, as the photographs of them show, they look like nothing else. But the author records one unidentifiable object that was definitely not a balloon, and refuses to be drawn into controversy.

Admirable photographs, a readable style, and an objective approach make this a book which will be received both with enjoyment and with confidence.

G. R. Noakes

DIELECTRIC CONSTANT AND LOSS

Dielectric Behaviour and Structure

Dielectric Constant and Loss, Dipole Moment and Molecular Structure. By Prof. Charles Phelps Smyth. (International Chemical Series.) Pp. x+441. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 64*s*. 6*d*.

During the past ten or fifteen years, measurements of the dispersion of dielectric constant have been characterized by a new and altogether higher level of precision. This has been achieved partly by the development of microwave methods and partly by experimentation at low temperature when the dispersion is shifted into the radio- and audio-frequency region. The use of microwaves has the unique advantage that the investigation of electrolyte solutions has become practicable. Prof. C. P. Smyth's book is a timely summary of the knowledge and attitudes that are the result of these advances. The subject is treated in two parts. The first, a discussion of the dielectrical properties of matter, occupies rather more than half the book; the second part is devoted to a survey of dipole moments as a tool in the study of molecular structure. Comparison with the author's previous book published twenty-five years ago shows how great has been the expansion of the subject in the intervening time.

In fundamental theory the developments represent a consolidation rather than an advance to new positions, and it is perhaps of interest to glance at the current picture of the mechanism of dipole reorientation. Hindered rotation, introduced as a macroscopic concept twenty years ago by Debye and Fowler, emerges with a new look. The Lorentz field employed by Debye has tacitly been dropped in favour of the Onsager field, and the Onsager equation is accepted as a reasonable approximation for non-associated polar liquids. Analysis of dipole reorientation as a kinetic process has led to the evaluation of thermodynamic parameters which have illuminated the molecular interpretation of dielectric relaxation. It is agreed that a molecule usually rotates as a unit, the rotation of a prolate molecule about its long axis being demonstrably the easiest, although there are isolated examples of very large molecules wherein reorientation occurs by intramolecular torsion. The hindering effect of adjacent dipoles is emphasized by the observation that the energy barrier opposing reorientation is greater for a pure polar liquid than for a solution in a non-polar medium of the same viscosity. Associated liquids remain a difficult problem in spite of the early success of the Kirkwood equation relating the dielectric constant of water to its dipole moment. In this treatment the reorienting unit is a single molecule, an assumption powerfully supported by the fact that the dielectric loss in the principal dispersion region—rather surprisingly for a quasi-crystalline liquid—is compatible with a single relaxation time. Earlier theories which explained the high dielectric constant of associated liquids by the rotation of molecular aggregates (the simplest expression of co-operative effects) are therefore suspect, at least in their simplest form. In solids, transitions signalize the onset of molecular rotation which often is relatively free in crystals of high symmetry. The mechanism of dipole reorientation in ice is still unsettled, but there is now definite physical evidence in favour of a process involving non-classical proton transfer in certain solid alcohols.

Prof. Smyth writes for the chemist rather than the physicist or electrical engineer. In deriving the basic equations—not always rigorously—he is at pains to describe the physical background, a point which will commend itself to non-mathematical readers. A careful balance is maintained in areas of controversy, and his book is recommended to the honours student, general reader and specialist alike.

MICROSCOPY OF VEGETABLE FOODSTUFFS

Mikroskopische Untersuchung pflanzlicher Nahrungs- und Genussmittel

Von Dr. Gustav Gassner. Herausgegeben von Dr. Friedrich Bothe. Dritte, verbesserte Auflage. Pp. xvi+400. (Stuttgart: Gustav Fischer Verlag, 1955.) 33 D. marks.

ALTHOUGH the late Prof. Gustav Gassner's book on the microscopy of foodstuffs of vegetable origin, which was first published in 1931, has now reached its third edition, the reviewer has only recently had an opportunity of studying it for the first time. The author having died while the preparation of the third edition was still in progress, the work has been completed by Dr. F. Bothe. It must at once be emphasized that this book deserves to be much more widely known and used in Great Britain than it appears to be at present, and it is a work of reference that merits a place on the shelves of all public analysts, economic botanists and microscopists who are concerned with maintaining the standard of purity of foodstuffs, and detecting adulterants in them.

As its title implies the subject-matter of the book is essentially the microscopical structure of the products described in it, and it includes but little information concerning their sources and uses, although these are briefly mentioned.

The book is divided into thirteen chapters, twelve of which deal with such topics as cereals, starches, vegetables, condiments, beverages, spices, and seeds and fruits that are valued because of their content of oil. To give a few specific examples, the reader will here find particulars of the microscopical structure of a wide range of peas and beans, of arrowroot and sago, of dill and vanilla, of such diverse fruits as apples and dates, of cocoa and coffee, not to mention such homely vegetables as spinach and parsnips. There is a special chapter devoted to the microscopy of honey, and another on fungi includes details of morels and truffles and even of the *Penicillium* that is used for flavouring Roquefort cheese. The remaining chapter includes simple, effective, practical directions for examining foodstuffs under the microscope. The book ends with a good subject-index; but there is no bibliography.

The 866 line drawings by which the book is illustrated constitute one of its most useful features, and what a pleasure it is to find that all of them are original, well drawn, and show very clearly those characters that have proved to be the most valuable for diagnostic purposes. The illustrations are at a few selected magnifications, which have been used as standards throughout the book, so that the reader can at once form a mental picture of the relative sizes of the tissues and cells, as well as of the bodies enclosed in them, such as starch grains or crystals.

Although much of the information in the book is already available from other sources, it is an advantage to have clear and simple descriptions of the salient diagnostic characters of such a wide range of materials brought together within the compass of a book of no more than four hundred pages. The microscopical descriptions are so easy to understand that they could have been written only by a botanist with an intimate first-hand knowledge of his subject. Indeed, the whole book is manifestly based on the practical experience of the author and his colleagues.

Since the subject-matter is arranged according to the uses of the various items, rather than on a botanical basis, it follows that products derived from closely related botanical species are not always described in the same part of the book. Thus, for example, seeds derived from species of *Brassica* are described partly under oil seeds and partly under spices. This, however, is no serious disadvantage provided the reader realizes the position.

The reviewer is interested to note that many of the substitutes and adulterants described in this book are precisely the same as those which he has encountered in the course of his own work. It is indeed fortunate for microscopists whose business it is to ensure that a high standard of purity is maintained in economic plant products, that those bent on adulteration and substitution are so conservative in the selection of the materials they employ for these purposes.

C. R. Metcalfe

Gas Kinetics

An Introduction to the Kinetics of Homogeneous Gas Reactions. By A. F. Trotman-Dickenson. Pp. x+322. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1955.) 40*s.*

A NEW account of chemical kinetics by an active worker in the field is generally welcome, and the present volume is no exception to this. In his preface the author states that the book is written chiefly for undergraduates and for those beginning research. Almost inevitably the author's background and his desire for completeness render the treatment over-elaborate for the student and more suitable for the research worker, for whom the copious bibliography should be useful. Certain sections, such as that on transfer reactions, concern relatively new, expanding topics which would enhance an undergraduate course and which are almost unavailable at 'text-book' level. The book deals largely with the author's interests and, although this leads to a certain bias, it has the advantage that much recent work is collected together for the first time, and the writing shows considerable freshness of approach.

Certain diagrams and tables are difficult to follow, partly because there is a tendency to include excessive detail; and in some respects the text falls between two ideals. For example, in discussing Slater's theory, the reviewer feels that either a brief outline of the theory followed by its results should be given, or sufficient detail to enable the reader to work through an example for himself.

The general level of clarity of definition and readability is good, but occasionally, as in the all-important first sentence of the introduction, the style is obscure. The book is stimulating, good value and it deserves to be read. K. E. Howlett

Transistor Audio Amplifiers

By Richard F. Shea. Pp. xiii+219. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 52*s.* net.

JUNCTION transistors are rapidly replacing thermionic valves for audio-frequency amplification in many applications. Many circuit engineers with a particular interest in this topic will therefore be interested in this new book by R. F. Shea, which deals exclusively with it.

The book contains a mixture of theoretical and practical information. In common with most publications on transistors, it hinges on the use of 'equivalent networks'; one reason for this is that the internal feedback that occurs in transistors makes any other method of calculating their performance very difficult. It is a pity, however, that the author has not said more about the why and how of these networks before using them.

Almost a quarter of the book is devoted to listing manufacturers' data on a large number of American transistors. Scarcely any use is made of this material, which is, in any event, of little value in a book aimed at teaching fundamentals.

The book deals with the theory of the basic amplifier arrangements. It also has a chapter on pre-amplifiers where low noise and a reasonably high input resistance are required. Power amplifiers are discussed in some detail; in the case of class *B* circuits particularly, little is said about the relative merits of the various arrangements or how they can best be driven. Finally, there is a useful chapter on the design of four practical amplifiers.

This book will probably find a place on the library shelves at establishments interested in transistor circuits. Some engineers may find it of sufficient value on some topics to acquire their own copies.

D. D. Jones

An Introduction to Interferometry

By Prof. S. Tolansky. Pp. viii+223+5 plates. (London: Longmans, Green and Co., Ltd., 1955.) 21*s.* net.

THIS book on interferometry sets an example that might well be followed in other branches of physics, for it is not often that an acknowledged authority sees fit to write a text-book on his own subject for ordinary-degree students. It is refreshing to read a work at this level written by an expert teacher who is, at the same time, completely familiar with the practical details of the experiments and instruments he describes.

The subject-matter is necessarily far more than could normally be included in a degree course, but those who have to teach physical optics will find the book a source of inspiration for the particular sections of interferometry with which they may wish to deal. A great variety of interferometers is included, with emphasis on practical detail and the particular uses to which they are put in practice. The theory is elementary, and no elaborate mathematics is used.

The excellence of the book is somewhat marred by evidence of careless and hurried writing. Some of the earlier diagrams are poor (for example, in Figs. 2.11 and 5.7 rays are shown passing through lenses without deviation, and in Fig. 4.6 reflected rays do not obey the law of reflexion); punctuation is sometimes incorrect, and there is constant use of the adverbs 'thus' and 'hence' as conjunctions. I hope that there will soon be a second edition in which all the diagrams and the text match the very high standard of the contents. H. Lipson

The Mechanism of Evolution

By W. H. Dowdeswell. (The Scholarship Series in Biology.) Pp. ix+99. (London: William Heinemann, Ltd., 1955.) 6*s.*

THE concept of evolution has revolutionized biological thought during the past century, yet its full significance tends to be missed in school science courses, leaving a prevailing impression of something vast and rather unreal, which took place in the remote past. Mr. Dowdeswell's remedy is to incorporate with the classical evidence an understanding of the ways in which small evolutionary changes going on now, in wild populations around us, can be studied experimentally. The fact that many such experiments could be undertaken by the schools themselves makes it all the more stimulating.

After a preliminary survey of the historical background, variation is described in the light of modern genetics. There follows a discussion of natural selection and the effects of such factors as population size, continuity or isolation upon it. Examples drawn from many fields, including the author's own researches, lend intense vitality to the account. In conclusion, practical advice is given on experimental studies, and there is a summary of the present status of evolutionary theory, followed by a glossary and bibliography.

The book should prove immensely useful not only to the sixth-form boys and girls for whom it is intended, but also to teachers and first-year university students. Maurice Ashby

COLLOIDS AND THEIR BEHAVIOUR*

By Sir ERIC RIDEAL, F.R.S.

SINCE Graham's time there have been several attempts to define in a sufficiently embracing manner what is generally designated the colloidal state of matter. While the majority of workers in this field agree that form is an important factor, there is little doubt that Bancroft went too far in relying on this as the sole criterion, and McBain was too inclined towards a vitalistic view. The recognition that there exists between any two phases a third or interphase—the forgotten dimension of W. Ostwald—and that the properties and reactivity of matter constituting that phase or, as Sir William Hardy termed it, matter in the boundary state, differed from that in either of the bulk phases embracing it, leads us to attribute 'colloidal' properties to such manifestations, the *Kapillarchemie* of Freundlich. The greater the influence of matter in the boundary state on the system as a whole, the more manifest will be its colloidal properties. Evidently the two bulk phases must be so disposed relative to one another that interphase may constitute an appreciable fraction of the whole, and it is this interdispersion which is revealed in such a wealth of variety of forms.

Of fundamental importance in our approach to colloid science are the properties of liquid and solid surfaces.

Liquid–vapour and liquid–liquid interface are surfaces of equipotential and their free and total surface energies are readily measurable; in consequence, both the thermodynamic treatment and experimental investigations into the surface properties of capillary-active solutions and the behaviour of monolayers is well advanced. These investigations have added strength to the assumption that molecules at interfaces are orientated, and the unique properties of matter in the boundary state are in great measure due to this asymmetrical disposition. Detailed examination of monolayers both by means of surface pressure and surface potential measurements has presented us with examples in two dimensions of all the three well-known bulk states of aggregation, solid, liquid and gaseous, and as we might anticipate from the fact that orientation is one of the important features, we find in addition a large variety of orientated liquid or nematic states. The extension of the interphase in the bulk phases in these systems results in the formation of mists, foams and emulsions. In the former, the formation and growth of nuclei consisting of clusters of molecules, which in turn may either disintegrate again or re-arrange themselves to a more stable configuration and then proceed to grow by condensation of molecules taking place at a greater rate than evaporation, is a sequence of processes which, thanks to the investigations of Frenkel and Becker and Döring, have been capable of being analysed, while the experimental investigations on light scattering commenced by Tyndall in the Royal Institution has, as is well known, led to a wealth of information in such varied fields as coagulation at the hands of Whytlaw-Gray and La Mer and size and shape distribution by Debye.

We note that the growth of mists can take place either by further condensation of vapour or by coagulation of mist particles already formed. Our knowledge concerning the stability of emulsions is, in spite of their importance, still very incomplete. It is clear that since the interfacial free energy at the boundary of immiscible liquids is relatively great, two-component emulsions must be relatively unstable, and the first requisite of an emulsifying agent is to lower the interfacial surface tension. The distortion of a spherical drop leads to an increase in area, and in order to maintain a low interfacial tension more emulsifying agent must flow into the interface from one of the bulk-phase reservoirs. Further, if the emulsifying agent is present at the interface as a compressible two-dimensional liquid possessing a bulk-surface viscosity rather than as a vapour, a mechanical as well as a surface-tension brake is put on the extent of distortion of the sphere, and the stability of the emulsion is enhanced.

A simple picture of the process of curving an originally plane interface shows that the magnitude of the partition coefficient of the emulsifying agent between the two bulk phases serves as a criterion as to whether an oil-in-water or water-in-oil emulsion can be formed and where the inversion point is to be found. Attention may be directed to the possible significance of the inversion point in living systems. Among the more important factors contributing to the stability of colloidal suspensions are the electric charge and the extent of interaction of the colloid with its dispersion medium, that is, solvation.

Electric charges on colloid dispersions may come into existence through either surface ionization or through selective adsorption of ions from the medium. Pauli was a protagonist of the first view, regarding colloid particles as large ions, and his school has presented us with a wealth of analytical data in support of it. We can divide the distribution of the ions near the surface into two regions: those at or near the surface, confined in what is termed the Helmholtz or Stern double layer, and the diffuse or Gouy atmosphere, respectively. It is the latter that is responsible for electrokinetic phenomena. On adding electrolyte, the thickness of the diffuse layer decreases, the surface ionization is reduced and the adsorption of counter ions increased until coagulation and eventual precipitation ensue. The kinetics of this process have been examined and the results shown to be compatible with those anticipated from the effects of Brownian movement. By some, the ions held in the diffuse layer are regarded as being held by the type of restraint postulated by Donnan. On this view, the effective equivalent concentrations of multivalent ions would stand in the sequence M, $\sqrt[2]{M^{\cdot\cdot}}$, $\sqrt[3]{M^{\cdot\cdot\cdot}}$, an order given by the ordinary lyotropic series; but that physical or dispersive forces play an important part in such adsorption is clear from a consideration of the effectiveness with which wool can be dyed with the anions of many organic acids, or as seen in the following series of salts required to coagulate an arsenious sulphide sol:

---

* Substance of a course of three lectures for school teachers delivered at the Royal Institution on February 28, March 6 and 13.

Salt in millimoles/litre

Sodium chloride	51	Morphine hydrochloride	0·425
Guanidine hydrochloride	16 4	Neofuchsine hydrochloride	0 114

Ionic exchange at the surface of ionogenic colloids may result in the precipitated colloid containing more of the precipitating ion than is necessary for neutralization of the electric charge.

The results of adding electrolytes to the hydrous oxides in the sol or dispersed form are more complicated, for these colloids represent a transition between the hydrophobic and the hydrophilic systems. A sol of sufficient concentration of, say, ferric hydroxide undergoes gelation on addition of a small quantity of electrolyte. The sol particles must be regarded as networks of ferric hydroxide, containing, if made by hydrolysis of the chloride, a certain number of chloride ions with positive charges on the network. On reducing the charge, portions of the network are without charge and can adhere to one another. A very open structure is thus built up, containing both water of hydration and water within the network.

The network maintains a distended form partly owing to the residual charge and partly owing to the osmotic pressure maintained by the Donnan distribution. These gels, slowly and more rapidly, in the presence of large quantities of electrolyte, may become more and more compact and indeed may gradually lose their water of solvation as the network links join up by chemical interaction. Ferric hydroxide may be converted into goethite, Fe(OH)O. The conversion is also naturally accelerated by warming. During this process of contraction the residual aqueous phase separates, a phenomenon termed syneresis.

If, first, sufficient electrolyte be added to cause the sol to gelatinize, this rigid network may be broken up by agitation; and on allowing it to stand, those portions of the fibrils which are not charged may in virtue of their Brownian agitation recohere to form a rigid gel again. This is a thixotropic system and is well exemplified in, say, a 0·5 per cent suspension of the well-known clay bentonite. We note, on the progressive addition of an electrolyte, first the cessation of lateral Brownian agitation, then of rotational motion. At this stage the system is still thixotropic. Further addition of electrolyte produces aggregation and then true coagulation. Important examples of thixotropic systems are found in Nature, for example, protoplasm. If we examine the still more solvated systems such as the proteins, starches, agar agar in water and many polymers in non-aqueous systems, these do not flocculate when brought to the isoelectric point but may be caused to gel, in which form they are quite stable. But large quantities of salt are required to precipitate them. The contrast between the salt sensitivity of the suspensoids and the solvated colloids is made use of in the determination of the gold number. For many proteins small quantities of salt are required to render them soluble.

The stability of these highly hydrated colloids may be reduced by methods other than salting out. Thus we may dehydrate the solvated groups by addition, say, of alcohol, when the viscosity rapidly decreases and the sol becomes optically opaque and sensitive to flocculation by electrolytes (Fig. 1). We also find that there are substances which render the dispersion still more stable to electrolytes and counteract the sensitization produced by alcohols. These are peptizing agents and include such substances as acetamide, urea or sodium thiobarbiturate.

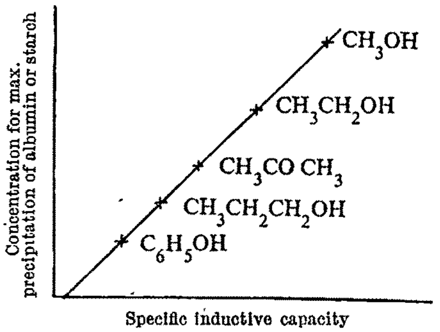

Fig. 1

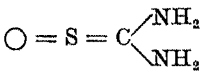
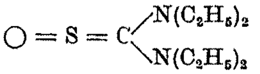
We can imagine with Katz that these substances are adsorbed by the colloid by covalent linking and alter the relative number of the polar and hydrated groups; thus



$$O = S = C\begin{matrix} NH_2 \\ NH_2 \end{matrix}$$

introduces two new polar groups on adsorption and is consequently a peptizing agent; but



$$O = S = C\begin{matrix} N(C_2H_5)_2 \\ N(C_2H_5)_2 \end{matrix}$$

or, say, tannic acid, renders the sol more hydrophobic and is thus a sensitizing agent. Just as the more hydrophobic metallic hydroxides can acquire a thixotropic state by careful adjustment of the extent of charge and solvation, so these more solvated systems, on sensitization by, for example, alcohols, can link up and form a separate but highly solvated phase, the so-called coacervates. These can also be formed by mixing two oppositely charged hydrophilic colloids together, for example, gelatine and gum arabic at a *p*H less than 4·8, when the gelatine is positively charged and the gum arabic negative. It is possible that the carefully balanced system sol $\rightleftharpoons$ coacervate $\rightleftharpoons$ gel plays an important part in the phenomenon of narcosis, a view long held by Claude Bérnard.

We have seen that the gel structure is produced by the interlocking of the solvated fibrils. It is pertinent to inquire how a solvent reacts with a dispersible solid, for example, a solid polymer. In general, these are partly crystalline and partly amorphous. The ratio of crystalline to amorphous phase is revealed by X-rays or by density determinations, varying greatly with the nature of the polymer and the state of tension and extension. We regard the fibrils as constituting both the amorphous as well as when adlineated the crystalline portion, the consequent structure being termed a fringed micelle.

In the amorphous portion the specific heat is greater than in the crystallite and possesses more entropy since the fibrils here can move. On addition of a solvent, the free spaces in the amorphous portion are filled, the movement of the fibrils is restricted and the entropy decreases; thus the preliminary wetting should be accompanied by a heat change. On adding more solvent, the swollen fibrils distend further and the crystallites commence to be pulled apart. At this stage the fibrils acquire more movement, the entropy increases and the process of imbibition goes on until, if the polymer be cross-linked, a steady and permanent extension is obtained. The conditions for equilibrium in such swelling are given by the thermodynamic relation:

$$\Delta H = \Delta F - T\Delta S$$

Since $\Delta F = 0$ at equilibrium, $\Delta H = -T\Delta S$. The heat of mixing of two liquids is given approximately by the difference in their cohesive energies:

$$\Delta H = KV\left(\sqrt{\frac{E_1}{V_1}} - \sqrt{\frac{E_2}{V_2}}\right)^2 (1 - V)^2$$

where E, the cohesive energy, is given by the latent heat of evaporation:

$$E = L - RT$$

The swelling powers and cohesive energies for a number of organic liquids when brought into contact with vulcanized rubber have been found to conform to this simple idea with remarkable exactness.

NEW SYSTEM OF ELECTRIFICATION FOR BRITISH RAILWAYS

By G. H. PLATT

King's College, University of London

THE recent announcement by the British Transport Commission of its decision to adopt the 50 cycles/sec. single-phase alternating current system for future main-line electrification of British Railways is of great interest to all in the electrical industry and of far-reaching importance to the nation as a whole.

The advantages of electrically operated railways are too well known to need elaborating here; but briefly they are:

(*a*) The greater power available enables faster services to be run and permits more frequent trains over any given track. This is most apparent in urban and suburban passenger services; but is equally important in handling the traffic over a busy main line.

(*b*) Above some particular traffic density, the cost per ton-mile is less than with other forms of motive power.

(*c*) Very much less coal is needed than for steam traction, owing to the much greater thermal efficiency of modern power stations than the steam locomotive. Moreover, the coal used in power stations is of inferior quality, and the use of nuclear energy will further save coal.

(*d*) The absence of smoke and dirt makes for general cleanliness.

Details of the British Transport Commission's scheme have already been published (March 1956). The new system is concerned principally with main-line electrification. The London Transport Executive and Southern Region systems are unaffected. Their form of power supply is the most suitable one for underground and suburban traffic, and the cost of converting that of the Southern Region is unwarranted for the amount of locomotive-hauled traffic involved.

For ordinary long-distance main lines, however, the conditions are quite different. The use of a.c. supply for electric railways offers great advantages from the transmission point of view in that a high voltage can be used on the overhead wire, and transformed down at the point of use, that is, on the locomotive. On the other hand, an a.c. motor has disadvantages for traction compared with its d.c. counterpart. A system using a.c. of low frequency (15–25 c./s.) is in fairly wide use, but has the disadvantage of requiring its own generating plant and supply network, entirely separate from those of the public supply, or else expensive frequency-changing substations employing rotating machinery. Rotating machines for the conversion of a.c. to d.c. have long been rendered obsolete by the development of the mercury arc rectifier and the majority of electric railways using alternating current to-day convert the a.c. supply to d.c. at 1,500 or 3,000 volts in substations alongside the tracks. With main-line locomotives this means that heavy currents have to be collected. The weight of copper in the overhead system is thus considerable, the supports must be proportionally strong and the total cost is high.

By feeding the contact wire with a.c. at 25 kV. the current to be collected is greatly reduced and the whole overhead system can be made much lighter and cheaper. In addition, substations can be placed much farther apart so that fewer are needed, and furthermore, the substations themselves are simpler and cheaper, containing only static transformers and switchgear. This is an important advantage, as the cost of the fixed installations does not vary greatly with the traffic density. Hence the use of a.c. supply may make it financially justifiable to electrify lines which would otherwise be uneconomic due to their lighter traffic.

In this connexion a special survey of the proposed Euston–Manchester–Liverpool route has shown that some startling economies will be effected by the use of a.c. This system will require twelve substations only instead of seventy for d.c., and need 68 per cent less copper and 17 per cent less steel for the overhead equipment. An additional saving in this case is that only seventeen instead of two hundred and fifty miles of 33 kV. feeder lines will be necessary to take the current from the Central Electricity Authority.

This change in supply has been made possible largely by the progress in rectifier design, which has now made it practicable to carry the rectifiers on the locomotives themselves. Those already in service mostly utilize mercury valves of the 'Ignitron' or similar type; but successful trials have been run recently on British Railways by a motor-coach employing a germanium rectifier. This is an important advance in this field.

The new system also offers greater scope for development in design and technique than other systems. With d.c. supply, the motive power must of necessity employ d.c. motors; but by bringing the a.c. right into the locomotive the maximum freedom is given for the development of its design. Locomotives with rectifiers, various types of converters and straight a.c. motors are in use experimentally in France, and some of these have been found to have special advantages for certain kinds of traffic.

The low-frequency, single-phase a.c. commutator motor is considered by some to have better characteristics than the d.c. machine for main-line work, and the development of the former to operate satisfactorily on 50 c./s. has made considerable progress during the past few years in France. This type may yet become a serious rival to the d.c. series machine.

Up to now, however, the rectifier locomotive has given the most promising results, and has been found to have unexpected operating advantages over even its d.c. rival. On the Valenciennes–Thionville line, B_0—B_0 type mixed-traffic locomotives with 'Ignitron' rectifiers and having 84 tonnes adhesive weight haul freight trains of 1,400 tonnes, whereas the absolute maximum loading of a modern 1,500-V. d.c. locomotive of the same type and weight would be 900 tonnes only. This is due to improved adhesion characteristics at starting and at low speeds.

The motors used in rectifier locomotives are of the d.c. series type, specially designed to work satisfactorily on the pulsating output from the single-phase rectifiers. Biphase or 'full-wave' rectification is used, the output from which can be considered as a smooth d.c. voltage having superimposed on it an alternating e.m.f. of comparable magnitude and a frequency of 100 c./s. This introduces problems of commutation and heating in the motors; but by paying special attention to the design of the motors and including smoothing chokes in the circuit the difficulty can be overcome satisfactorily. With the ordinary d.c. system the problem does not arise, since rectifiers having six or more phases are used and the a.c. component or 'ripple' is in consequence insignificant.

The cost of the rectifier locomotive, according to the French figures, is comparable with a d.c. machine of the same rating, both in first cost and maintenance. Allowing for the improved performance, the rectifier machine shows a considerable economy in operating a given service. The use of semiconductor rectifiers in the future should show an even greater saving. The above-mentioned British survey shows that sixty fewer locomotives will be needed for these services.

The provision of sufficient clearances for a contact-line voltage of 25,000 volts is not easy in Britain. In some tunnels the cost of providing clearances would be prohibitive, and therefore it is proposed to employ a much lower voltage, namely, 6,600 volts, over certain sections, combined with the use of dual-voltage equipment.

The taking of large amounts of single-phase power from the public supply network suggests problems of unbalance on the three-phase system. Experience in France has shown that any disturbance has remained within acceptable limits, and no trouble is anticipated in Britain with its more heavily-loaded grid. The proposed scheme has the full concurrence of the Central Electricity Authority.

In addition to its major advantages, the use of a.c. supply simplifies very considerably the supply of power to locomotive auxiliaries, train lighting and heating, etc., a single transformer sufficing to provide supplies at any voltage required.

It is evident that the British Transport Commission's choice of the 50 c./s. alternating current system is based on a balanced judgment of the many factors involved. The Commission's readiness to profit by the latest technical developments is to be highly commended.

I would like to thank the Chief Electrical Engineer of the British Transport Commission for placing information relating to the proposed developments at my disposal.

A NOTABLE BIOCHEMICAL JUBILEE

IN 1906 Arthur Harden and William John Young, of the Lister Institute of Preventive Medicine, made two communications to the Royal Society of London on the alcoholic ferment of yeast juice; the first described the effect of phosphate on the rate of fermentation of glucose, and the second the separation from the juice by ultrafiltration of an inactive residue which could be re-activated by a soluble, heat-stable coenzyme in the filtrate.

Harden's experiments arose out of an attempt made with Allen Macfadyen to produce an anti-enzyme by the injection of yeast juice into animals, in the course of which it was found that normal serum increased the fermentation of glucose by yeast juice. In further experiments, Harden and Young fortunately adopted a volumetric instead of a gravimetric method, which enabled them to follow the rate of production of carbon dioxide continuously; they found that the filtrate from boiled yeast juice also increased the fermentation, with an initial rapid evolution of carbon dioxide, proportional in amount to the volume of juice added, and a prolongation of fermentation at a slightly higher basal rate. The effect was traced to the phosphates present in the juice, the extra carbon dioxide corresponding to one molecule for every atom of phosphorus added as orthophosphate; after the fermentation the phosphate was present in a form not precipitated by ammoniacal magnesium citrate, and presumed to be as an ester. The ester was afterwards identified by Young as fructose diphosphate; later, Harden and Robison found that a hexose monophosphoric ester was also formed which was shown by Robison to be an equilibrium mixture of glucose, fructose and mannose esters.

Harden and Young also dialysed the fresh juice, to find out the effect of the complete removal from the juice of the dialysable substances passing into the filtrate of boiled juice. They used for this purpose the rapid method of ultrafiltration under pressure through a filter of gelatin supported in the pores of a Chamberland filter candle, which had been devised by C. J. Martin, then director of the Lister Institute. In this way, the juice was separated into a residue and a filtrate, each of which was itself incapable of fermenting glucose, but which together fermented it as actively as the original juice. Since soluble phosphates did not activate the residue, it was concluded that the filtrates contained a distinct factor, to which the name 'coenzyme' and later 'cozymase' was given.

Their work was simple but precise, and its very precision was perhaps a bar to their further elucidation of the phenomenon of phosphorylation. Harden perceived that inorganic phosphate was necessary for the rapid rate of fermentation, that is, the process of esterification was necessary; but it seemed that the ester formed (hexose diphosphate) could not be an intermediate, since it was only fermented very slowly by the juice. Harden and Young considered that a coupled reaction occurred:

$$2C_6H_{12}O_6 + 2H\mathit{R}_2PO_4 \rightarrow 2CO_2 + 2C_2H_6O + 2H_2O + C_6H_{10}O_4(PO_4\mathit{R}_2)_2$$

in which by the phosphorylation of one molecule of sugar the breakdown of a second molecule was induced; when all the inorganic phosphate was esterified, the rate of fermentation fell to the basal rate, dependent for a supply of phosphate on the slow hydrolysis of the phosphoric esters.

It was not until 1945 that Meyerhof showed that the two phases were due to a destruction of the adenylpyrophosphatase of yeast during the preparation of the juice, so that the coupled reaction:

3-Glyceraldehydephosphate + phosphate + cozymase ⇄ 1-3 diphosphoglyceric acid + dihydrocozymase

1-3 Diphosphoglyceric acid + adenosine diphosphate ⇄ 3 phosphoglyceric acid + adenosine triphosphate

came to a halt for lack of the phosphate-supplying mechanism of the apyrase:

Adenosine triphosphate → adenosine diphosphate + phosphate

Harden's facts, however, were incontrovertible and induced an autocatalytic fermentation in the science of biochemistry the course of which need not be recapitulated here. Though he realized the fundamental nature of his work, he was habitually restrained and would have thought it regrettable hyperbole to say to his colleague in 1906: "This day we have lighted such a candle in England as I trust shall never be put out". But it is no exaggeration to say now that their work is the source, reflected and amplified by many later workers, of our understanding of intermediary carbohydrate metabolism and many other phosphorylation mechanisms in animals, plants and micro-organisms.

IMMUNOLOGICAL TOLERANCE

A MEETING was held on March 8 at the Royal Society on the subject of "Immunological Tolerance", under the leadership of Sir Macfarlane Burnet. Following the definition of Billingham, Brent and Medawar, immunological tolerance is a specific weakening or suppression of reactivity caused by exposure of animals to antigenic stimuli before the maturation of the faculty of immunological response. In his opening paper, Prof. P. B. Medawar (University College, London) referred to the experimental demonstration of tolerance against such varied antigens as the erythrocyte agglutinogens, the tissue antigens responsible for transplantation immunity, bacterial antigens and purified proteins. Marked differences are found between the first two of these antigens: the erythrocyte antigens are stable, cytoplasmic, and elicit a transient gamma-globulin response, whereas the unstable, nuclear, tissue antigens elicit a permanent state of heightened graft resistance mediated by leucocytes rather than serum.

In contrast to the suppression of reactivity brought about by agents such as cortisone or radiation, tolerance is specific: the response to one antigen is suppressed without altering the response to others. Another essential property is that the suppression is central, acting on the tissue producing the antibody. Tolerance differs in this respect from immunological paralysis, or the enhancing of tumour growth by antiserum or tissue extracts. A comparable specific and central suppression of the immunological response has been demonstrated by Chase in the inhibition of sensitization to simple organic compounds by prior oral feeding. Medawar then returned to the subject of the biological implications of immunological tolerance[1].

In a paper on "Erythrocyte Antigens and Tolerance Phenomena", R. D. Owen (California Institute of Technology) drew two conclusions from his earlier work on stable erythrocyte mixtures in twin cattle. From the observation that the antigenic types derived from each twin occur in equal proportions in the blood of each twin, it follows that no selective pressure is exerted in favour of hæmatopoietic tissue of native origin, and that tolerance is therefore complete. From the observation that no more than two types of cell are found in twins which differ by several antigens (with the exception of *J*), it follows that sub-cellular transformations do not occur, and that hæmatopoietic cells are in this sense fully autonomous. Attempts to mimic the chimerism of twin cattle in rats by means of parabiosis have been unsuccessful; but Ripley has produced a similar condition by injection of embryonic rats with embryonic liver and spleen cells through the chorionic blood vessels. Chimeras have also been produced in rats after injection of hæmatopoietic tissue into irradiated recipients, by Lindsley, Odell and Tausche. Owen then described his own work on acquired tolerance in man, where past exposure to *Rh* antigens *in utero* weakens the adult antibody response. *Rh*-negative women who complete three or more *Rh*-positive pregnancies without developing antibodies tend to have *Rh*-positive mothers. This tolerance is, however, not associated with a reduced incidence of erythroblastosis. Owen finally described an effect of injection of human erythrocytes into new-born chickens. The antibody response of the recipients as adults is delayed, weakened and tends to the production of incomplete antibody.

B. Cinader and J. M. Dubert (Lister Institute and Institut Pasteur) gave an account of their joint work on "Specific Inhibition of Response to Purified Protein Antigens". New-born rabbits were injected with highly purified human albumen, and litter mates left as controls. When challenged with the same antigen as adults, the controls produced antibody detectable by a gel-diffusion technique, and also by agglutination of tanned erythrocytes coated with antigen. The animals injected at birth failed to produce antibody, constituting an example of actively acquired tolerance. Tolerance of the injected animals was also exhibited in experiments with human albumen labelled with radioactive iodine. The labelled protein was eliminated slowly and continuously from the tolerant animals, in contrast to the controls, which exhibited a sharp rise in the rate of elimination as the immune response developed. Tolerance in this instance was shown to be specific, by means of cross-tests with tobacco mosaic virus and also diazotized human albumen. The diazotized human albumen provides a refined demonstration of specificity, since it is an antigen which normally elicits antibodies of two distinct types, specific either for the diazo group or for the albumen. Those tolerant animals which responded to the diazotized human albumen produced antibody only against the diazo group, as could be shown by absorption tests with human albumen. In a single animal, administration of diazotized human albumen appeared to weaken the tolerance to normal albumen, indicating that the state of tolerance can itself be modified experimentally.

Applications of immunological tolerance were described in papers entitled "Tolerance of Ascites Tumour Cells", by H. Koprowski (Lederle Laboratories, New York), and "Acquired Tolerance of the Rous Sarcoma Agent in Turkeys", by R. J. C. Harris (Chester Beatty Research Institute). Koprowski was able to obtain, from two transplantable mouse lymphomas, lines that would grow in normally resistant mouse strains; and from a rat hepatoma he obtained a line which would grow in mice. The transformation was made by inoculation of tumour cells into unborn mice of the prospective host strain, thus inducing a state of tolerance which enabled the tumour to grow progressively. The tumour masses which developed after birth served to start the transformed line of tumour, if necessary re-inoculating fœtal mice to complete the transformation. The adaptation of the transformed tumour lines to their new hosts was incomplete, as judged by the dosage of tumour cells needed to kill the new hosts as compared with hosts of the strain of origin. The transformed mouse-tumour lines appeared to retain antigens characteristic of their strains of origin, as indicated by adoptive immunization tests. The rat tumour retained the characteristic rat *V*-chromosomes, and could be transplanted back into rats. In tests with a variety of animal viruses, the transformed-tumour lines appeared to provide better hosts for virus multiplication than the original lines, and to be more susceptible to oncolysis by viruses.

Turkeys which had been rendered partially tolerant to chicken antigens were used by Harris, in an attempt to separate the Rous sarcoma agent from chicken antigens. If inoculated soon after hatching with chicken antigens, a proportion of turkeys are rendered susceptible to the Rous sarcoma virus and other non-virus chicken sarcomas. Live blood cells, blood cells killed by freezing or heating, or skin grafts, are all active for this purpose as chicken antigens. While growing in susceptible turkeys, the Rous sarcoma progressively loses its content of virus infective in chickens. This may indicate a conversion of the virus to the turkey antigenic type; but since virus assays were not also carried out in turkeys, it may instead indicate a decrease in the virus content of the tumour cells. After a single passage back into chickens, the sarcoma regains its full content of virus infective in chickens.

Parallel papers were presented by M. Hašek (Czechoslovakian Academy of Science) on "Tolerance Phenomena in Birds", and by R. E. Billingham and L. Brent (University College, London) on "Analysis of Tolerance induced in Newly Hatched Turkeys and Chicks". Work in London and Prague has shown that tolerance is readily produced in birds by the introduction of foreign cells into the embryo, intravenous injection and parabiosis being particularly effective methods. Hašek concentrated on the manifestation of tolerance as a suppression of hæmagglutinin production, and Billingham and Brent as a prolongation of the survival-time of skin grafts. In order to weaken or suppress reactivity to skin homografts, Billingham and Brent find that live, nucleated cells are essential. According to the criteria of hæmagglutinin suppression and prolonged graft survival, tolerance is produced more readily within than between species. The combinations of species tested were between chicken, turkey, duck, pheasant, goose, guinea fowl and pigeon. As expected on Darwinian principles, they find that tolerance produced between some strains of poultry is weaker than between others. The degree of tolerance which could be produced between species appeared to vary in accordance with their systematic relationship.

Induction of tolerance by intravenous injection of antigens into new-born chickens or mice was also described by Billingham and Brent. This method proved to be more economical than injection into the embryo. Nearly half the chickens injected with blood from another strain exhibited a degree of tolerance, although only a small proportion of skin homografts on new-born chickens take permanently This discrepancy is ascribed to the delay in vascularization of the grafted skin.

---

OBITUARIES

Prof. F. Riesz

The distinguished Hungarian mathematician, Friedrich (Frigyes) Riesz, died recently. He was born on January 22, 1880, at Györ, and studied at Zurich, Budapest, Göttingen and Paris, taking his doctor's degree at Budapest in 1902. In 1911 he was appointed to a supplementary professorship at Kolozsvár (Cluj), becoming Professor Extraordinarius in 1912 and Professor Ordinarius in 1914. In 1919 Riesz moved with his university to Szeged, and in 1945 he was appointed to a chair in Budapest. In 1922 he became editor of a newly founded periodical, the *Acta Scientiarum Mathematicarum* of Szeged which quickly established a distinguished place for itself among the world's mathematical journals.

Riesz was one of the pioneers of functional analysis and we owe to him many of the fundamental ideas of the subject, which were later incorporated in an axiomatic formulation by S. Banach and his collaborators. Riesz's principal contributions may be summarized as follows: the Riesz–Fischer theorem (1907) on the equivalence of Hilbert's space o sequences of convergent sum of squares with the space of functions of summable square, which is the mathematical basis of the equivalence of matrix mechanics and wave mechanics; the Stieltjes integral representation for linear functionals on the space of continuous functions (1909); the theory of L^p spaces (1910); the first systematic discussion of analytic functions of operators (1913); the definition and properties of general completely continuous operators (1916); and the foundation of the theory of partially ordered vector spaces (1928). In 1952 there appeared the "Leçons d'analyse fonctionnelle", written jointly with B. Sz.-Nagy, and easily the most readable introduction to functional analysis that has yet appeared.

Riesz constantly strove to simplify the presentation of the theory of the Lebesgue integral; he introduced the systematic use of step functions (1912), and he proved (1931) the famous 'rising sun lemma', which leads to an easy proof of the differentiability almost everywhere of a monotone function.

He was one of the creators of the theory of subharmonic functions. Other fields to which he contributed include the theory of functions analytic in the unit circle, orthonormal series, inequalities and ergodic theory. He gave several proofs of the fundamental spectral theorem in Hilbert space. An early paper (1908) on topology contains ideas (bicompactness, the filter theory of limits) that had to wait until the late 1930's for their full development.

Riesz's work is characterized throughout by simple and powerful ideas and by lucidity of presentation; his papers are always easy to read. He never generalized for generalization's sake; his aim was always to put the main ideas in a setting that would illustrate their significance and their power as vividly as possible.

F. Smithies

Dr. Eugene C. Crittenden

Eugene Casson Crittenden, formerly associate director of the United States National Bureau of Standards and for many years chief of its Electrical Division, died in Garfield Hospital, Washington, D.C., on March 28 at the age of seventy-five.

After graduating in 1905 and a period of postgraduate work and teaching, all at Cornell, Dr. Crittenden joined the National Bureau of Standards in 1909 and was assigned to the photometric laboratory, where he was afterwards to make many important contributions towards the establishment of modern photometric units, standards and methods of measurement. During 1921–46 he was chief of the Electrical Division and thus also became responsible for work which, in collaboration with other national laboratories, led to the replacement of the obsolescent system of international electrical units by the present system of absolute electrical units. Under his leadership the Division expanded substantially, and sections for research in radio and electronics were established which eventually became major organizational units of the Bureau—for example, the Central Radio Propagation Laboratories at Boulder, Colorado, and the former Ordnance Development Division, now the Diamond Ordnance Fuze Laboratories of the Department of the U.S. Army. In 1933 Dr. Crittenden was made assistant director of the Bureau and became concurrently responsible for supervision of its over-all research and testing activities; and in 1946, when the title was changed to associate director, he assumed the full-time responsibilities of this post, which he held until he retired in 1950. For his outstanding services to the Bureau he was awarded in 1949 one of the first Gold Medals of the Department of Commerce for Exceptional Service. He continued to act as a consultant to the Director of the Bureau until the onset of his last illness a few months ago.

Dr. Crittenden is best known both in his own country and internationally for his many activities and services which, combined with those already mentioned, played an important part in the developments which led to the international adoption in 1948 of the present electrical and photometric units and standards. He was vice-president of the International Commission on Illumination during 1939–48 and president of its U.S. National Committee from 1928 until 1935. During 1946–54 he was the member for the United States on the International Committee of Weights and Measures, of which he was vice-president from 1950 until 1954, and he had been a member of this Committee's advisory body for electricity and photometry since 1933. He also participated in the work of the International Organization for Standardization and the International Committee of Legal Metrology. Dr. Crittenden was for many years on the Standards Council of the American Standards Association, of which he was chairman during 1945–48, and in his time he served as president of the Illuminating Engineering Society, the U.S. National Committee of the International Electrochemical Commission and the Optical Society of America, as well as associate editor of the *Review of Scientific Instruments*. He also participated in the work of the American Society for Testing Materials, the American Institute of Electrical Engineers, the American Institute of Physics and the National Research Council.

Dr. Crittenden will long be remembered by his former colleagues on international committees, for he always brought to their deliberations wise counsel based on great knowledge and experience and expounded with good humour. Photometry was the primary interest which eventually led him to become a renowned exponent of international collaboration in all matters concerned with metrology. He is survived by his wife, formerly Norma M. Snyder, a daughter and a son.

H. Barrell

Dr. A. L. Stern

Arthur Landauer Stern died suddenly on April 26 at Chorley Wood at the age of eighty-eight. He was born on May 6, 1867, the eldest of seven children of Moritz and Fanny Stern, of Birmingham. At King Edward VI High School he was a Foundation Scholar; and in 1887 from Mason College he obtained honours B.Sc. (London). He was then Tangye Research Scholar and personal assistant under Sir William Tilden, working on compounds of phosphorus. After that, under Dr. Cornelius O'Sullivan, he worked on chemical problems of fermentation and brewing, and soon became chemist and brewer at Messrs. Bass, Ratcliffe and Gretton, under O'Sullivan. An early piece of work was to show that glucose from various sources was the same substance, and thus he helped to lay one of the foundation stones of modern organic chemistry. He obtained his D.Sc. (London) in 1894.

On the death of O'Sullivan in 1906, Stern succeeded him as head brewer at Bass's New Brewery. He reorganized the research, with prescience concentrating on the biological side (Dr. Arthur Slator was then his chief assistant). Under his direction, the rate of multiplication of yeast cells was shown to be subject to simple mathematical laws. On the industrial side, a series of researches revolutionized the maturation of beer. It is forty years since Stern substituted metal tanks with single-feed cylinders in the racking room instead of the old single wooden casks; and his method has now become standard practice. Many technical processes were influenced by him, from the better use of fuel in breweries to the bottling of beer and its dispatch overseas so that "Bass" should arrive in perfect condition in diverse climates. Incidentally, he, under O'Sullivan, brewed the famous King's Ale of 1902.

Stern's brewery was a happy place. He was not only a master brewer, but also had happy relations with his staff, and took a personal interest in them and their families. He was a man of wide interests, and although he retired early, he never lost contact with scientific affairs.

He had a very happy married life, saddened only by his wife's death last year. He leaves seven children, all of whom went to universities, four of them following scientific careers; his eldest grandchild is about to enter Cambridge to read science.

Mr. Harold Picton

Harold Picton, who died on March 21 in his eighty-ninth year, will be remembered for his contributions to science, education and international understanding.

Picton was a son of the Rev. J. A. Picton, Unitarian minister and M.P. for Leicester, and grandson of Sir James Picton, of Liverpool. After graduating at University College, London, he worked in Sir William Ramsay's laboratory. With S. E. Linder he published a series of papers on colloidal solutions. Sols of arsenious sulphide were prepared in various grades down to one in which the submicroscopic particles passed through porous pot and diffused, yet still scattered light, giving the Tyndall effect. Picton and Linder were the first to show the migration of such particles in an electric field, the arsenious sulphide moving to the anode and ferric hydroxide to the cathode. They studied the precipitation of these sols by electrolytes and showed the presence of the positive ion in the precipitated arsenious sulphide. The efficiency of the electrolyte as coagulator was also related to the charge on the positive ion. This is known as the Hardy–Schulze Law, but, as Prof. W. C. McC. Lewis wrote, it "might perhaps more legitimately be known as the Schulze–Linder–Picton–Hardy Law". This work undoubtedly laid the foundation of much of the modern view of suspensoid colloidal systems.

In 1900, after a few years as science master at Parmiter's School, Picton joined his friend, the Rev. J. E. Bennett, who had opened a small residential school, Clacton College, and shortly afterwards he succeeded him as headmaster. This was a remarkable school which anticipated many modern trends in education. A family spirit was developed both in and out of the classroom. Discipline was strict but kindly, and was based on rules laid down by an elected school council. The physical, mental and spiritual aspects of personality were provided for in a well-balanced whole. Games were played but were not over-emphasized, and boys were encouraged to take up other interests such as gardening, photography, and the study of church architecture and of prehistoric remains. A number of worked flints and mammalian bones and teeth were collected from the Pleistocene deposit on the Clacton foreshore and this section of the school museum was afterwards presented to Charterhouse School.

From his mother (née Jessie C. Williams), who was brought up in Hamburg, Picton acquired a deep love of Germany. From 1914 onwards he strove to promote a better understanding between the Germans and the British. In five books published between 1918 and 1948 and many other writings he stressed the better elements in German life and culture. His "Early German Art and its Origins" (1939) was an important work. For six years he lived near Berlin but returned to England in 1934 after the rise of Hitler. From that time he exposed the horrors and dangers of the Nazi dictatorship; but always insisted that the whole German nation should not be condemned for the crimes of the Nazis. He worked untiringly to help refugees from Germany.

Harold Picton was a man of vigorous and many-sided personality to whom men were more important than systems. He had a genius for friendship and he gained the affection as well as the admiration of his pupils, who will never forget the debt they owe him. He did not marry but adopted a son, who survives him. G. M. Bennett

Dr. Harry J. Deuel, jun.

Dr. Harry J. Deuel, jun., whose death at the age of fifty-eight occurred on April 17, had been an active force in the field of nutrition for more than a quarter of a century, his major interest being the biochemistry of lipids. His group at the University of Southern California has established a vast amount of biological data on the digestibility of fats and the lipid composition of the tissues of different animals under varying experimental conditions. This quantitative information has been, and will continue to be, of great value to innumerable workers in this field.

It is not only as an accumulator of facts that Dr. Deuel will be remembered; he also made notable contributions to advancing knowledge, especially in connexion with the composition of cerebrosides, the conversion of carotene to vitamin A, the nutritional importance of dietary fat and the effect of hormones on lipid metabolism. He had a wide knowledge and interest in all work in the lipid field, and many will recall happy hours of argument and discussion in which he took a leading part. This width of experience found expression during the past few years in his writing "The Lipids; their Chemistry and Biochemistry", two volumes of which have already been published. The third and last volume was nearing completion at the end of last year. This work is likely to become established as a standard work in this field—a fitting memorial to its author.

Harry Deuel took great delight in meeting people. As a Fulbright Fellow at Cambridge during the past year, he was able to renew many old friendships and to make many new ones. He carried through an active programme of lectures and visits, both in Britain and on the Continent. Those who had the privilege of meeting or hearing him during this past year will find inspiration, not only from the scientific contributions he made on many occasions, but also from his immense courage and fortitude. He was a man that so many of us were happy and proud to have known. A. C. Frazer

NEWS and VIEWS

Anatomy at Cape Town: Prof. M. R. Drennan

After forty-three years of almost continuous service to the University of Cape Town, Prof. M. R. Drennan retired from its chair of anatomy at the end of 1955. He arrived in South Africa from Ayrshire in 1913, the year of the first discovery of a fossil human skull, the Boskop skull, in South Africa, and no single personality has impressed his stamp more profoundly upon the first medical school to be established in South Africa. Not only as a contributor to Cunningham's "Anatomy", but also as the author of his own concise text-books on osteology, embryology and physical anthropology, his name is familiar to medical students throughout the Commonwealth. Among some thousand registered medical graduates directly influenced and inspired by his teaching are such figures of eminence as Thomas J. Dry, of the Medicine Section of the Mayo Clinic, Sir Solly Zuckerman, of Birmingham, and David Slome, of the Royal College of Surgeons of England. Amid the spectacular South African discoveries in physical anthropology of his generation, Drennan's shine with characteristic brilliance. His recognition of the Boskop fossil type as still extant in a Hottentot being dissected (1924), of the Australoid fossil skull from the Cape Flats (1929), of pedomorphism in the pre-Bushman Plettenberg Bay skull (1931), of the Neanderthaloid features in the Florisbad skull (1935) and of the Rhodesian affinities of the Saldanha Bay skull (1953) are classical contributions to prehistory. His collection of extant, recent and fossil human material from the southern extremity of the Old World land mass established a crucial centre of research that has been steadily illuminating human anatomy and history in Africa from the Middle Stone Age to the modern era. In approximately a hundred publications, Drennan's originality has ranged over topics historical and educational as well as the more strictly anatomical and surgical. As past president of the South African Archæological Society, member of the Historical Monuments Commission from its inception, fellow and council member of the Royal Society of South Africa, director of the South African Museum and in numerous other professional and public capacities, he has given and will doubtless continue to give unremitting service in many capacities to South African science.

Prof. L. H. Wells

Dr. L. H. Wells, who succeeds Prof. M. R. Drennan, is returning to South Africa, whence he went as senior lecturer in physical anthropology to the Department of Anatomy at the University of Edinburgh in 1951. Educated at St. John's College and the University of the Witwatersrand at Johannesburg, he showed an early leaning towards anatomy by graduating M.Sc. with a thesis entitled "The Foot of the South African Native", and by his appointment first as a graduate demonstrator and later as a junior lecturer in anatomy, prior to taking his medical qualification, by which time he already had a number of publications to his credit. His early interest in physical anthropology and human and comparative palæontology, stimulated by the head of the Department of Anatomy at Johannesburg, Prof. R. A. Dart, and by the work of the late Robert Broom, has continued unabated to the present time, being recorded in a long series of papers which report the results of studies on a wide variety of subjects ranging from the peroneus tertius muscle of the baboon and the anatomy of the Bushman to human remains of the Dark and Middle Ages in south-east Scotland. The appointment of an anthropologist of Dr. Wells's calibre to the chair at the University of Cape Town will undoubtedly further the study of anthropology in Africa, while bringing him into closer touch with the important discoveries of fossil primate remains which continue to be made on that continent.

The Perkin Centenary

To mark the centenary of W. H. Perkin's discovery of the first synthetic dye, the *Manchester Guardian* has included a supplement in its issue of May 7 in which various contributors discuss the many developments that have resulted from this great event made when organic chemistry was still in its infancy. The first article is a personal recollection of Perkin by his nephew, Mr. Arthur H. Waters, who relates how he can remember his uncle back to about the year 1880 (when Mr. Waters was six years old). The article is a charming reminiscence of a man who, though his name to the outside world was illustrious, was to his kith and kin a simple, kindly soul—a religious man deeply interested in social welfare, temperance and evangelism; a great lover of children; a vegetarian; a keen recruit to the ranks of bicyclists in the early nineties; and a man who scarcely ever mentioned chemistry in the family circle. Mr. Waters's contribution is followed by one by Prof. W. Bradley (Department of Colour Chemistry and Dyeing, University of Leeds) on Perkin's scientific work and life. Two more articles continue in the biographical vein: "The Perkin Family and the Textile Industry", by R. G. Fargher (director of research and development, Samuel Heap and Son, Ltd.), in which are discussed the parts played in the textile industry by two of Perkin's gifted sons, namely, William Henry and Arthur George; and "Pullar and the Dyers' Reaction", by J. L. Crockatt (director and general manager, J. Pullar and Sons, Ltd., Perth), in which is retold the story of Perkin and the young dyer, Robert Pullar, of Perth. The remaining three articles deal with the more modern industries that have grown up as a result of Perkin's work. Under the heading "A More Fragrant World", Paul F. Spencer (chief chemist, Cusson Sons and Co., Ltd.) discusses synthetic odours and flavours, and in a rather longer article, "Raw Materials derived from Coal", L. W. Blundell (president of the National Benzole and Allied Products Association) writes on the importance of the residues from gas-works. The last, and longest, article is by Frank L. Rose (research manager, I.C.I. (Pharmaceuticals), Ltd.) on "Perkin's Influence on Medicine: the Development of Drugs and Antibiotics", a field in which the name of Ehrlich, working first with methylene blue and congo red, stands head and shoulders above the rest. Of all the lines developed from Perkin's dye, this is perhaps the one in which the most amazing developments have been made; certainly it has been the one most beneficial to mankind.

Supply of Scientists and Technologists in Britain

In his presidential address to the Institution of Chemical Engineers on "The Technological Awakening", given on April 24, Mr. J. A. Oriel welcomed the Government's new awareness of the value of technology, which he thought was due largely to the work of the chemical engineer during the past thirty-five years, and he urged that the situation should be examined constructively and with a view of helping rather than of controversy. He deprecated controversy over the relative merits of an education in the arts or in the sciences. This is a passing phase, although at present there are too many 'scientific illiterates, and it is regrettable that we should not have at the head of affairs, at a time of great technical improvements, more men with technical imagination capable of inspiring those working under them. Nor did Mr. Oriel think there is much advantage to be gained by comparing the position in Britain with that in the United States and the U.S.S.R. We do not wish to follow the U.S.S.R. in forcing men to adopt scientific or technological careers; but we cannot deny that we force men into National Service, and the Government has not grasped the seriousness of diverting from their profession when they are badly needed those chosen because of their ability for special training in science and technology.

Mr. Oriel thinks that the number of boys reading science has already increased, and that the quality will also improve. He believes that the technological sub-committee of the University Grants Committee will provide the necessary guidance and impetus to technological education, but pointed out that the universities can help to improve the status and outlook of teaching staff in the technical colleges by inviting their assistance in research and allowing more research carried out at the technical colleges to rank for the preparation of Ph.D. theses. He also suggested that universities hold on to their graduates too long; a university should retain only a very small number of those who have obtained their first degree, and only then after satisfying itself that they are really men who will benefit by a period in research, which normally, Mr. Oriel suggested, should be pursued at a different university. In general, the undergraduate after three or four years should move into industry or teaching, and those clearly designed for first-grade technologists should move elsewhere to a college also open to men who had already spent from two to five years in industry. In such institutions we may expect to find the interchange of ideas and techniques that will really make Britain a leader in quality of technologists. As regards the technical colleges, where the expansion in technical education will come, Mr. Oriel pointed out that the municipal or regional patriotism of the local education authority can be a source of strength as well as a weakness, and he appealed for full support of the 'sandwich' system by members of the Institution who as managers are in a position to help. Given such support and a right attitude by parents, teachers and university professors as well as industry, Mr. Oriel sees no reason why Britain should not double its output of well-trained scientists and technologists within five years.

Physical Society's Handbook of Scientific Instruments and Apparatus

THE "Handbook of Scientific Instruments and Apparatus, 1956 Exhibition", published in connexion with the fortieth annual exhibition of scientific instruments and apparatus of the Physical Society, to be held in the Halls of the Royal Horticultural Society, London, during May 14–17 (see *Nature*, April 7, p. 653), is not only a detailed catalogue and guide to the exhibits but is also a valuable reference book and useful indication to recent progress and development in the design and production of British scientific instruments and apparatus (pp. xvi + 257 + 88; from the Society, at 1 Lowther Gardens, Prince Consort Road, London, S.W.7; 6*s*. or 7*s*. 6*d*. by post). It is arranged in the numerical order of the stands, totalling 131, which this year are to be housed in both the Old and New Halls of the Horticultural Society, thus giving much-welcome increased space for the display and demonstration of the exhibits. The exhibitors include, as formerly, government research establishments, universities, and scientific and technical publishers, in addition to about ninety-five manufacturers of scientific equipment. A brief description is given in the handbook of each particular item to be exhibited, in many cases also accompanied by an illustration, and a note is added to show whether the instrument or apparatus to be demonstrated is merely a prototype, is in production or can be made to order. The excellent indexes of both exhibitors and exhibits which preface the handbook will be found to be most helpful to users. To those who are unable to visit the exhibition, the handbook can be recommended as a comprehensive catalogue of modern physical apparatus and a quick reference book to the leading manufacturers. The advertisement section alone, consisting of eighty-eight pages, is in itself a most valuable collection of interesting information.

British Chemical Engineering

THE first number of *British Chemical Engineering* is attractive and readable (Drury House, Russell Street, London, W.C.2). There is always a place for commercial journals in engineering, which is commercial itself in essence. They will be read by engineers if they contain the news. The news is not solely a matter of research work, but of developing ideas, new emphasis, new invention and the plain story of what the other man is doing. The development of ideas in chemical engineering has shown a change since the War. The straight classification of techniques into unit operations has yielded to an insistence on fluid flow, heat and mass transfer as fundamental to them all. The strength of present design methods is shown in the first article on achievements at Windscale. These were made (and made better according to Sir Christopher Hinton) without benefit of pilot plant. This view is also put forward by Lincoln T. Work in the last article. The leader and editorial comments are well written and well informed. The criticism levelled at the lack of chemical engineering research in government stations is not founded on a careful study of the work going on, but on the annual report of the Department of Scientific and Industrial Research, which is condensed. Other articles are of a good standard and the features well planned. This is altogether a professional production and will need to maintain a level to justify a title which involves so much.

Nematologica: New Journal of Nematological Research

A NEW international quarterly journal of nematological research, *Nematologica*, has been founded through the initiative of Dutch workers, after informal discussion among some of the participants at the third symposium on plant nematology, held at Wageningen in July 1955. The editorial board consists of J. H. Schuurmans Stekhoven, J. W. Seinhorst, M. Oostenbrink, and P. A. van der Laan, of the Netherlands; they are assisted by advisory editors from fourteen countries, including the United States and the U.S.S.R., with F. G. W. Jones and B. G. Peters from Great Britain. The first issue (1, No. 1; 1956. Pp. 80+10 plates. Leyden: E. J. Brill; 28 florins per volume of four parts) contains about half the communications to the above symposium, and the second is to contain the remainder. The editors state that, in consequence, these two issues will not be representative of future issues, for the communications were all relatively short and most of them in the field of agricultural nematology. Although future issues are to be concerned primarily with this aspect, it is hoped that the journal will cover the field of nematology in general, "except for papers on medical and veterinary subjects", and will also include studies in "taxonomy, physiology, morphology, genetics, and other more fundamental research". The journal also incorporates the *Nematological News* of Dr. A. H. Meyl (Germany); in the first issue, two pages of small print are devoted to this very useful feature.

Geographical Trends in the Soviet Union

In the September issue of the Russian journal, *Nauka i Zhizn* (Science and Life), K. V. Zvorykkin and G. M. Ignat'ev emphasize the importance of a closer connexion between geographical exploration and agriculture, as exemplified by some recent surveys by the Geography Department of the University of Moscow. Both geology and geography, they write, must to-day subserve strictly practical and utilitarian ends, with perhaps less of the glamour and adventure that enlivened the exploits of old. The former must be used for seeking far and wide for new oilfields or promising formations, and the latter for exploring throughout the length and breadth of the vast Soviet territories for more farmland to meet the rapidly increasing needs of a growing population and rising standard of living. However, the surveys they describe did not go very far afield: they went no farther, indeed, than Ryazan, which is practically in the Central Russian or Moscow region, and is not so very distant south-east from the University itself. The expeditions were mainly intended as practice and experience in agricultural survey work for the students and others, more particularly on existing or potential collective farms and the domains of the tractor service stations usually associated with several of such farms. State farms, too, were included. The first expedition was mainly confined to Zaraisk, a district of the Ryazan Government, and the second was called the Ryazan Expedition, though it too was limited to a relatively few collective farms in the Sapozhkovsk locality. Both aimed at providing as much information as possible from the point of view of the potential farmlands, including detailed maps, soil science, climatology, contours and water supply, and also some indication of the measures needed to make the land suitable for cultivation and optimum use. Though students from many other departments in the University took part—physical and economic geographers, geophysicists and cartographers, soil geographers, biogeographers, etc.—it would seem that the services of economic botanists, entomologists, and even zoologists and scientific stock-breeders would be needed to make a complete and really informative study, and these are not mentioned (unless included under biogeographers). Zvorykin and Ignat'ev are firmly convinced that in conformity with the far-reaching and ambitious economic planning for Soviet industry and agriculture, as set forth in some detail at each succeeding plenary session of the Central Committee, geographers must considerably broaden their ideas; they must even extend the range and variety of their work beyond that of agricultural requirements to the industrial field generally, for example, in surveying suitable river sites for hydroelectric stations.

Forest Products Research during 1954

The annual report for 1954 of the Forest Products Research Laboratory, Princes Risborough (pp. 60+8 plates. London: H.M.S.O., 1955; 3*s*. 6*d*. net), shows that the scope and nature of the work undertaken have remained the same; the contact between the Laboratory and the trades and others interested in the utilization of timber and its products have been close; and the number of inquiries reaching the Laboratory is still on the increase. One significant change in the work has been a decrease in the emphasis on the testing and assessment of new Colonial timbers which has formed such an important and valuable part of the work of the Laboratory during past years, more time having been devoted to the examination of various species of home-grown timber in co-operation with the Forestry Commission. Now that the new plantations are reaching a size when thinnings can be made in them, the strength or degree of these thinnings in various species of crops is undergoing sylvicultural experiment. As the work proceeds, with the increase in age and size of the wood, the Laboratory will be able to give valuable assistance in testing the timber quality of the various species being used, the soils on which they are grown and various other locality factors, including the management applied. Tests of timber seasoning and important plywood experiments are under investigation. The Entomology Section reports the discovery of the house longicorn beetle in Surrey a few years ago. It is a menace to softwood structural timbers and is well known on the Continent of Europe. So far, in spite of careful investigation, it has only been found in a comparatively restricted area in Surrey. It is said to attack the hardwood oak in Great Britain. The death-watch beetle has been under study for some time in the Section.

Australian Earthworms

The longest earthworm in the world, *Megascolides australis*, is found in Gippsland, Australia, and grows up to eleven feet in length. Its habit of 'squirting' has been described by Elizabeth C. Pope (*Austral. Mus. Mag.*, 11, No. 12; December 1955). When disturbed, the worm squirts out a series of pairs of jets of fluid from a line of pores opening down each side of the body. The effect can be most spectacular, for these jets rise as high as eighteen inches or two feet into the air. Although there are reports that the fluid has a corrosive action, it is only slightly alkaline and contains some dissolved salts, body wastes like urea and some proteinous materials and cells. The fluid comes from the worm's body cavity and is squirted out by violent contractions of the body-wall which force the fluid out under great pressure through the pores. There is no record of the fluid having anything but a mildly irritating effect on the skin of human beings. The fluid is used for lining or lubricating the burrows of the worms. The article also refers to other 'squirter' earthworms.

Barley Mutants

T. Lawrence (*Canad. J. Bot.*, 33, 6, 515; 1955) has described the production of mutations by irradiating Montcalm barley in different ways. Five radiation sources were used for inducing mutations in barley, all treatments being given at a dosage of 10,000 r. equivalent. The radiation sources with their respective dose-rates in the region of the irradiated seeds were: a betatron (181·8 r./min.), an X-ray machine (201 r./min.), radium–beryllium (5·3 r./min.), and two cobalt-60 sources (4·5 r./min. and 75·75 r./min.). None of the radiation sources used was more effective than the X-ray treatment in producing mutations. The betatron and the high dose-rate treatments from cobalt-60 appear to be somewhat less effective than X-rays. More than thirty different mutant types were produced, including a number of vital mutants, such as stiff-strawed and early-maturing types. These appear promising as new varieties, but require further agronomic evaluation.

University of Birmingham: Appointments

Dr. N. A. Dudley, lecturer in engineering production in the University of Birmingham, has been appointed reader in engineering production and head of the Department of Engineering Production for a period of three years. The following have been appointed to lectureships in the University: T. K. Chaplin (civil engineering), Dr. T. B. Massalski (physical metallurgy), R. B. Hoole (mining) and Dr. J. N. Hawthorne (pharmacology). The following members of staff of the National Vegetable Research Station, Wellesbourne, have been appointed recognized lecturers in the University: D. W. Wright (attached to the Department of Zoology) and Dr. W. G. Keyworth (attached to the Department of Botany).

Royal Institution: Officers

The following have been elected officers of the Royal Institution: *President*, Lord Brabazon of Tara; *Treasurer*, Mr. W. E. Schall; *Secretary*, Mr. S. Robson; *Managers*, Dr. T. E. Allibone, Mr. E. R. Davies, Sir Alfred Egerton, Dr. A. G. Gaydon, Mrs. H. K. Hawkes, Brigadier H. E. Hopthrow, Mr. L. B. W. Jolley, Dr. H. Lowery, Mr. J. A. Oriel, Prof. H. J. Plenderleith, Dr. J. H. Schulman, Mr. P. H. Schwarzschild, Dr. R. Seligman, Dr. C. Keith Simpson and Prof. W. D. Wright; *Visitors*, Lieut.-Colonel S. J. M. Auld, Mr. F. G. Brown, Mr. R. C. Chirnside, Dr. F. H. Cotton, Mr. H. W. Cremer, Miss E. H. Jebens, Dame Kathleen Lonsdale, Mr. G. Parr, Mr. J. D. Peattie, Dr. R. Scott Russell, Miss Daphne Sidebottom, Dr. P. C. Spensley, Mr. W. R. Stevens, Mr. S. A. Stigant and Dr. D. T. A. Townend.

Institute of Petroleum: Officers

The following have been elected officers of the Institute of Petroleum for 1956–57: *President*, Rt. Hon. Lord Geddes; *Past-Presidents*, Lieut.-Colonel S. J. M. Auld, T. Dewhurst, Dr. A. E. Dunstan, E. A. Evans, Prof. F. H. Garner, H. S. Gibson and C. A. P. Southwell; *Vice-Presidents*, Dr. E. B. Evans, A. C. Hartley, E. LeQ. Herbert, R. B. Southall and E. J. Sturgess; *Honorary Treasurer*, G. H. Coxon; *Honorary Secretary*, C. Chilvers; *General Secretary*, D. A. Hough; *Editor*, George Sell; *New Member of Council*, M. E. Hubbard.

Annual Meeting of the Society of Chemical Industry

In addition to the lectures to be given at the seventy-fifth annual meeting of the Society of Chemical Industry during July 9–15 (see *Nature*, March 31, p. 609), a number of visits will be made to factories and research organizations in the London area. They include the Paint Research Station at Teddington, the National Institute for Medical Research, the Central Electricity Authority (Bankside Generating Station), Glaxo Laboratories, the Isle of Grain refinery of Shell-Mex and B.P., and the Atomic Energy Research Establishment at Harwell. The meeting begins with a reception on the Monday evening at Guildhall by the chairman, Sir Charles Dodds, and Lady Dodds, and the annual general meeting will take place the next day. The annual dinner will be held on the Wednesday at the Dorchester Hotel.

South-Eastern Union of Scientific Societies: Congress in Tunbridge Wells

The sixty-first congress of the South-Eastern Union of Scientific Societies will be held during May 24–27 in Tunbridge Wells, the town where the Union first met in 1896. The president-elect is Dr. W. E. Swinton, chief scientific officer of the British Museum (Natural History), whose address, "Nature and the Free Mind", will be given on May 25. In the various sections of the Union, addresses will be given by the following: *Archæology*, Major J. M. T. Burchell (the archæology of the Medway Estuary); *Botany*, Prof. C. T. Ingold (Gasteromycetes or Nature tries again); *Geology*, C. Fagg (swallow holes in the Mole Gap), and Prof. S. W. Wooldridge (geomorphology of the central Weald); and *Zoology*, Prof. H. R. Hewer (the importance of keeping field records). Further information can be obtained from the honorary local secretary, Mrs. H. Vernede, Carlton House, Carlton Road, Tunbridge Wells, Kent.

Tenth International Congress of Entomology, Montreal

The Tenth International Congress of Entomology will be held in Montreal during August 17–25, the meetings being at McGill University and the University of Montreal. The sections of the Congress have been arranged provisionally as follows: systematics, morphology and anatomy, physiology, behaviour, ecology, geographical distribution, genetics and biometrics, palæontology, arachnids and other land arthropods, agricultural entomology, forest entomology, medical and veterinary entomology, entomology of stored products, biological control, and apiculture. A visit to the Science Service Laboratories, Ottawa, and a number of short excursions will be made during the Congress, following which tours to a number of more distant laboratories and excursions for collecting will be arranged. Further information can be obtained from the secretary of the Congress, J. A. Downes, Division of Entomology, Science Service Building, Ottawa, Ontario.

Third International Congress on High-speed Photography

The third international congress on high-speed photography will be held in the Government Offices, Horse Guards Avenue, London, S.W.1, during September 10–15, and is being sponsored by the Department of Scientific and Industrial Research. The following main topics will be considered: flash sources for high-speed photography and high-speed cinematography; mechanical-optical cameras and drum cameras; high-speed shutters, and scanning and image dissection methods; and recent applications of these techniques in research, and particularly in the fields of industrial machine analysis, explosive studies (including atomic research), hydrodynamic and aerodynamic research, and medical and biological research. An exhibition of high-speed photographic and cinematographic equipment and associated instrument aids will be held concurrently with the congress, and admission to this exhibition will be free (tickets being obtainable by post from the congress secretariat). The membership fee for the congress is £6 10*s*. Further information can be obtained from the congress secretariat at the Department of Scientific and Industrial Research, Charles House, 5–11 Regent Street, London, S.W.1.

Announcements

Dr. R. F. Gordon, director of the Houghton Poultry Research Station, has been appointed adviser on poultry research to the Agricultural Research Council. The post of adviser is a part-time one, his function being to keep under review research in progress on poultry and to act as technical secretary to the Council's Committee on Poultry Research.

Mr. A. O Coinneáin, of the Department of Industry and Commerce, Republic of Ireland, has been appointed chairman of the Irish National Committee for Geodesy and Geophysics in succession to Mr. T. O Muireadhaigh.

Mr. Lennart Holm, of the Institute of Systematic Botany of the University of Upsala, has been awarded the 1956–57 Graduate Fellowship of the Mycological Society of America. Mr. Holm, a student of Dr. Nannfeldt, is studying the classification of the Ascoloculares. This is the first time the award has been made to a European student.

The National Physical Laboratory, Teddington, is holding an open day on May 25. Admission is by ticket only, and a limited number of invitations for the afternoon period 1.30–5.30 p.m. are available on application to the Director.

The second Symposium on Condensation Nuclei will be held in Basle and Locarno (Switzerland) during October 1–5, 1956. Those who wish to read papers should write before July 15 to Dr. M. Bider, Astronomisch–Meteorologische Anstalt der Universität, Binningen, Switzerland.

The British Society of Rheology is holding a symposium on "Rheological Research in the Textile Industry" during June 7–8 at the laboratories of the British Rayon Research Association, Manchester. Further information can be obtained from the Secretary, British Society of Rheology, 52 Tavistock Road, Edgware, Middlesex.

The eleventh symposium of the Society for Experimental Biology will be held in the University College of Wales, Aberystwyth, during September 10–14, the subject of the symposium being "The Biological Action of Growth Substances". Non-members of the Society may attend on payment of a registration fee of two guineas. Further information can be obtained from the honorary symposium secretary, Dr. J. F. Sutcliffe, 68 Half Moon Lane, London, S.E.24.

The twenty-first Cold Spring Harbor Symposium on Quantitative Biology will be held during June 4–12, the topic for discussion being "Genetic Mechanisms—Structure and Function". Genetic mechanisms will be considered on the chemical, genic, chromosomal, cellular and developmental levels. The Symposium is open to all on application to the Biological Laboratory, Cold Spring Harbor, New York, whence the full programme and further information can be obtained.

The German Geophysical Association and the German Meteorological Association will be holding a joint meeting in Hamburg during September 25–29. A number of topics of mutual interest will be discussed, and papers are invited (which, together with a summary, should be submitted before June 15). Further information can be obtained from the Deutsche Geophysikalische Gesellschaft, Rothenbaumchaussee 80, Hamburg 13, or the Meteorologische Gesellschaft in Hamburg, Bernhard-Nocht-Strasse 76, Hamburg 4.

A conference on "Heat Treatment Practice", organized by the Metallurgy (General) Division of the British Iron and Steel Research Association, will be held at Ashorne Hill, near Leamington Spa, during June 5–6. There will be three sessions on the following topics: distortion and cracking problems; heating for forging and treatment; and transformations. Application forms and further information can be obtained from the organizer and secretary, Mr. J. R. Powell, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

The title of the quarterly bulletin *Terminological and General Language Review* has been changed to *Reading and Listening Linguistically*, and although the bulletin remains essentially the same in its purpose, namely, the application of the linguistic approach when reading an article so as to pick out the essential features, greater emphasis will be given in the future to the needs of non-academic readers. The bulletin is produced by W. R. Dunlop, 57 Gordon Square, London, W.C.1, from whom further information can be obtained.

The American Physiological Society has given permission to the Johnson Reprint Corporation (125 East 23 Street, New York 10) to reproduce, by the photo-offset process, certain volumes of *Physiological Reviews* and the *American Journal of Physiology*, which are no longer available. The first sets of reprints (*Physiol. Rev.*, 19–29; 1939–49) are expected to be ready before the end of the year at approximately 15 dollars per paper-bound volume. Later, the Corporation hopes to reproduce the following: *Physiol. Rev.*, 31 (1951) and 34 (1954); *Amer. J. Physiol.*, 1–103 (1898–1933) and 114–116, 118–132, 140–145, 147, 152–159 (1935–49).

The Mond Nickel Fellowships Committee is offering up to five travelling fellowships, open to persons of British nationality with degree or similar qualifications, not necessarily in metallurgy, so that they can obtain additional training and experience in industrial establishments at home or abroad (in special circumstances, at a university) in order to make them more suitable for employment in technical and administrative positions in British metallurgical industries. The fellowships will be for one year and will be worth £900–1,200. The awards are seldom made to persons more than thirty-five years of age. Application forms, to be completed by June 1, and further information can be obtained from the Secretary, Mond Nickel Fellowships Committee, 4 Grosvenor Gardens, London, S.W.1.

DIET AND ANÆMIA

THE hundredth meeting of the Nutrition Society, held at the Medical College, London Hospital, on March 10, took the form of a symposium on "Diet and Anæmia", which some 118 members and guests attended. The chair was taken by Sir Stanley Davidson, who in a brief introduction referred to the improvement in the clinical picture which has been effected by better medical education and treatment based on much research, culminating in the discovery of vitamin B_{12}.

The morning session was devoted mainly to the causes of anæmia. The first paper, by Dr. G. R. Wadsworth and Prof. B. S. Platt (London School of Hygiene and Tropical Medicine), was entitled "Zymotic and Other Factors in the Development of Anæmia" and dealt especially with factors affecting the protein economy in its relation to the development of anæmia. About 6 gm. of globin from hæmoglobin is recycled daily, or about a tenth of the estimated total daily protein requirement. If the breakdown products of globin are not returned to the metabolic pool, anæmia may develop if there is deficient protein intake or lack of specific hæmatinic substances such as vitamin B_{12} or folic acid. However, the formation of hæmoglobin takes precedence over that of all other body proteins, even of serum protein; hence deficiency of hæmoglobin may not become evident for a long time, and then will be more readily detected by a fall in the total amount of hæmoglobin in the body rather than by a fall in hæmoglobin concentration in the blood, according to recent findings by Hallgren. Feeding experiments with glycine labelled with nitrogen-15 or with carbon-14 support the view that hæmoglobin may be partly derived from stroma protein and may be synthesized, while the maturing red cell is in circulation, from substances derived from the plasma. Severe anæmia may develop in infections (for example, meningitis) when iron therapy may be of value, in infestations (for example, malaria, hookworm) and following severe burns.

The second paper, by Prof. A. W. Woodruff (London School of Hygiene and Tropical Medicine), dealt with anæmia due to malnutrition in the tropics and mentioned the high maternal mortality-rates in Indian cities. Some nutritional megaloblastic anæmias may be due to deficiency of the Wills factor, which may be distinct from folic acid and vitamin B_{12}. Anæmia due to protein malnutrition may be macronormoblastic, with fibrosis of liver and fatty infiltration, the erythrocytes often being broader and thinner than normal. In the tropics, this type of anæmia can be more serious than megaloblastic and other nutritional anæmias.

The third paper, by Dr. P. B. B. Gatenby, of the Rotunda Hospital, Dublin, dealt with anæmia of pregnancy, which has been investigated there since the beginning of 1953. A special study in 1953 of four hundred cases of severe iron-deficiency anæmia (hæmoglobin less than 9 gm. per 100 ml.) showed half of them to have seldom or never eaten meat or other animal food such as eggs. Iron therapy corrects the anæmia and often prevents relapse to the iron-deficient state before the next pregnancy. In the absence of iron therapy, the incidence of the anæmia increases with the number of pregnancies and with the lowered dietary intakes of iron and vitamin C. In twenty-eight cases of megaloblastic anæmia in which a particular note was taken of the diet, twelve were eating very little meat or eggs, and another eight lacked protein foods, while the remaining eight had an apparently normal diet. Almost all the cases of iron-deficiency anæmia respond to folic acid and some to massive doses of vitamin B_{12}.

In the subsequent discussion, Dr. Lucy Wills expressed the opinion that macronormoblastic anæmia of pregnancy such as was encountered by Prof. Woodruff in Nigeria is an intermediate stage, developing later into megaloblastic anæmia. Prof. Woodruff in his reply suggested that this state of affairs may be due to a deficiency of vitamin B_{12} or of folic acid combined with a protein deficiency.

In the afternoon session, Dr. G. H. Spray (Nuffield Department of Clinical Medicine, Oxford) read a paper on "The Role of Pteroyl Glutamic Acid and Related Compounds in Macrocytic Anæmia". The history of the problem since Wills's work in 1931 was first briefly reviewed. The limited effectiveness of yeast extracts such as 'Marmite' in the treatment of pernicious anæmia may be due to their content of folic acid, although the possible existence of an unidentified 'Wills factor' is not yet entirely ruled out. A normal serum vitamin B_{12} in megaloblastic anæmia is generally taken to indicate a deficiency of folic acid, for which there is no simple test yet available. A hæmopoietic response to folic acid is usually assumed to indicate a disturbance in the metabolism of this factor, which may be due to dietary deficiency (for example, nutritional macrocytic anæmia in India and Africa), defective absorption (in tropical sprue and idiopathic steatorrhœa) or excessive demands, as in pernicious anæmia of pregnancy. In India, Africa and the southern United States, nutritional macrocytic anæmia occurs which is associated with low intakes of fresh fruit and green vegetables and is corrected by oral administration of folic acid. If there is also a very low intake of animal protein, vitamin B_{12} deficiency may be encountered. Anæmia in cases of epilepsy may be due to the use of phenytoin, a possible antagonist to folic acid.

Vilter and his colleagues suggest that folic acid and vitamin B_{12} take part in reactions leading to the synthesis of the nucleoproteins of blood cells from simple precursors. In the absence of vitamin B_{12} there is an excessive demand for folic acid, which keeps the reactions going by 'mass action', and it may eventually become deficient. Large doses of folic acid increase blood formation, using up the remaining small stores of vitamin B_{12} and causing exacerbation of the nervous degeneration. In patients with pernicious anæmia, there may be eventually hæmatological relapse. This useful working hypothesis does not explain completely the role of folic acid in blood formation, its utilization from the diet, its storage and excretion, and the question as to the utilization of folic acid synthesized by intestinal bacteria still remains unanswered.

The second paper in the afternoon session was by Dr. J. R. Evans (Nuffield Department of Clinical Medicine, Oxford) and dealt with the absorption of vitamin B_{12} in the megaloblastic anæmias. Vitamin B_{12} labelled with cobalt-60 was used, and the radioactivity of the fæces was measured after an oral dose of 0·5 μgm., the assumption being made that all radioactivity not recovered in the fæces had been absorbed. In forty-four observations on thirty-five control subjects, the radioactivity in the fæces ranged from 9 to 47 per cent and averaged 27·3 ± 1·6 per ent of that present in the oral dose. In twenty-four pernicious anæmia patients, the corresponding verage percentage was 92·3 ± 1·3. When these patients were given intrinsic factor, most of the esults were within the limits observed in normal subjects. Achylia and atrophy of the gastric mucosa upported these findings in each of nineteen of the atients who were studied. Sterilization of the bowel with chlortetracycline did not increase the uptake of abelled vitamin B_{12} in a patient with untreated ernicious anæmia. Studies on megaloblastic anæmia ollowing gastric surgery showed that, after total astrectomy, little or no labelled vitamin B_{12} is bsorbed unless intrinsic factor is given with it. In ve patients with partial gastrectomy, failure of bsorption was corrected by intrinsic factor, while in nother nine patients in whom no megaloblastic næmia developed after removal of the distal half of he stomach, there was no permanent impairment of itamin B_{12} absorption. In seven patients with liopathic steatorrhœa and megaloblastic anæmia, bsorption was normal in one young patient, slightly npaired in another and negligible in the remaining ve. Intrinsic factor seldom caused improvement, ven when given in very large doses. In another four atients with idiopathic steatorrhœa, but no megaloblastic anæmia, absorption was normal in three, nd only slightly reduced in the fourth. Absorption as unaffected in megaloblastic anæmia of pregnancy r the puerperium and in megaloblastic anæmia ssociated with epilepsy.

The final paper, by Dr. F. Wokes (Ovaltine esearch Laboratories, King's Langley), described næmia associated with dietary deficiency of vitamin $_{12}$ encountered in a group of about a hundred and fty persons termed 'vegans' who consume no animal od whatever. There was no megaloblastic or acrocytic anæmia, but in rather less than half the ıbjects there were low serum B_{12} levels (less than 0 μμgm./ml.) accompanied by neurological manistations ranging from slight paræsthesia to subacute mbined degeneration of the cord. The wide riation in response was probably not due to riations in dietary intake of the vitamin, which as not found in significant amounts in the foods nsumed by the 'vegans'. It was thought to be ore likely to be caused by differences in the degree intestinal synthesis of the vitamin.

Study of the 'vegan' diet showed its vitamin ntent to be satisfactory, apart from B_{12} and ssibly also D. The average protein intake was ther low (9–11 per cent on the calorie basis), and e large amounts of pulses consumed tended to lead a deficiency of methionine, which would be gravated by the deficiency of vitamin B_{12}. This, gether with the unusually high intakes of folic acid m green vegetables, may have been responsible the neurological manifestations.

The part played by vitamin B_{12} in the *de novo* nthesis of labile methyl groups to convert homosteine to methionine, and also in the reduction of sulphide to sulphydryl groups, has led to a study 'vegans' and non-'vegans' of the metabolism of iocyanate, the sulphur-containing detoxification oduct of cyanide, in the metabolism of which amin B_{12} in the form of hydroxo- or aquocobalmin appears to be implicated. A sulphur transfer cycle was described for synthesis of essential sulphur-containing metabolites which might include the methionine deficient in 'vegan' diets. Lack of vitamin B_{12} might also, by inhibition of a sulphydryl system, lead to abnormal metabolism of tryptophan and tyrosine, with accumulation of toxic products, which might be responsible for the neurological manifestations.

In the subsequent discussion, Dr. C. C. Ungley described scotomata occurring in one of the 'vegans', which were cured by prolonged administration of vitamin B_{12}.

VEGETABLE TANNINS

SYMPOSIUM IN CAMBRIDGE

THE Society of Leather Trades' Chemists held a symposium on "Vegetable Tannins" during April 12–13 in the Chemistry Department, University of Cambridge, at which more than a hundred members and guests participated.

After the symposium had been opened by the president of the Society, Dr. R. G. Mitton (British Leather Manufacturers' Research Association), the chairman, Prof. R. D. Haworth (Chemistry Department, University of Sheffield), briefly referred to Emil Fischer's outstanding contribution to the chemistry of the gallotannins and mentioned how the early optimistic attempts of the 1920's to bring order to the untidy field of tannin chemistry was not realized. The reason for this is that those physical methods, which are now used for the isolation of single substances, were unknown. As a result of recent work, much of which, said Prof. Haworth, has been carried out by those present at the symposium, order and interest have been restored. Considerable academic and technical research is now in progress, and we have learned much concerning the units from which the complex tannins are composed.

In an introductory paper, on the scope of vegetable tannin chemistry, Dr T. White (Forestal Central Laboratories) treated historically the chemistry of the tannin and related polyphenol constituents of the principal vegetable tannin extracts. He dealt with the previously proposed classification of tannin extracts, defined a tannin (as opposed to a polyphenol) and directed attention to tannin action. New work on the degradation of the major constituent of commercial gallotannin was outlined. The preliminary results can be interpreted in terms of a trisaccharide formula which is reminiscent of the tetrasaccharide formula proposed this year for sumach gallotannin by Grassmann and co-workers. Dr. White stressed that the condensed tannins cannot now be considered as a single class of compound. His paper included a review of the physical chemistry of gross tannin extracts, and a provocative account of the physiological function of tannins in the intact plant, notably as inactivating agents for vector-transmitted virus proteins.

Mr. H. G. C. King (also of the Forestal Central Laboratories) and Dr. White then gave a paper on quantitative determination of specific nuclei and components of vegetable tannin extracts. In the same way that paper chromatograms may be used for the separation of tannin constituents, they may also form the basis for the estimation of these substances, when used in conjunction with specific reagents and reflectance spectrophotometry. Examples of catechol, monosaccharide, phloroglucinol, pyrogallol and resorcinol estimations were included.

In a paper on gallotannins and ellagitannins, Prof. D. Burton and Dr. H. E. Nursten (University of Leeds) outlined the work of the Leather Industries Department at Leeds under the successive administration of Profs. Atkin and Burton, both of whom had applied electrometric titration methods to gross tannin extracts and their dialysates, plant acids and their salts being found in the dialysate. By means of cation-exchangers, the salt content was estimated before and after dialysis. Application of these methods to the types of extract under consideration has afforded analyses of use to the industry.

Prof. O. Th. Schmidt (Chemical Institute of the University of Heidelberg) then gave a paper on the constitution of chebulinic acid. A Diels–Alder adduct of dimethyl fumarate and 1-acetoxybutadiene was formed, and the configuration of the separate racemates was unambiguously determined. Treatment of the *trans-trans*-tetrahydrophthalic acid dimethyl ester with ozone and hydrogen peroxide successively gave a cleavage product, the antipodes of which were resolved with brucine. One antipode was identical with the butanol tetracarboxylic acid lactone, derived from chebulic acid. Hence, both these substances have the racemoido-racemoido-configuration. Addition of the elements of water to chebulinic acid gave *neo*chebulinic acid, which afforded chebulic acid and a trigalloylglucose on hydrolysis. The latter proved to be identical with 1β : 3 : 6-trigalloyl-D-glucose, which was synthesized from triacetyl-L-glucosan. Application of the new results suggests a constitutional formula for chebulinic acid.

In his exploratory study of the polyphenols and polyphenolase of tobacco, Mr. W. W. Reid (Research Department, Carreras, Ltd.) fractionated tobacco extracts by lead acetate precipitation and solvent extraction. These fractions were further subdivided as band chromatograms on thick paper, and homogeneous fractions were estimated by modern scanning techniques. Cellulose columns were also employed, and the enzymic oxidation of the resulting polyphenols by tobacco polyphenolase was studied.

In a contribution on paper chromatography as an aid to the elucidation of the structure of polyphenols occurring in tea, Dr. E. A. H. Roberts (Indian Tea Association Chemical Laboratory) exemplified the technique by the separation of (+)- and (−)-catechin and of *cis*- and *trans*-cinnamic acids. Accordingly, (+)-catechin, (−)-*epi*catechin, (+)-gallocatechin, (−)-*epi*gallocatechin, and *cis*- and *trans*-chlorogenic and *neo*chlorogenic acids were identified, theogallin was shown to be a galloyl ester of quinic acid, and chromatographic evidence for the occurrence of both *p*-coumarylquinic acids and myricetin glycosides was advanced. The possibility of the production of benztropolones in tea fermentation was tentatively considered.

Dr. D. E. Hathway (British Leather Manufacturers' Research Association), in a communication on some approaches to aromatic biosynthesis leading to polyphenols and tannins, described the separation and identification of ellagic acid in plant extracts, and the separation of a plant acid fraction from myrobalans by means of ion-exchange chromatography. Related *cyclo*hexanecarboxylic acids were identified by paper chromatography, and they were separated by extended ion-exchange methods. The chromatogram of the polyphenols and tannins of myrobalan was elucidated. On account of Davis's microbia studies, and the presence of *cyclo*hexanecarboxyli acids concomitant with simple polyphenols an tannins in myrobalans, Hathway suggested that the may also be precursors of aromatic amino-acid polyphenols and tannins in the plant. The occurrenc of *cyclo*hexanecarboxylic acids in other plants wa mentioned, and the question of the ubiquity shikimic acid was raised. The use of radioactiv tracers in lignin biosynthesis was cited, and th emergence of C_7—C_9 plant compounds, includin gallic acid, from the *cyclo*hexanecarboxylic aci sequence was discussed.

On the second day the conference was continue under the chairmanship of Dr. F. E. King (Researc Department, British Celanese, Ltd.). In their revie of the leuco-anthocyanins, Drs. T. Swain and E. Bate-Smith (Low Temperature Research Statio Cambridge) have divided these substances into category requiring oxygen for the transformatio into anthocyanidin, and a category which does n require it. Little is known of the chemical structure many of these substances. King and Bottomley (195 isolated a leuco-anthocyanin, however, which the proved had a flavan-3 : 4-diol structure (7 : 8 : 3′ : 4 tetrahydroxyflavan-3 : 4-diol), the tetramethyl eth of which was afterwards synthesized by King an Clark-Lewis. Meanwhile, Swain had synthesized t 5 : 7 : 3′ : 4′-isomer by hydride reduction of taxifoli This new leuco-anthocyanin does not occur in Natur it being different from that in apple and cacao. Tw decades earlier, Robinson and co-workers provid considerable evidence for the structure of cyan maclurin and peltogynol, neither of which belongs the flavan-3 : 4-diol type. Leuco-anthocyanins a sometimes mobile on paper chromatograms, and th is a behaviour consistent with comparatively simp structures. A stationary class may be due chemically unidentified polymers.

Mr. W. E. Hillis (Division of Forest Produc Commonwealth Scientific and Industrial Resear Organization, Australia), in a communication leuco-anthocyanins as the possible precursors tannins, showed that the leuco-anthocyanin conte of vegetable tannin materials follows the intensity red colour imparted to leather. In regions of acti growth, such as the leaf tips and cambium duri spring, there is a relatively high accumulation leuco-anthocyanins. Mr. Hillis presented eviden that in eucalypts these substances originate in t leaves and move down the phloem across the ca bium into the wood. Leuco-anthocyanins may transformed into 'tannins' at the sapwood–heartwo boundary.

Dr. W. Mayer (Chemical Institute of the Univers of Heidelberg), in a paper on catechins from the ba of oak and sweet chestnut, described the isolation (+)-catechin and (+)-gallocatechin from these pla tissues. (+)-Gallocatechin proved identical w Oshima's casuarin. Reduction of the pentamet ether with sodium and alcohol invoked desmethox ation, and the resulting diphenylpropane was a obtained from pentamethyl (−)-*epi*gallocatechin a was synthesized via the chalcone. The simi desmethoxylation of O-trimethylpyrogallol w encountered by Kostanecki.

In a communication on the occurrence and pr erties of dihydroflavonols (4-oxocatechins), Dr. J. Gowan, Mrs. E. M. Philbin and Prof. T. S. Whee (Chemistry Department, University College, Dubl reviewed the occurrence of the eight dihydroflavonols in the plant kingdom: dihydro-kæmpferol and -myricetin occur most frequently. Dihydroflavonols have been synthesized by six methods: oxidation of 2′-hydroxychalcones and flavanones; bromination of flavanone, followed by nucleophilic replacement of halogen; ring-closure of 2′-hydroxy-α-methoxychalcones; treatment of 2′-acetoxychalcone dibromides with silver acetate or alkali; dithionite reduction of flavonols; and reaction of aromatic aldehydes with 2-hydroxyphenacyl chlorides. Under the influence of alkali, dihydroflavonol disproportionates into the flavonol and flavanone, or affords the corresponding 2-benzyl-2-hydroxycoumarân-3-one.

Dr. W. B. Whalley (Organic Chemistry Department, University of Liverpool), discussing the stereochemistry of the chromans and related compounds, dealt with a stimulating application of conformational analysis. In common with King, Dr. Whalley agrees with the assignment to catechin and *epi*catechin of *trans*- and *cis*-structures, respectively, but he produced evidence in favour of fresh conformations with 3(*a*)-hydroxyl groups for both substances. Conformational analysis has been extended to the 3-hydroxyflavanones, 2-hydroxy*iso*flavanones and flavan-3 : 4-diols, and it is evident that Dr. Whalley will elucidate the conformation of the complicated O-ring heterocyclics by application of stereo-specific reactions.

The Society will publish the symposium lectures and discussions in book form, and this should interest all those whose work brings them into contact with polyphenols, tannins and vegetable tannin materials.

EAST AFRICAN INDUSTRIAL RESEARCH ORGANIZATION

REPORT FOR 1954–55

The East African Industrial Research Organization, which incorporates the East African Industrial Research Board, came into existence on April 1, 1955, and its first annual report* is a progress report covering the period January 1, 1954–June 30, 1955. The new Organization absorbs the staff of the previous Board, and provision is made for a 60 per cent increase during the next two years. The British Government is contributing, from Colonial Development and Welfare Funds, 75 per cent of the apital expenditure for offices and laboratories and housing, and half the recurrent expenditure during the next two years. The Organization will be responsible to a board, on which the East African Government and the East African High Commission are represented.

The present report summarizes the work in the production of hecogenin from sisal waste, the plant or which has operated successfully since it was fficially opened in June 1954. A preliminary report as been issued on the investigation of coffee processing which indicates that there are three stages in rying fermented coffee and that it is desirable to ry-wash the fermented coffee initially as quickly as possible, without using too high a temperature. When the coffee is dry enough to be safe from eterioration, the remaining process may be a slower removal of moisture in a conditioning bin. Work with dual-fuel engines, using oil and indigenous wood, has shown that producer gas can replace diesel oil in a diesel engine and is utilized as efficiently thermally as the oil. Satisfactory ignition of the gas–air mixture can be achieved with a low proportion of the full-load consumption of oil; at least 70 per cent of the full-load rating of a coupled diesel engine and alternator can be carried on gas, while the governor retains full control of speed, and existing engines can be modified economically on the site.

Chemical engineering research has been concerned with the utilization of natural steam, the production of salt and lime burning; in ceramics a refractory grog has been produced by calcining fine kyanite, bonded into pellets with molasses in a rotary kiln, and also a porous grog by grinding raw kyanite with charcoal, pelleting with molasses and calcining in the laboratory at 1650° C. Other work has been concerned with the production of phosphatic fertilizers and the pelletizing of cetyl alcohol for use in retarding the evaporation of water from dams. For this latter purpose, following work by A. F. C. Cole, who died during the period, apparatus has been devised by which an output of 20 lb. a day has been achieved. The apparatus is described and illustrated in the report.

CURRENTS THROUGH THE STRAITS OF DOVER

Nearly a hundred and twenty-five years ago Faraday predicted that electrical potential differences would be set up in sea water, a conducting fluid, by its motion in the Earth's magnetic field. His predictions were verified by measurement of voltages induced on submarine cables. During recent years, oceanographers have begun to use measurements of the voltage differences in sea water as a useful method of studying water transport. In a recent paper (*Phil. Trans. Roy. Soc.*, A, **248**, 953; 1956) K. F. Bowden has demonstrated the value of the method in his study of the flow through the Straits of Dover. He has taken as his raw material fifteen months of continuous observations of the voltage fluctuations induced on a cable crossing the Straits of Dover, together with four months of similar observations on a cable crossing the southwestern portion of the North Sea. Regular voltage fluctuations, about one volt in amplitude, produced by the tidal currents are a dominant feature of his records. These fluctuations, while serving a useful purpose for calibrating the voltage in terms of the mean flow through the Straits, have to be eliminated to study the more interesting residual currents. The calibration, which depends on the conductivity of the sea bed as well as the sea water, is done empirically. Shorter-period fluctuations produced by magnetic disturbances are eliminated by filters in the measuring equipment and by smoothing of the graphical records.

Prof. Bowden shows that the residual currents, which sometimes run with speeds as high as one and a half knots in either direction, are highly correlated with the local winds and the slope of the sea surface along the Straits. The correlation is also high with the wind system over the southern part of the North Sea and the English Channel, indicating that the surface slope along the Straits is largely a consequence of the regional wind system, though influenced as well by other factors. Prof. Bowden's measurements enabled him to make estimates of the coefficients of wind stress and of bottom friction. These estimates, though somewhat high, agree in magnitude with other independent estimates and strengthen the probability that further development of the dynamics of the air–sea interactions can be made through similar studies. Such studies are at present being made of the Gulf Stream through the Florida Straits and of currents in the Cook Straits of New Zealand, and others are being planned.

Prof. Bowden was perhaps fortunate in studying a region that has been extensively surveyed in the past and he had access to detailed meteorological and tidal information in carrying out his analysis. The method he has employed has emerged as a powerful supplement to the usual techniques of oceanographic survey and is, at present, the only practical way in which large-scale currents can be continuously monitored. N. P. FOFONOFF

AMPHITHALLISM IN FUNGI

By M. EILEEN KENNEDY and PROF. J. H. BURNETT

University of St. Andrews

IT has generally been found that the mating systems of fungi are very constant features and that if, for example, a species is heterothallic, it regularly produces spores which are homocaryotic in respect of mating type. However, exceptional fungi are known which produce spores both homocaryotic and heterocaryotic for mating-type factors on the same fruit body. Lange[1] introduced the term 'amphithallism' to describe this condition in species of *Coprinus*.

Recently we have investigated an amphithallic condition in some strains of bipolar gasteromycetes of the *Nidularia denudata* 'complex', and it is now evident that confusion has arisen in the application of Lange's term. This is because, first, different mechanisms give rise to the condition and, secondly, because the term has been applied to quite different phenomena.

At least four mechanisms are known which can result in the production of spores both homocaryotic and heterocaryotic for mating-type by a single fruit body, namely:

(1) In certain Basidiomycetes with four-spored basidia, an additional mitosis after meiosis results in the occurrence of eight-nucleate basidia. Two nuclei migrate into each basidiospore and they may carry the same or different mating-type factors, that is, the basidiospores will be homocaryotic or heterocaryotic for mating type, respectively. Unequivocal cytological and breeding evidence for this situation has been obtained in strains of *Nidularia denudata* by one of us (M. E. K.), details of which will be published elsewhere. Circumstantial evidence for a similar mechanism is available in *Omphalia flavida*[2], *Coprinus plagioporus* and *C. subpurpureus*[1].

(2) In certain Basidiomycetes with two-spored basidia, meiosis occurs in the basidium and two nuclei migrate into each basidiospore. Single basidiospore isolates usually germinate to give a mycelium bearing clamp-connexions. Exceptions have been recorded in *Coprinus sassii* (= *C. ephemerus* f. *bisporus*)[1,3], *Galera tenera* f. *bispora*[3], *Aleurodiscus canadensis*[4] and *Mycena rubromarginata*[5]. In these fungi some single-spore isolates failed to form clamp connexions, and appropriate matings demonstrated that such isolates, of the same species, carried complementary mating-type factors, that is, the basidiospores from which these isolates originated were homocaryotic for mating-type factors. Recently, Terra[6] has demonstrated that this interpretation is correct in *Stropharia umbonatescens* and has also demonstrated, by mechanical separation, the heterocaryotic nature in respect of mating type of the rest of the basidiospore isolates. It is not known at present why basidiospores of such fungi are normally heterocaryotic in this respect, although an association between nuclei of complementary mating type during migration into the spore has been suggested[3].

Basidiomycetes have been described which, in addition to two- and four-spored basidia, possess a variable but usually small number of basidia which bear three, five or more spores. It has been suggested[7,8] that unequal distribution of the four nuclei derived from meiosis to these basidiospores would result in spores homo- and hetero-caryotic in respect of mating type. No acceptable experimental evidence has been presented, as yet, in support of this claim.

(3) Most Ascomycetes regularly produce eight, initially uninucleate, ascospores; but occasionally some of them are replaced by 'giant' binucleate spores, some of which may be heterocaryotic for mating-type factors, for example, *Neurospora crassa*[9]. In other Ascomycetes four, initially binucleate, spores, each heterocaryotic for mating type, are formed regularly in each ascus. But in these fungi uninucleate ascospores, which are necessarily homocaryotic for mating-type, are formed exceptionally with variable frequencies, for example, in *Neurospora tetrasperma*[10], *Podospora anserina*[11]. The mechanism common to both these exceptional conditions is the irregular delimitation of the cytoplasm at spore formation, but the causes of such irregularities have not been fully investigated. A similar kind of irregularity is presumably responsible for the occasional heterocaryotic meiospores produced by the Phycomycete, *Phycomyces blakesleeanus*[12].

(4) Heterocaryosis for mating-type factors in the ascospores of the four-spored Ascomycetes such as *N. tetrasperma* is a consequence, not only of the mode of spore delimitation, but also of the orientation o the spindles during nuclear divisions in the ascus and the time of segregation of the mating-type factors during meiosis[13]. However, the occurrence of asc with initially binucleate ascospores, which are homocaryotic for mating type, has been reported[14,15]. In *N. tetrasperma* it has been suggested[16] that this may come about as a result of irregularities in spindle orientation; but a different mechanism, the intervention of crossing-over between the mating-typ locus and the centromere, which alters the spatial segregation pattern of the mating-type factors in the ascus, has been described[15] for *P. anserina*. Completely acceptable cytological and genetical evidenc for these hypotheses is not available.

Amphithallism can be applied to the results of th four types of behaviour described, since they all lead to the production of spores, homocaryotic and heterocaryotic for mating type, by a single fru body. But amphithallism will affect the matin systems of different fungi in quite different ways For example, in an outbreeding form such as *Coprinus subpurpureus*, amphithallism restricts the degree o potential outbreeding, but in an inbreeding fungu such as *Neurospora tetrasperma* it will introduce a measure of potential outbreeding.

The other point to which we direct attention is the suggested application by Olive[17] of amphithallism to an altogether different mode of behaviour. He has shown that single-ascospore isolates of *Sordaria fimicola* will produce fertile perithecia in culture, but if such isolates are grown in pairs, fertile perithecia are formed preferentially in the zone of contact between them. He suggests that the definition of amphithallism be extended to include this condition, which he describes as the tendency in a homothallic organism towards heterothallism. Such usage seems to us to be a misapplication of the term. Olive's situation is reminiscent of that described as "relative heterothallism" in *Aspergillus nidulans*[18], and the mechanisms responsible for these phenomena are not yet understood. But the causes and consequences of these phenomena must be entirely different from those responsible for the amphithallic condition as described earlier. [Feb. 4

EFFECT OF SOLUTE CONCENTRATION IN THE IRRADIATION OF AQUEOUS SOLUTIONS BY IONIZING RADIATIONS

By Drs. G. R. A. JOHNSON, G. SCHOLES and J. WEISS
King's College (University of Durham), Newcastle upon Tyne

DURING recent years, considerable attention has been paid to the chemical action of ionizing radiations on aqueous solutions, largely due to the possible significance from a radiobiological point of view. Most of the work hitherto reported in the literature has been concerned with very dilute solutions; but it is clear that, with regard to the elucidation of the reaction mechanisms as well as to the biological aspects, the behaviour of more concentrated solutions and altogether a much wider range of concentrations should be considered.

For dilute aqueous solutions, it is generally accepted that the chemical action of ionizing radiations on the olute is an indirect one, that is, via the free radicals OH and H) produced from the water[1]. On this basis, the chemical yield should be independent of concentration of solute over a fairly wide range, provided that sufficient solute is present to utilize all the available radicals produced from the solvent. It has been usually supposed that this, in fact, holds in all cases. With organic solutes, however, no clear xperimental evidence has been presented to prove uch a generalization.

In the course of some recent work on the mechanism f the chemical action of X-rays on several organic ompounds in dilute aqueous solutions, detailed tudies have been made of the effects of concentration of solute on the yields of radiation products. It has een found that in none of the cases so far investiated does the yield actually become independent of the solute concentration up to concentrations of bout 1 *M*. Fig. 1 shows the dependence of the nitial yields of acetaldehyde from aqueous ethanol solutions[2] and of pyruvic acid from lactic acid olutions, as a function of solute concentration; radiations were carried out in the presence of dissolved oxygen, at room temperature. These experinents show that within the range 10^{-5}–$1\cdot0$ *M*, the ield of the product never becomes independent of the solute concentration. The relative increase in oxidation yield is greatest in the lower region, that is, up to 10^{-3} *M*. However, at higher concentrations the yield still continues to increase and, in these systems, can eventually attain values which are considerably greater than the maximum that could arise from the yield of hydroxyl radicals resulting from the decomposition of water by the radiation, normally supposed to correspond to $G \simeq 3\cdot0$–$3\cdot5$ (molecules/100 eV.). Over the concentration-range considered here, 'direct effects', that is, changes due to the absorption of the radiation energy by the solute, even at the highest concentration employed, cannot amount to more than about 10 per cent.

In several other reactions induced by radiation in aqueous systems, for example, the formation of

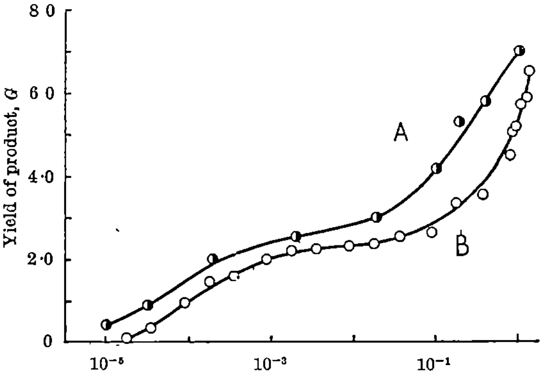

Fig. 1. Irradiation of aqueous solutions with X-rays (200 kV) in the presence of oxygen (1 atm.). pH = 1·2. Dose-rate = 2×10^{17} eV./ml./min. [$G(Fe^{3+}) = 15\cdot5$]
Dependence of the initial yields on the solute concentration. Curve *A*: pyruvic acid from lactic acid solutions; curve *B*: acetaldehyde from ethanol solutions

ammonia from α-alanine[3], of inorganic phosphate from the α- and β-glycerophosphates (Taylor, Scholes and Weiss, unpublished results) and from ethyl phosphate (Wheeler, Scholes and Weiss, unpublished results) and of acetaldehyde from ethylamine[2], it has been found that, over the range of solute concentrations studied, the yield of the product does not attain a constant value. All these experiments were carried out with X-rays (200 kV.) in the presence of dissolved oxygen. Some preliminary experiments, using cobalt-60 γ-rays, which have been carried out with the ethanol and lactic acid systems, have shown that the dependence of the yield on solute concentration is essentially similar to that observed with X-rays. Although in a given system the pH of the solution is sometimes a determining factor for the yield of the products, it does not, in general, appear to influence the overall dependence of yield on concentration.

A few cases have previously been reported in which the effects of solute concentration have been studied. It has been emphasized that there is a marked dependence on concentration of the yield of ammonia from glycine[4]; reference may also be made to the irradiation, with γ-rays, of solutions of formic acid[5] and of ethanol[6], where somewhat similar effects have been noted. It should be pointed out that in the early experiments of Fricke *et al.*[7], Kinsey[8], and Stenström and Lohmann[9], the yield of the product did not become independent of concentration over the range investigated.

Hydrogen peroxide is produced in all these solutions irradiated in the presence of oxygen, and the yield of this has been determined, in several systems, as a function of solute concentration. Some of the results obtained are recorded in Fig. 2. The rather striking fact emerges that the initial yield of hydrogen peroxide ($G(H_2O_2)$), in contrast to that of the organic product, is, in these cases, more or less independent of solute concentration over a relatively wide range; the value of $G(H_2O_2)$, however, varies according to the solute and must, therefore, be related to the mechanism of the oxidation processes involved. It is of some interest to note that in all the cases examined (cf. Fig. 2) the yield of hydrogen peroxide becomes practically independent of solute concentration when the latter exceeds about 10^{-3} M, that is, the concentration at which the rate of increase of the yield of the organic product changes markedly.

It is difficult to reconcile these observations with some of the simple views on the action of ionizing radiations in aqueous systems. The observed increase in the yield of organic product with increasing concentration of solute could possibly be explained, for example, by (*a*) reactions of the solute with hydrogen atoms when the concentration of the former is sufficiently high to compete with oxygen in the reaction $H + O_2 \rightarrow HO_2$; (*b*) electronic excitation of the solute molecules by the slow electrons produced by the ionizing radiations[10]; (*c*) further reactions of the solute with those active species (for example, free radicals) which may only become available at higher concentrations of solute. (It should be borne in mind that we have no independent knowledge of the extent of the primary decomposition of the water into free radicals, and there could be, in the more dilute solutions, an appreciable amount of recombination or deactivation of the active species.)

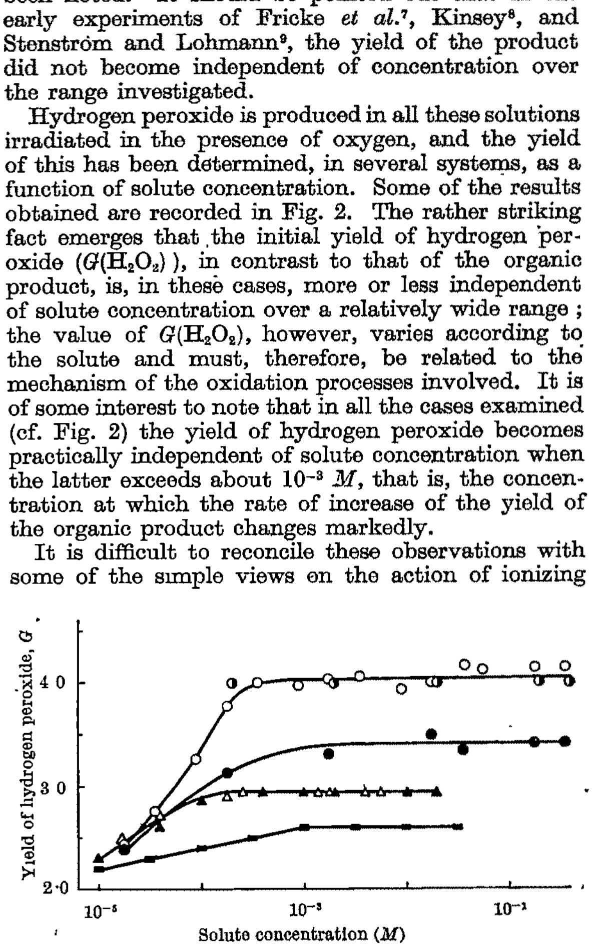

Fig. 2. Dependence of the initial yields of hydrogen peroxide on the solute concentration in different aqueous solutions irradiated with X-rays (200 kV.) in the presence of oxygen (1 atm.). Dose-rate = 2 × 10^{17} eV./ml /min. [$G(Fe^{3+})$ = 15 5]
○, Ethanol, pH = 1 2; ●, ethanol, pH = 5·5; ◑, lactic acid, pH = 1 2; ▲, α-glycerophosphate, pH = 1·2; △, β-glycerophosphate, pH = 1·2; ■, monoethyl phosphate, pH = 1·5

The dependence of the overall yield on the concentration of the solute ([c]) should be, in each of the cases discussed above, given to a first approximation, by an expression of the type:

$$\text{Yield} \simeq \frac{k_1 [c]}{k_2 + k_3 [c]}$$

where, in general, k_1, k_2, k_3 are functions of the various parameters such as the initial local concentration of the free radicals in the tracks of the ionizing particles, the concentration of molecular oxygen, etc.; the experimental results (cf. Fig. 1) do, in fact, appear to conform with such an expression. (It should be pointed out also that the nature of the yield-concentration plots does not support the occurrence of chain reactions in the systems under consideration.)

It is clear, from the above remarks, that in studies o the effects of ionizing radiations on organic compounds in aqueous systems, much more attention should be paid to the influence of concentration of solute , selection of any arbitrary concentration for the elucidation of the reaction mechanism may lead to erroneous conclusions. In particular, caution must be exercised in deriving values for the yields o primary radicals from the results obtained in any system at any one concentration of solute. Never theless, the study of aqueous systems of organic compounds, rather than of some simple inorganic systems, appears to be capable of yielding more complete information about the various primary processes following absorption of radiation, since i is possible that some important features may not b revealed in simple inorganic systems where the sam product is often formed via different routes.

Some of the experiments reported here were carrie out by Mrs. Freda Hope, to whom our thanks ar due. We wish to acknowledge, with thanks, th financial assistance of the North of England Counc of the British Empire Cancer Campaign and of th Rockefeller Foundation. [Feb. 27

Structure of Azulene

Previous work on the crystal structure of azulene[1] was shown that the apparent space group is $P2_1/a$ C^5_{2h}) with two molecules in the unit cell. This implies centrosymmetric molecule, which is in conflict with he chemical evidence. The two most likely explanaons of this discrepancy are : (*a*) that the implied centre of symmetry is only statistically true, and is ue to rotating molecules or a disordered structure ; or (*b*) that the absent spectra leading to the deduction of the space group $P2_1/a$ are accidental, and that the rue space group is really of lower symmetry. Günthard[2] has discussed these possibilities, and in ecent work[3] has shown that a comparison of the ntropies of azulene and naphthalene (which has milar lattice dimensions) appears to confirm the resence of some disorder in the azulene crystal.

We have now made a further examination of the crystal structure of azulene and have obtained the ell dimensions $a = 7{\cdot}91 \pm 0{\cdot}02$, $b = 6{\cdot}00 \pm 0{\cdot}02$, $= 7{\cdot}84 \pm 0{\cdot}02$ A., $\beta = 101°\ 30'$. This unit cell contains two molecules of $C_{10}H_8$ and the ($h0l$) eflexions are absent when h is odd. We have looked or the ($0k0$) spectra carefully up to the seventh order, iving long exposures on oscillation photographs, but have only been able to find (020) with F about 15·5 and (060) with F about 1·7. What appeared to be a peak (010) was observed with copper radiation, but his is probably spurious and could not be repeated with iron radiation.

So far our work is in good agreement with previous esults and suggests the space group $P2_1/a$, although only two ($0k0$) reflexions can be recorded. To obtain urther evidence we have applied the statistical tests of Wilson[4] and Howells[5] to the ($h0l$) spectra, and he results indicate quite strongly that the projection of the structure on (010) is non-centroymmetrical. If this conclusion is accepted, it means hat the ($0k0$) absences are accidental and that the pace group is probably Pa (C^2_s) with two asymmetric molecules in the unit cell.

Proceeding on this assumption, a trial structure based on the chemical formula was postulated and efined by the method of difference syntheses. Good greements were soon obtained for all the ($h0l$) pectra, and an electron-density projection of the tructure on (010) is shown in Fig. 1 At this stage he average discrepancy between observed and calulated structure factors in the ($h0l$) zone is 11 per cent. The other zones also give substantial agreements and are being further refined.

The positions of the molecules in the unit cell are milar to those of the naphthalene structure[6], lthough the azulene molecules have a rather different rientation. Their position with respect to the glide plane is such as to create an almost exact halving of the ($0k0$) spectra ; but this halving is, of course, ccidental in the sense that it is not necessarily mposed by the symmetry elements of the space roup. From Fig. 1 it is seen that the molecular lane is steeply inclined to (010), as in the corresponding naphthalene structure, and this prevents clear esolution of all the atoms. Nevertheless, the form of the molecule, consisting of a fused five- and seven-membered ring system, can be clearly seen. Although some disorder may be present in the structure, it does not seem to be enough to prevent a full determination of the molecular structure by the X-ray method.

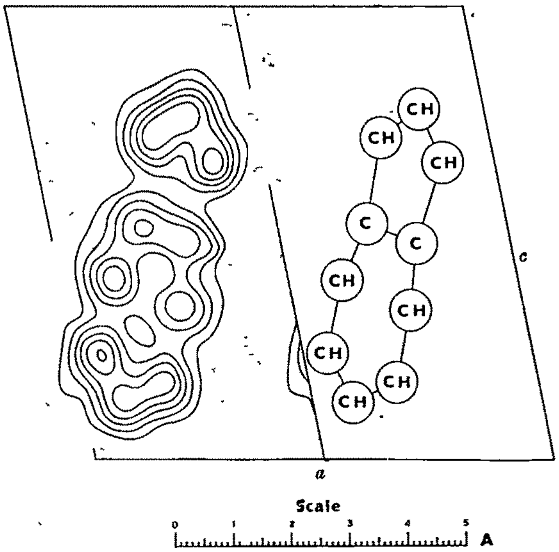

Fig. 1. Projection of the azulene structure on (010)

The peak values of the electron density are seen to vary in an interesting manner on the different atoms ; but neither these variations nor the variations of bond-length which can be obtained after allowing for the orientation are significant at the present stage of refinement. As the structure is non-centrosymmetric, it is expected that this refinement process will have to be carried quite far, probably with the use of full three-dimensional data, before really significant and chemically interesting results are obtained. This work is now proceeding.

We are indebted to Prof. Wilson Baker and to Dr. E. Clar for supplies of pure azulene.

Radioactivity of Iron Meteorites by the Photographic Method

We wish to present the preliminary results of a study of the α-radioactivity of iron meteorites by the method of nuclear emulsions.

The important work of Paneth's group[1] on the helium ages of iron meteorites shows uranium and thorium contents of 0·1–1 × 10^{-8} gm./gm. Davis's radium determinations on seven iron meteorites gave uranium equivalents of the same order of magnitude[2].

The meaning of the helium ages has been discussed by Urey[3,4]. He states that on thermodynamical grounds[3,5] one would expect in the metallic phase of meteorites concentrations of uranium and thorium considerably lower than 10^{-9} gm./gm. On the other hand, Urey[3] and Singer[6] have suggested that radiogenic helium could be preferentially lost as a result of a localization of radioactive elements in the boundaries between crystals. In such an event, ages by the helium method would be too low.

Recently, Reed and Turkevitch[7] have used activation methods to determine the uranium content of two iron meteorites. Their results are lower than those of Paneth's group by at least one order of magnitude.

The nuclear emulsion method appears particularly appropriate for such measurements of very low radioactivity, especially when one deals with the localization of radioactive elements. In spite of the fact that definite conclusions cannot, as yet, be drawn, we think it worth while to give a progress report on our work on this problem, pointing out, in particular, the technical difficulties and the limitations of the method. A detailed account will be published elsewhere.

We have studied so far two iron meteorites: Toluca (Hamburg) and Carbo. Uranium and thorium contents have been determined by Dalton *et al.* on other samples of these octahedrites[8]. We have counted and localized two thousand α-particle tracks, on an area of 32 cm.^{2} of plates (Ilford *C*2, exposure time 140 days). Range-distribution analysis indicates that more than 85 per cent of the α-particles counted must result from surface contamination of the samples by polonium, in spite of many precautions to prevent it. However, this contamination corresponds to no more than 100 polonium atoms (10^{-16} curie) per sq. cm.

To reduce as much as possible the effect of the surface contamination in determining the uranium and thorium content, only tracks with a residual range in the emulsion of less than 15 microns were taken into account. This being the shortest range in the uranium and thorium families, tracks of less than 15 microns must have originated within the sample. Uranium and thorium contents, calculated in this way, are given in Table 1; it must be kept in mind that these are maximum values.

We have also determined a maximum value of 10^{-7} gm./gm. for the uranium and thorium concentration in the troilite phase of Toluca. We conclude that the uranium and thorium found by Paneth's group in Toluca (Hamburg) is not all localized in the troilite phase, since the resulting specific activity should have been easily detected under our experimental conditions. The relatively important degree of contamination has prevented us so far from deciding if the activity is concentrated in the inter-crystal boundaries.

Our upper limit of $0{\cdot}6 \times 10^{-8}$ gm. uranium/gm. agrees with the results of Paneth and co-workers, but, of course, does not contradict those of Reed and Turkevitch. We hope in further experiments to lower our level of contamination by a factor of ten, which should clearly throw our findings in favour of one or the other of these contradictory results, and further our knowledge on the distribution of radioacti
elements in meteorites.

We wish finally to point out that a lower limit
the uranium and thorium concentrations in Tolu
(Hamburg) can be obtained from its minimum rad
genic helium content[1], if we assume for it an a
of $4{\cdot}5 \times 10^9$ years[9] and if we suppose that
radiogenic helium was lost. This comes out a
$U > 1{\cdot}5 \times 10^{-11}$ gm./gm.; $Th > 2 \times 10^{-10}$ gm./g

Table 1. URANIUM AND THORIUM CONTENT (in 10^{-8} gm./gm.)

Electric-breakdown Tracks in 'Perspex'

MASON[1] has shown that the short-time elect
strength of polythene and other solid insulati
materials may have an average value many times l
than the intrinsic breakdown stress, because of t
distortion of the field and the high local stress at t
ends of discharges. Still to be explained, howev
is the steepness of the breakdown voltage/ti
characteristic for 50 c./s. stresses of a few seco
duration.

In order to investigate this problem, polythe
'Perspex', and polystyrene specimens have b
broken down between needle-point electrodes in hi
quality transformer oil at room temperature, p
vision being made to short-circuit the breakdo
path in the specimen within a few micro-seconds
the breakdown. In this way, the nature of the bre
down channels may be observed in the absence
damage resulting from the passage of fault curr
(Fig. 1). A similarity, most pronounced in
'Perspex' specimens, has been noted between
nature of the breakdown propagation and that
the streamer breakdown of air.

A ciné-film has been made of a breakdown
'Perspex' sheet, ½ in. thick, disposed as shown
Fig. 2, at 50 kV. r.m.s., 50 c./s., and the last sect
of this film is reproduced in Fig. 3. Each fra
corresponds to successive third half-cycles, and
time taken for the breakdown to be propaga
through the specimen was about 15 sec. When
film is projected at two frames per second (⅛ of nor
speed) a step-by-step erosion from alternate poi
(probably as each becomes positive) may be seen

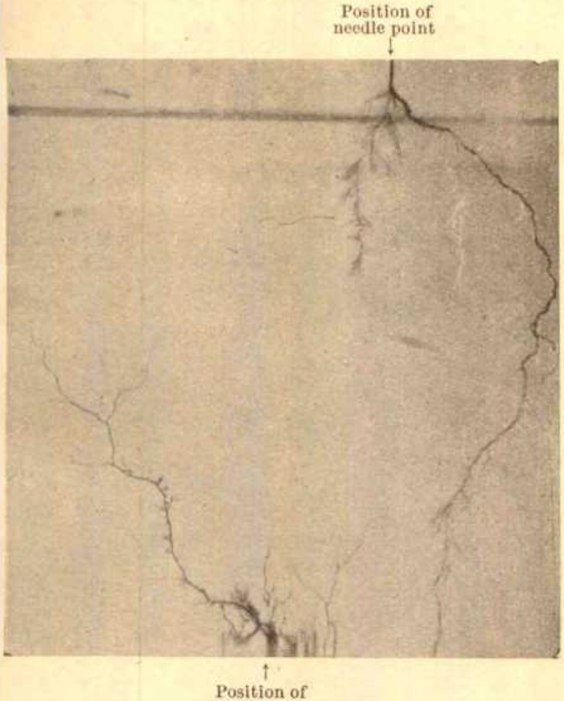

Fig. 1. Breakdown tracks in 'Perspex' undamaged by fault current

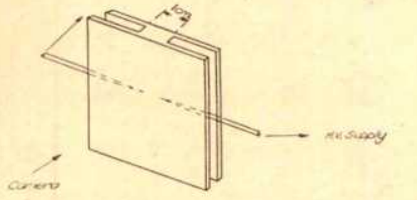

Fig. 2. Arrangement of specimen for ciné film of 50 c./s. breakdown in 'Perspex'

The evidence suggests that a possible mechanism f breakdown propagation from pointed electrodes that is, needles or the ends of discharge streamers) s the flow of free electrons towards the positive lectrode, permanent damage to the material occurring ear to the ends of the channels where the current lensity is sufficiently high. The electrons may be xcited from imperfection levels, possibly by radiation rom discharges. This suggested mechanism would ccount for the random nature of many of the channels nd for the fact that channels from opposite electrodes ollow separate paths.

The breakdown mechanism described is observed o be a step-by-step process, cycle by cycle. The umber of cycles to breakdown depends on the current lensity in the discharge channel, which itself depends upon the excitation and subsequent acceleration of initially trapped electrons. Because the current would depend strongly on the stress, the time to breakdown falls rapidly as the stress is increased.

Since this communication was prepared, my attention has been directed to some similar work which has just been published in Germany[2].

Damping of the Earth's Free Nutation

The 'free nutation' of the Earth is a motion of the Earth's instantaneous axis of rotation around its mean position. The poles (intersections of the axis with the Earth's surface) describe changing orbits with the 'Chandler period' of about fourteen months. Every six or seven years the amplitude of these orbits reaches a maximum of up to ten metres and then decreases almost to zero. Following Jeffreys[1], Bondi and Gold[2] have considered that the free nutation has a characteristic damping time of the order of ten periods. They find that such heavy damping cannot arise from internal motion of the core or from relative motion between core and mantle, and conclude that it results from non-elastic behaviour of the mantle.

However, I doubt that the damping is as heavy as they suppose. Schweydar[3] has shown that the form and amplitudes of the observed complicated motion of the poles can be explained with a good approximation as a beat phenomenon between the free Chandler period of the Earth of about fourteen months and a periodic annual displacement of the Earth's axis of inertia. He found that the average annual movements of air masses from one hemisphere to the other alone should produce displacements of the poles of inertia with an average annual range of roughly three metres, which is enough to explain the amplitude of the nutation; there are appreciable variations from year to year due to changes in the meteorological conditions. On the other hand, observations of the uplift in formerly glaciated areas and the existence of deep-focus earthquakes indicate[4] that the mean time of viscous relaxation in the upper 700 km. of the Earth's mantle is at least of the order of a hundred years. From this a coefficient of viscosity of the order of at least 10^{21} poises may be derived. The period of only about seven years with which the amplitudes of the free nutation increase and decrease is probably short compared with the damping time of the nutation. Moreover, the energy transfer from atmospheric and other processes to the Chandler motion is unknown. Con-

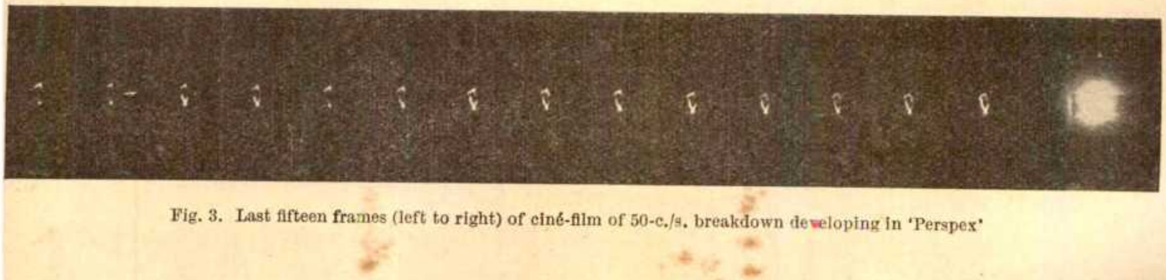

Fig. 3. Last fifteen frames (left to right) of ciné-film of 50-c./s. breakdown developing in 'Perspex'

sequently, it does not seem possible to interpret the decay curve of the nutation and to discriminate the effect of damping from the beat phenomenon.

A New Theorem in Electrostatics and its Application to Calculable Standards of Capacitance

Although capacitance has the dimensions of length only, usually two or more separate lengths are needed to compute the capacitance of the various forms that have been used as standards. In seeking a form of calculable capacitor involving a minimum number of determinations of length, we have investigated cylindrical systems and have discovered a particular class of capacitor in which the capacitance depends on one length only to the first order. For example, if a square cylinder is constructed from four conducting planes which are insulated from each other at the corners, then the direct capacitances per unit length of cylinder, between each pair of opposing inside faces, are equal and independent of the size of the square. This direct capacitance was calculated as $\frac{\ln 2}{4\pi^2}$ cm./cm., and it was also calculated that if the cross-section was rectangular with a ratio of sides of $1 + \delta$, $\delta \ll 1$, then the mean of the two cross-capacitances was $\frac{\ln 2}{4\pi^2}\{1 + 3{\cdot}45\,\delta^2 + \ldots\}$ cm./cm. These calculations confirmed that, providing the asymmetry was not too great, a standard capacitor could be constructed which required only one length measurement for the computation of its capacitance. The length of the capacitor may be defined by insulating a length of one face from the remainder of that face, which remainder functions as a guard.

The capacitance per unit length and asymmetry effects were calculated for a number of other symmetrical cross-sections. These calculations all gave the same value, namely, $\frac{\ln 2}{4\pi^2}$ e.s.u., as the capacitance per unit length, and this result led one of us (D. G. L.) to propose and prove the following theorem:

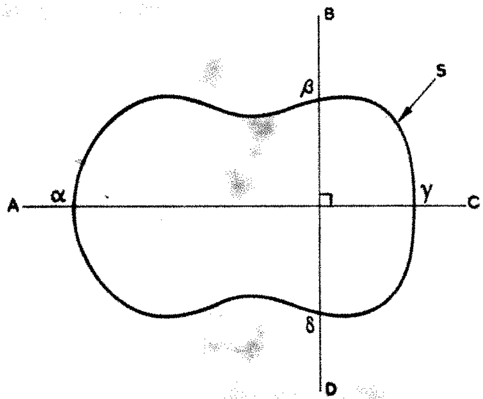

Fig. 1. Cross-section of cylindrical shell

Let the closed curve S (see Fig. 1) be the cross-section of a conducting cylindrical shell, which cross-section has one axis of symmetry AC but is otherwise arbitrary. Further, let this shell be divided into four parts by two planes at right angles, the line of intersection of the planes being parallel to the generators of the cylinder, and one of the planes containing the symmetry axis AC. Then the direct capacitance, per unit length of the cylinder, between opposing parts of the shell (for example, $\alpha\beta$ to $\gamma\delta$), due to the field inside (or outside) the shell, is a constant:

$$C_0 = \frac{\ln 2}{4\pi^2}\ \text{e.s.u.} = 0{\cdot}0175576\ \text{e.s.u.}$$

As a consequence of this theorem, it is clear that the choice of the cross-section, for a cylindrical standard capacitor, is limited only by the requirements that the cross-section have one axis of symmetry and that it be a closed curve.

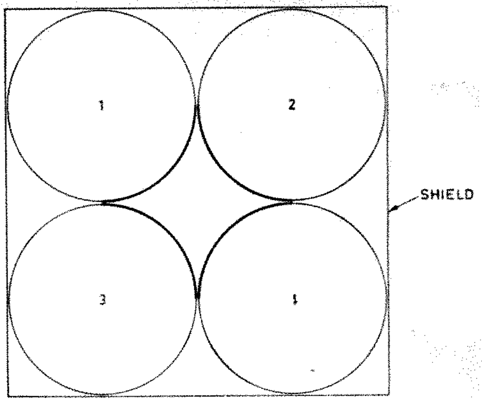

Fig. 2. Cross-section of experimental capacitor

A cross-section which satisfies these requirements and at the same time is easy to realize in practice is that of the space between four circular cylinders the axes of which are arranged to lie at the corners of a square (see Fig. 2). Accordingly, a capacitor of nominal capacitance 1 pF (equivalent length, 20·151 in.) was constructed, using four pieces of stock silver-steel rod (nominal diameter, 15/16 in.) for the cylinders and suitably shielded externally so that only the inside field contributes to the capacitance. Two of the rods (2 and 4) were provided with end-guards to define their lengths and the rods were insulated from each other by mica spacers (0·004 in. thick) placed in the end guard region.

The cross-capacitances (1–4 and 2–3) were measured, and although they differed from the mean capacitance by as much as 0·3 per cent, this mean agreed to within one part in ten thousand with the capacitance calculated from the measured lengths of the guarded rods, due allowance being made for the dielectric constant of the air. It is proposed to construct a precision capacitor based on this design.

Full details of these investigations will be published elsewhere.

Oxidation as a Source of 'Anomalies' in Amylose

Peat and his collaborators[1-3] have found that amylose prepared from potato, sago, maize and apioca starch cannot be degraded by purified β-amylase or phosphorylase to an extent greater than about 70 per cent. Retrogradation of the amylose, which might have accounted for this, has been ruled out[2], leaving the implication that a proportion of the molecules of amylose have either an anomalous non-educing end-group, or an anomalous group at some point along the chain. Peat, Thomas and Whelan[4,5] ind that the anomaly can be removed by treating amylose with a β-glucosidase, termed *Z*-enzyme, and herefore suggest that it may result from the presence f a single glucose residue attached to the main hain by a link of β-configuration.

An alternative possibility is that the anomaly is an artefact introduced during the preparation of the amylose. This might happen through air-oxidation[6] during the isolation of the amylose, or, if the starch s a commercial sample, during the industrial processing of the starch.

To test this possibility, starch, freshly prepared from potatoes, was dispersed in neutral 1 per cent odium chloride solution in the absence of oxygen, nd fractionated as described previously[7]. Samples f the amylose fraction ('blue value' 1·3) were then reated with oxygen and their susceptibility to rystallized potato phosphorylase[8] compared with hat of the untreated amylose.

The oxidized samples were prepared by blowing xygen at 95° C. through portions of the amylose issolved in (*a*) 0·5 *M* sodium hydroxide and (*b*) 0·01 *M* phosphate buffer, *p*H 7·1. The intrinsic viscosity f the amylose (measured in 0·5 *M* sodium hydroxide t 20° C.) fell in (*a*) from 3·09 to 1·13 in a treatment asting 20 min., and in (*b*) to 0·98 in 8·75 hr. To nable a strict comparison to be made, a sample f the parent amylose was hydrolysed to an intrinsic iscosity of 1·02 by treatment with 0·1 *M* hydrohloric acid at 60° C. for 75 min. in an atmosphere f nitrogen. The three samples of degraded amylose ere precipitated from neutral solution with butanol, nd solutions prepared from the precipitates by team-distillation under nitrogen.

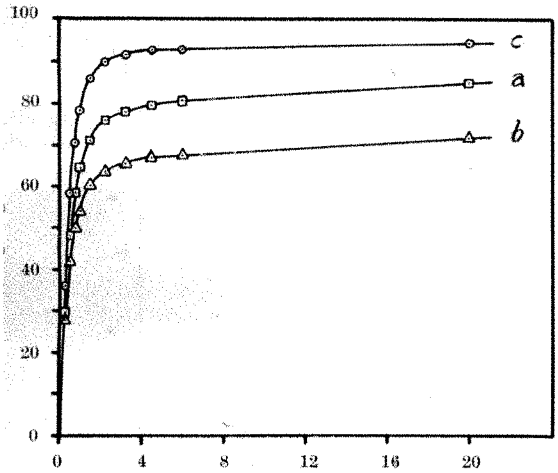

Fig. 1. Phosphorolysis of amylose. Curve (*a*), amylose previously oxidized in 0·5 *M* sodium hydroxide to $[\eta] = 1 \cdot 13$; (*b*) amylose previously oxidized at *p*H 7·1 to $[\eta] = 0 \cdot 98$; (*c*) amylose previously hydrolysed to $[\eta] = 1 \cdot 02$

When incubated with phosphorylase in 0·2 *M* phosphate buffer, *p*H 6·6, at 38° C., the parent amylose was degraded smoothly to 90 per cent of theoretical. Degradation was measured by staining samples with iodine and measuring the optical density at 680 mμ. In a control to which phosphate was not added, there was no change in 24 hr. in intrinsic viscosity or in the optical density of the iodine stain. The phosphorylase was therefore free from α-amylase and *Q*-enzyme.

The three samples of degraded amylose were incubated simultaneously with phosphorylase under identical conditions. The results are shown in Fig. 1, in which degradation, expressed as the percentage fall in optical density of the iodine stain, is plotted as a function of time. It can be seen that a limit was quickly approached in all three cases, and from the values at 6 hr. the limit approximated for the hydrolysed sample to 92·8 per cent, for the sample oxidized in alkaline solution to 80·7 per cent and for the sample oxidized in neutral solution to 67·4 per cent of theoretical.

These results have been confirmed by duplicate experiments, and it is therefore clear that anomalies which limit phosphorolysis can be introduced into amylose by molecular oxygen, and also that such anomalies are not present to any appreciable extent in native amylose.

Two of us (H. B. and N. D. S.) are grateful to the Department of Scientific and Industrial Research for maintenance awards.

Photochemical Oxidation of Alcohols by Dichromate

In a recent communication in *Nature*[1] a table is presented of the reactivities per —OH group of a series of alcohols towards hydrogen-atom abstraction by photo-excited quinones. These values are very close to the relative reactivities of the alcohols to photo-excited dichromate solutions, for which approximate figures are available (Table 1)[2].

Table 1

Alcohol	Reactivity to	
	Quinone	Dichromate
Methanol	0·12	0·3
Ethanol	1·0	1·0
n-Propanol	1·53	1·5
iso-Propanol	2·14	2·0
Glycerol	0·28	0·5

It might be concluded from this that the first reaction in photochemical oxidation by the dichromate ion is hydrogen atom abstraction from the organic molecule.

Mechanism of Inactivation of Tobacco Mosaic Virus by X-rays

INACTIVATION of tobacco mosaic virus by X-rays has been studied by Gowen and Price, by Lea and associates[1] and by us[2]. The fraction surviving is an exponential function of dose with D_0 about $2 \cdot 3 \times 10^5$ r. This value corresponds to a target 3000 A. long and about 40 A. in diameter[2].

If the nucleic acid is the target, as proposed by Epstein[3], then it is possible that X-rays produce their lethal effect by breaking a nucleic acid chain. If this is true, then nucleic acid isolated from heavily irradiated tobacco mosaic virus ought to have a lower average particle-length than nucleic acid from unirradiated virus.

Since nucleic acid isolated from tobacco mosaic virus is a long, thin, fairly rigid rod[4,5], this theory can be put to test by measuring the intrinsic viscosity of isolated nucleic acid. To this end, 2 per cent solutions of tobacco mosaic virus were subjected to various doses of X-rays, and the nucleic acid was isolated by the method of heat denaturation[5]. The concentration of nucleic acid was determined from the height of the absorption maximum at 2570 A. The freedom from protein was verified by noting that the ratio of the extinction coefficients at 2600 and 2800 A. agreed closely with that of tobacco mosaic virus nucleic acid and differed greatly from that of the virus protein[6]. Results are shown in Table 1.

Table 1. INTRINSIC VISCOSITY OF TOBACCO MOSAIC VIRUS NUCLEIC ACID FOLLOWING X-IRRADIATION

Intrinsic viscosity (ml./gm.)	Radiation dose (10^6 r.)	Intrinsic viscosity (ml./gm.)	Radiation dose (10^6 r.)
84	0	65	0·46
77	0	37	1·85
74	0	40	1·85

Nucleic acid isolated from X-irradiated virus has a lower intrinsic viscosity and, therefore, a lower average particle-length than that isolated from unirradiated virus. Therefore, the action of X-irradiation is to break the nucleic acid rods. That this breakage occurs as a result of damage inside the virus particle is indicated by the observations that heavily irradiated tobacco mosaic virus possesses essentially the same sedimentation-rate, intrinsic viscosity and electron image size as unirradiated virus. One can show, on the basis of simplified Simha theory, that the effect of breaking once each particle in an initially uniform distribution of rods, with the position of the break being equally likely at any point along the rod, would be to reduce the intrinsic viscosity to exactly one-half of its initial value. This calculation indicates that the order of magnitude is 1 for the number of breaks per rod associated with irradiation doses of about eight times the value of D_0 for inactivation.

This result is consistent with the view that the lethal action of X-rays on tobacco mosaic virus is the breaking of a single molecular chain anywhere in the nucleic acid. A possible reason for the discrepancy between the lethal dose and the dose required to break the rod is that the structure of ribose nucleic acid may be a coil of several strands.

An important deduction from these findings is that the biological activity of tobacco mosaic virus depends on the physical intactness of the nucleic acid. That a comparable degree of intactness of the protein is not required is indicated by the results reported by Schramm[4], to the effect that tobacco mosaic virus which has lost considerable protein still shows full biological activity.

A New Unidentified Indole Hormone in Maryland Mammoth Tobacco

IT has been reported previously[1] that the short-day plant, Maryland Mammoth tobacco, will flower under long day-lengths (14½–15½ hr.) if exposed to varying dosages of γ-rays. Recently, we have been investigating the effect of γ-radiation on the endogenous level of the indole compounds occurring naturally in leaf, stem, root and apical tissues of γ-irradiated and normal Maryland Mammoth tobacco. Large quantities of these tissues (300–1,000 gm.) have been extracted with absolute ethanol, employing a technique for extraction and paper chromatography as described previously[2]. Microlitre quantities of the extracts, after acidification and extraction with ethyl ether, were spotted on Whatman No. 1 filter paper and chromatographed in seventeen different solvents. Colours were developed with *p*-dimethylaminobenzaldehyde. 3-Indoleacetic acid was not detected in any of more than thirty-five individual extractions of leaf, stem, root or apical tissues of normal or γ-irradiated Maryland Mammoth tobacco. However, an unidentified indole compound was found in the leaf and apical extracts with R_F values as shown in Table 1.

Eluates of chromatograms containing the unknown have been assayed for activity in the split-pea curvature and tomato-petiole epinasty test. The compound was found to possess activity in both these biological assays. In addition, through the courtesy of Dr. K. V. Thimann and Dr. B. Stowe, of Harvard University, eluates of chromatograms containing the substance were tested and found to

Table 1. R_F Values in Six Solvents for Various Known Indole Derivatives occurring naturally and for an Unidentified Indole Hormone in Normal and γ-Irradiated Maryland Mammoth Tobacco

Compound	2-Propanol/ ammon./water (80 : 5 : 15)	2-Propanol/ ammon./water (10 : 1 : 1)	Ethanol (70 per cent)	Water	Water (chamber equilibrated with hydrochloric acid)	Water (chamber equilibrated with ammon. hydrox.)
Unidentified indole compound of tobacco	0·98	0·98	0·97	0·67	0·61	0·82
3-Indoleacetic acid (Eastman Kodak)	0·52	0·50	0·78	0·80	0·65	0·98
3-Indoleacetonitrile (Carbide and Carbon Chemicals Co.)	0·98	0·98	0·95	0·40	0·65	0·60
Ethyl ester of 3-indoleacetic acid	0·98	0·98	0·94	0·69	0·78	0·87

be active in the *Avena* curvature and straight-growth tests.

The compound is stable to alkaline treatment, labile to acids, possesses an ultra-violet absorption spectrum indicative of an indole ring system, and gives positive colours with Salkowski, Ehrlich's or Hopkins–Cole reagents.

In view of the absence of 3-indoleacetic acid in Maryland Mammoth tobacco leaf and apical tissue, and the presence of this physiologically active indole compound, it appears that we are dealing with a hitherto undescribed naturally occurring plant-growth hormone. The compound is not 3-indoleacetonitrile, which lacks activity in the pea-curvature test, and it does not appear to be the ethyl ester of 3-indoleacetic acid which, unlike the unknown, is hydrolysed by alkalis.

With the recent report of Luckwill and Powell[3] on he absence of 3-indoleacetic acid in the apple, vidence is accumulating that the hormonal regulaion of growth in plants may not be restricted solely o the influence of 3-indoleacetic acid.

Details of this investigation will appear in the April–June issue of the *Contributions from Boyce Thompson Institute*.

Inhibitory Action of Chlorpromazine on the Oxidation of D-Amino-Acid in the Diencephalon Part of the Brain

AMONG several substances examined in our laboratory for their influence on the activity of D-amino-cid oxidase, chlorpromazine (N-(3′-dimethylamino-ropyl)-3-chlorophenothiazine hydrochloride) was und to be a powerful inhibitor of this enzyme. The inhibitory mechanism was investigated using a urified oxidase enzyme system and Warburg manoeter, and the kinetic study carried out. D-Amino-id oxidase protein was prepared from hog kidney y the method of Negelein and Brömel[1]. Each zyme system consisted of apo-enzyme (protein *E*), 6×10^{-7} mole of flavin adenine dinucleotide repared by the method of Yagi *et al.*[2], $6 \cdot 25 \times 10^{-2}$ ole of D-alanine. Amounts of chlorpromazine upplied by Rhône-Poulenc-Specia) ranging from $\times 10^{-5}$ to 4×10^{-6} mole were added to these zyme systems.

The relation between D-amino-acid oxidase activity and flavin adenine dinucleotide concentration is

$$v = \frac{Vf}{K_F + f} \qquad (1)$$

where v is the reaction velocity in the presence of a concentration f of flavin adenine dinucleotide, V is the maximum velocity obtained by increasing the concentration of flavin adenine dinucleotide, and K_F is independent of f and V. Using this formula, the dissociation constant of flavin adenine dinucleotide with oxidase protein was calculated as $1 \cdot 1 \times 10^{-7}$ *M*.

If an inhibitor acts by combining with oxidase protein competitively with flavin adenine dinucleotide or by forming a complex with flavin adenine dinucleotide, and $K \gg K_F$, the activity of the enzyme can be represented by the following formula, as described by Burton[3]:

$$v = \frac{Vf}{K_F\,(1 + i/K) + f} \qquad (2)$$

where i is the concentration of inhibitor and K is its dissociation constant from its complex with oxidase protein or with flavin adenine dinucleotide.

If v_0 is the reaction velocity in the absence of inhibitor, from equation (2)

$$\frac{v_0}{v} = 1 + \left\{1 - \frac{v_0}{V}\right\}\frac{i}{K} \qquad (3)$$

and K can be evaluated.

In an experiment, the values of v_0/v plotted against the concentration of chlorpromazine (i) gave the straight line, the slope of which was $1 \cdot 8 \times 10^4$ l./mol.; and the values of v_0 and V were 41·5 µl. and 70·5 µl. of oxygen uptake in 30 min. respectively. From these values, K was calculated as $2 \cdot 3 \times 10^{-5}$ mol./l. The possibility of a complex forming between chlorpromazine and flavin adenine dinucleotide was excluded by measuring extinction and fluorescence.

It is therefore concluded that the inhibitory mechanism of chlorpromazine on D-amino-acid oxidase can be attributed to competition with flavin adenine dinucleotide.

These observations suggested that chlorpromazine inhibits the flavin enzymes in brain tissue. As chlorpromazine is believed to have an influence on the diencephalon, the inhibitory action of chlorpromazine on enzymes with which flavin is concerned has been investigated. The activity of a homogenate of the diencephalon (comprising the thalamus, metathalamus epithalamus and posterior part of hypothalamus) was therefore investigated. The oxygen uptake of a homogenate of the diencephalon freshly excised from a dog was measured manometrically. The endogenous respiration of the homogenate was inhibited by cyanide. In the presence of cyanide, it was able to catalyse the oxidation of D-alanine, and was activated by the addition of flavin adenine dinucleotide. It was markedly

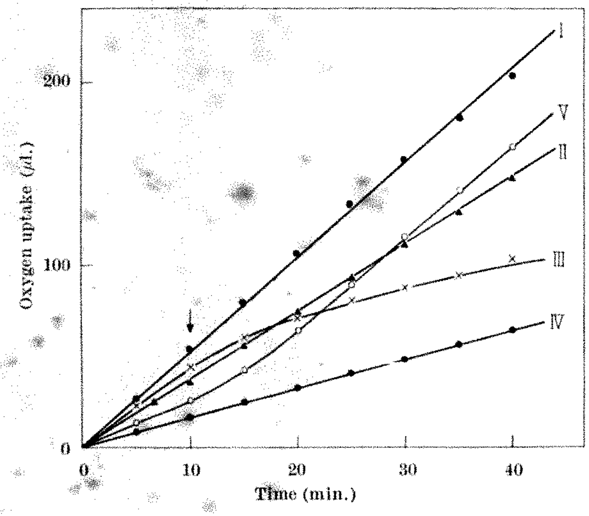

Fig. 1. Inhibitory action of chlorpromazine on the oxidation of D-alanine by a homogenate of diencephalon. Curves I–V show the oxygen uptake of the following reaction mixtures in a total volume 1·8 ml. in each cup: Curve IV, pyrophosphate homogenate (pH 8·3) of 500 mgm. of wet diencephalon and M/900 potassium cyanide (final concentration). Curve II, same as IV + D-alanine (final concentration, $5 \cdot 5 \times 10^{-2}$ M). Curve I, same as II + flavin adenine dinucleotide (final concentration, $1 \cdot 4 \times 10^{-5}$ M). Curve III, same as II + flavin adenine dinucleotide (final concentration $1 \cdot 4 \times 10^{-7}$ M) + chlorpromazine (final concentration 2×10^{-5} M) after 10 min. Curve V, same as II + chlorpromazine (final concentration, 2×10^{-5} M) + flavin adenine dinucleotide (final concentration, $1 \cdot 4 \times 10^{-5}$ M) after 10 min.

inhibited by the presence of chlorpromazine, and was recovered by the addition of flavin adenine dinucleotide, as shown in Fig. 1. The activity in this reaction mixture can be attributed to D-amino-acid oxidase in this tissue.

From these results, it is considered that chlorpromazine will decrease the oxidation of the diencephalon by inhibiting its flavin enzymes in competition with flavin adenine dinucleotide. These results may have some connexion with the pharmacological action of chlorpromazine.

Glucagon and the Regulation of Carbohydrate Metabolism

THERE is considerable experimental evidence that glucagon (hyperglycæmic factor of the pancreas) is a true hormone which originates in the α-cells of the islets of Langerhans[1]. Its isolation and crystallization were reported in 1953 [2]. The crystalline material appears to be a simple protein with a molecular weight of approximately 4,200 and an amino-acid content which differs significantly from that of insulin[3]. Minute doses of crystalline glucagon (0·1γ in the cat) cause a significant rise in blood sugar[3]. This effect is probably brought about by a stimulation of liver glycogenolysis, since glucagon has been shown to increase the net synthesis of liver phosphorylase[4]. Further than this, little is known abo the action or physiological role of glucagon. Curre speculation revolves about three possibilities: (*a*) th glucagon is an anti-insulin hormone[1], (*b*) that it is insulin synergist[5], or (*c*) that it has no significa function in the control of carbohydrate metabolism

I wish to report briefly some experiments on t effect of glucagon and insulin alone and in combin tion on the utilization of peripheral glucose, and propose a theory of the role of glucagon in the regul tion of carbohydrate metabolism. Detailed expe mental results are being published elsewhere[7].

Fifty-six men (ages twenty-one to forty-seve considered normal with respect to carbohydra metabolism, and in good general health, were studi under controlled basal conditions. All subjects we kept under hospital conditions and on a high carb hydrate diet for several days before the experiment which were done in the morning after a 14-hr. fa and 30–60 min. of bed rest in a special room. T effects of glucagon and/or insulin on arterial (capillar and venous blood-sugar levels were studied for 6 110 min. following a control period of 30–60 mi during which glucose alone was infused. (Glucag and glucagon-free insulin were kindly supplied Drs. Behrens and Kirtley, of the Eli Lilly C Frequent blood samples (30–40 per subject) we drawn without stasis and analysed for glucose the Nelson–Somogyi method[8].

The results showed that glucagon causes a high significant increase ($P = 0 \cdot 001$) in the differen between arterial and venous glucose. These findin confirm results previously reported from this la oratory using a different experimental procedur Insulin also increased the difference between arteri and venous glucose significantly ($P = 0 \cdot 01$), as wou be expected. When both insulin and glucagon we administered together, the differences between arteri and venous glucose were significantly great ($P = 0 \cdot 001$) than those with either glucagon insulin alone. Fig. 1 summarizes the results fro the three experimental groups with respect to valu for the ratio of the difference between arterial a venous glucose to the concentration of arteri glucose, which have been shown to be proportion to the specific rate constant of peripheral gluco utilization under the special conditions of t experiments[7b].

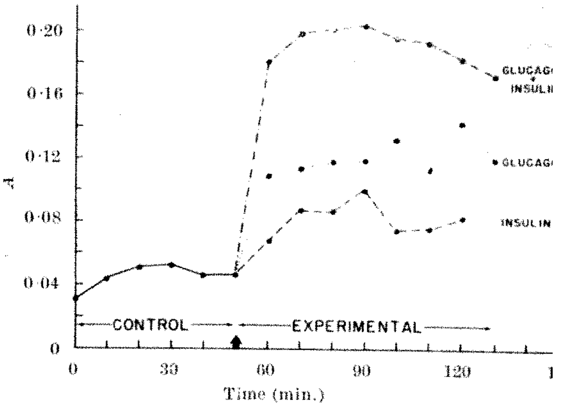

Fig. 1. Each point of control period represents the median value of 54 subjects, whereas each point of the three experimental groups represents the median of 12 subjects. The ratio of the differences between arterial and venous glucose to the concentration of arterial glucose is proportional to the specific rate constant of utilization of peripheral glucose. *A*, arterial glucose concentration; *V*, venous glucose concentration

These findings suggest that (*a*) glucagon has a dual, integrated action, namely, the release of liver glycogen and the enhancement of peripheral glucose utilization, and that (*b*) glucagon and insulin may function jointly to accelerate the peripheral utilization of glucose. Since the two hormones have opposing actions on blood glucose and the levels of liver glycogen, each is well suited to complement the effect of the other in the task of maintaining these two reservoirs of body glucose constant in the face of an accelerated rate of utilization of peripheral glucose.

This mechanism remains to be clarified. Studies in the depancreatized dog[7a] indicate that the effects are not due to a secondary release of insulin. Furthermore, the increases in the ratio of the difference between arterial and venous glucose to concentration of arterial glucose values with glucagon were significantly greater ($P = 0{\cdot}001$) than those observed with comparably high blood-glucose levels obtained by glucose alone[7a]. Hence the hyperglycæmic action *per se* of glucagon is not an adequate explanation for the results observed. Preliminary experiments in the hepatectomized dog (Elrick, H., Rachiele, F., Stoll, F., and Arai, Y., unpublished observations) suggest that the liver is necessary for the enhancing effect of glucagon on peripheral glucose utilization.

Spasmolytic Effect of Cerebral Tissue Extracts

USING isolated segments of the guinea pig ntestine suspended in oxygenated Tyrode solution t 35° C., strong contractions inuced by acetylcholine and adenoine triphosphate were relaxed by introducing concentrated extracts of at brain in Tyrode solution[1].

When dried red-cell stroma extracted with Tyrode solution was imilarly tried, relaxation of acetylholine contractions occurred immediately, but adenosine triphoshate contractions were not afected. Investigation was then arried out into the possible presence of a relaxing agent other han choline esterase in brain xtracts.

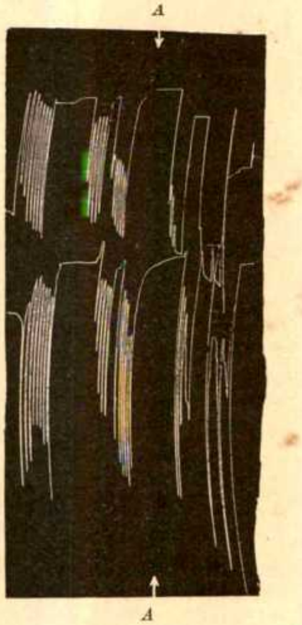

Fig. 1. Trendelenburg's preparation. Intraluminar pressure = 3 cm. water. Upper tracing: peristalsis. Lower tracing: longitudinal movement. At *A*, 0·4 μgm./ml. crude sphingosine (*p*H 7·4). Duration of tracing, 6 min.

A special extract was prepared from cow brain consisting of crude sphingosine bases[2,3] in Tyrode solution, and this, when added to the guinea pig intestine in an organ-bath to make a final concentration of 0·4 μgm./ml., abolished contractions induced by adenosine triphosphate as well as by acetylcholine in a manner similar to whole brain extracts[1].

Using Trendelenburg's preparation[4], it was shown that peristalsis in the guinea pig intestine was abolished by the extract at a concentration of 0·4 μgm./ml. There was a concomitant loss of tone (Fig. 1). Pendular motility in the isolated rabbit intestine was abolished, in some cases after an initial transient spasm. This preparation also showed reduction in tone (Fig. 2).

A more purified fraction (triacetylsphingosine[2]) showed qualitatively similar effects when tested on the isolated rabbit intestine. Larger amounts of this substance were required to demonstrate a definite effect (16 μgm./ml.) and pendular motility and tone only gradually diminished.

These effects of sphingosine were not reversed in any of the tests by washing away the bases. They

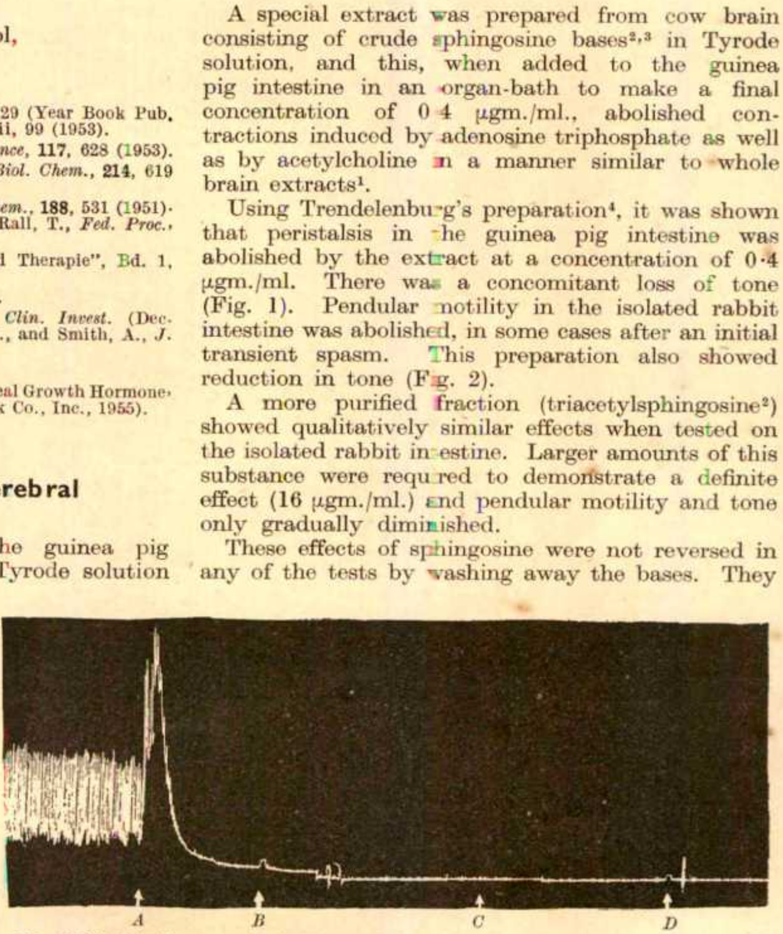

Fig. 2. Rabbit jejunum. At *A*, 0·4 μgm./ml. crude sphingosine (*p*H 7·4). Washing at *B*, *C* and *D*. Duration of tracing, 40 min.

showed the irreversible character observed when atropine is used as an antagonist of acetylcholine in concentrations greater than 0·05 μgm./ml.

It appears, therefore, that sphingosine and allied bases in cerebral tissue may exert a powerful spasmolytic action *in vitro*.

Lipæmia Clearing Action of Sulphated Animal Hyaluronate

Heparin has now been shown to exert a lipæmia clearing action *in vivo*, and is believed to operate primarily by liberating a lipase which catalyses the lipolysis of chylomicrons and low-density lipoproteins[1].

Constantinides and co-workers[2] have shown that several sulphated synthetic polysaccharides, all of which react metachromatically with toluidine blue, may also exert lipæmia clearing activity, apparently operating in the same manner as heparin. Later, Gutmann and Constantinides[3] demonstrated that sulphated alginic acid may even inhibit experimental atherosclerosis in the rabbit. The work of Constantinides and collaborators indicated further that, at least for synthetic polysaccharides, sulphation is an essential for providing these synthetic agents with both their metachromatic staining capacities and their lipæmia clearing activities.

Since heparin is itself a sulphated uronic acid derivative, it was therefore considered possible that other naturally occurring metachromatic staining mucopolysaccharides, and especially those widely distributed in the connective tissues generally and in arterial ground substance in particular, may also exert lipæmia clearing activity. This possibility was tested, in part, by the following experiments.

Twenty-eight male albino Wistar-strain rats weighing 300–400 gm. were used. All animals were starved for 20 hr. before beginning an experiment. Three and a half hours before bleeding by cardiac puncture, they were given 3 ml. of maize oil intragastrically; twenty minutes before bleeding, they were anæsthetized lightly with intraperitoneal pentobarbitone. Immediately before bleeding, they were given a light supplementary ether anæsthesia; the thoracic cavity was then rapidly opened and 3 ml. of right ventricular blood was withdrawn and transferred to chilled heparinized tubes. After centrifuging, an independent observer graded each specimen of plasma, macroscopically, as 0–5 degrees of turbidity.

The preparations tested for anti-lipæmic (or rather anti-chylomicron) action were given in the dosages, by the routes, and at the times before bleeding indicated in Table 1. In addition to this, cortisone, hyaluronidase and toluidine blue were tested for lipæmia clearing activity on a further twenty-seven rats. Details relating to the latter group of substances are not given here, since they all failed both to clear the plasma of macroscopically visible chylomicrons and to prevent the lipæmia clearing activity of intravenous heparin when administered after these preparations. From Table 1 it seems that: (*a*) heparin acts as a lipæmia clearing agent when injected 15 min. prior to death; this confirms previous findings in this regard; (*b*) hyaluronidase fails to inhibit chylomicronæmia when injected intramuscularly prior to fat feeding or intravenously after fat feeding, despite its known effects in mobilizing tissue endogenous mucopolysaccharide; (*c*) non-sulphated, animal umbilical cord hyaluronic acid is apparently erratic in its lipæmia clearing action when given before or after lipæmia has been induced; the sulphated animal umbilical cord hyaluronate is active in the rat when injected both 24 hr. and 1 hr. prior to fat feeding or, alternatively, 3 hr. after fat feeding.

Table 1. Anti-chylomicronæmic Action of Substances tested on Rats given 3 ml. Maize Oil Intragastrically

Preparation	Dosage	Route	Time before bleeding	No. of rats in group	No. of rats with degrees of lipæmia indicated		
					0–1	2–3	4–5*
Nil (controls)	—	—	—	5	1	3	1
Heparin	400 units	Intraven.	¼ hr.	3	3	0	0
Hyaluronic acid	5 mgm.	Intraven.	¼ hr.	6	3	0	3
SO_4-Hyaluronate	2 mgm. + 2 mgm.	Intraperit. Intraperit.	24 hr. 3½ hr.	8	8	0	0
SO_4-Hyaluronate	2 mgm.	Intraven.	¼ hr.	3	3	0	0

* 4–5 indicates marked opalescence of plasma at 3½ hr. after feeding oil.

Preliminary studies on monkeys indicate that plasma, drawn from a fasted animal 15 min. after an intravenous injection of sulphated hyaluronate exerts a lipæmia clearing action when incubated with lipæmic plasma from a control monkey fed with fat. Thus, sulphated hyaluronate also has a lipæmia clearing action *in vivo* in monkeys and probably operates, at least in part, through a similar mechanism to heparin, the sulphated synthetic polysaccharides tested by Constantinides *et al.*[2] and the inorganic salts used by Bragdon and Havel[4].

These findings strongly suggest that heparin is not unique, as a naturally occurring sulphated mucopolysaccharide, in showing lipæmia clearing activity but that other sulphated tissue mucopolysaccharide may have a similar action.

It is tentatively suggested that the deposition of lipid in connective tissue generally, and in arteries in particular, may be a function of the sulphated mucopolysaccharide metabolism throughout the organism. The possibilities of naturally occurring sulphated mucopolysaccharides taking a critical rol in fat deposition in depots and in arteries, normally and in disease processes, and that they may even be capable of promoting the absorption of pathologically deposited lipid in arteries, are being actively investigated in our laboratories.

The expenses of this investigation were defrayed by a generous grant from the Schlesinger Organization, South Africa. We also wish to thank Dr. Robert L Craig, of Messrs. D. G. Searle and Co., Chicago, for providing the sulphated hyaluronate used and Mr. R. N. Tuck and Mr. H. F. Sadler, of Wyeth (Pty.

td., South Africa, for generous assistance with yaluronidase and hyaluronic acid.

Di- and Mono-Taurobilirubin similar to a Directly Reacting Form of Bilirubin in Serum

IN the course of investigations into the colloidal operties of bilirubin, it was found that inhibition the diazo-reaction in acid solution is caused by e association of bilirubin with the formation of lloidal solutions of bilirubin. The diazo-reaction acid *p*H occurs only if bilirubin remains in the onomolecular state[1].

Bile acids become more soluble after combination ith taurin and glycine. The aim of our work was cause a similar change in the chemical constitution bilirubin and to combine both free carboxyls of lirubin with taurin. We used the method described cently for the synthesis of peptides by Boissonnas, ughan and Osato[2]. The same method has been ed in the synthesis of conjugated bile acids by rgström and Norman[3]. In preparing conjugated lirubin the experimental conditions were the same described in that method. We obtained a chemical mpound, ditaurobilirubin, which differed from free lirubin by its solubility in acid solutions. The azo-reaction at an acid *p*H was direct. The spectrum the new compound in dioxan and water was entical with that of free bilirubin. The new pig- ent gave a positive Gmelin reaction, which is, cording to Fischer, typical for bilirubin and other tra-pyrrolic pigments[4]. The infra-red spectrum of e new pigment confirmed the disappearance of free rboxyl groups as compared with bilirubin. The nthetic pigment changed in water medium, pecially when acidified with strong acids, and the llow colour of the solutions changed into green ossibly taurobiliverdin).

When the experimental conditions for the prepara- n were slightly changed, two pigments were tained, one of which, possibly monotaurobilirubin, grated on paper electrophoresis with half the speed the other (possibly ditaurobilirubin). The slowly grating pigment gave a slightly delayed diazo- action as compared with the other.

The pigments were separated by paper chromato- aphy with a chloroform/methanol/acetic acid stem, and in the same way two pigments in addition bilirubin were isolated from the serum of a patient th hepato-dystrophy, and also from various speci- ns of duodenal bile.

In all experiments (using synthetic and natural aterial) the more polar pigment remained at the arting point and gave a direct diazo-reaction. The less polar synthetic pigment migrated with a slightly lower R_F than the natural pigment, free bilirubin migrating with the solvent front. As with direct chromatography of serum bilirubin, reversed phase chromatography of synthetic products, according to Cole, Lathe and Billing[5], yields two pigments besides bilirubin.

The preparation of other similarly substituted bilirubin derivatives has been undertaken. Their chemical properties and elemental analyses will be described elsewhere.

Production of Opacity on Serum Agar Plates by Some Strains of *Staphylococcus aureus*

IN 1941, one of us (A. J. H. T.) observed that about half the strains of *Staphylococcus aureus* isolated from the skin lesions of impetigo contagiosa had two properties not often seen in strains from other sources, namely, the ability (*a*) to inhibit the growth of corynebacteria on solid media, and (*b*) to produce zones of opacity on serum agar plates. In a recent investigation of impetigo in south-east Lancashire, it was found that 80 per cent of strains of *Staph. aureus* belonged to one phage type (Type 71), most members of which inhibited the growth of corynebacteria and were resistant to penicillin[1]. More than 95 per cent of the Type 71 strains also produced opacity zones on serum agar plates.

The production of opacity on serum media by *Staph. aureus* has been little investigated, though its occurrence was noted by Woods and Parkin[2]. The zone of opacity extends for 1·0–1·5 mm. beyond the growth and is best seen after 15–18 hr. incubation aerobically at 37° C. The reaction is best demonstrated on infusion broth agar containing 5 per cent fresh horse serum. Substantially the same results are obtained with human serum ; but reactions with rabbit serum are rather less frequent and intense. No opacity occurs when the plates are incubated anaerobically or when the infusion agar base is replaced by 'Lemco' broth agar or by 'Oxoid' nutrient agar.

The ability to produce opacity is unevenly distributed among *Staph. aureus* strains. It occurs commonly only among two sorts : Type 71 strains from skin infections and penicillin-resistant Group III strains[3] from superficial infections acquired in hospital. Also, it is remarkable that strains producing opacity on serum agar are most uniformly negative to the egg-yolk reaction of Gillespie and

Alder[4]. Of 908 strains, from a variety of sources, 332 gave a positive serum opacity reaction and 498 were egg-yolk positive, but only two were positive to both tests.

Production of Gliotoxin in Soils

Since the majority of micro-organisms which are known to produce antibiotics are soil inhabitants, there has been considerable speculation whether they can produce these antibiotics in their natural environment. It is now generally accepted that if antibiotics are produced in the soil, this would probably occur in localized micro-environments where there is a favourable food supply, such as around particles of plant debris or in the rhizospheres of certain plants.

So far no one has reported success in demonstrating the production of an antibiotic in normal soil; but it has been shown that some soils, when enriched with organic matter and inoculated with an organism known to produce an antibiotic, will support production of an active substance[1,2]. I have shown[2] that gliotoxin can be produced in soil supplemented with plant material and inoculated with *Trichoderma viride*.

To determine whether antibiotic production is localized in the vicinity of plant debris, pieces of wheat straw (1 in. long) were introduced into an acid podsol from Wareham Heath inoculated with a spore suspension of *T. viride*. After seven days the straws and the soil surrounding the straws were each separately extracted with ether and the extracts tested for antibiotic activity. An active substance was present and was identified as gliotoxin by paper chromatography. The amount of gliotoxin present could be estimated roughly from the size of an inhibition zone produced on agar seeded with *B. subtilis*.

Straws from inoculated soil were covered with a good growth of *T. viride* and produced approximately 1 μgm. gliotoxin/straw, whereas those from uninoculated soil produced no activity. The inoculated soil immediately surrounding the straws yielded approximately 1 μgm. gliotoxin/gm. soil. This is a much lower yield than that from an equivalent weight of straw (13 μgm. gliotoxin/gm. straw). It would seem that either the gliotoxin was produced only in the straws and then began to diffuse out into the soil, or that the fungus, using the straw as a food base, grew out into the soil and produced some gliotoxin there. No gliotoxin was produced in straws buried in a Kettering loam of pH 6·3 unless either the straws or the soil was first acidified.

During the course of an experiment in which mustard seeds were dusted with spores of *T. viride* in an effort to protect the seedlings against soil-borne diseases, it was noticed that in some cases the seedlings developed chlorotic patches on the cotyledons. As the damage was very similar to that produced on seedlings which had been grown in solutions of gliotoxin, it seemed possible that gliotoxin was produced around the seedling, probably in the seed coat. After the seeds had been dusted with spores of *T. viride* and grown in John Innes potting compost for seven days, the seed coats were removed and placed on agar plates seeded with *B. subtilis*. Zones of inhibition were produced around the coats which had been inoculated with *T. viride* spores but not around the uninoculated control coats. The seed coats were extracted with ether, and the active compound was shown to have R_F values identica with gliotoxin on paper chromatograms. It was estimated that approximately 0·25 μgm. gliotoxin was produced per seed coat. Pea seeds treated in the same way were found to produce 4 μgm. gliotoxin/seed coat.

When these experiments were repeated with a new batch of potting compost it was found that an antibiotic was also produced on uninoculated pea coats This active substance was both antibacterial and antifungal, and was found to have similar R_F values to gliotoxin in several solvent systems.

The fungus which was isolated from the pea coats grown in the new batch of potting compost was identified as *T. viride*, and was found to produce high yields of gliotoxin in Weindling medium. The *Trichoderma* was not a contaminant of the seed coat but was isolated repeatedly from the soil.

These experiments have shown that high concentrations of an antibiotic can be produced in and around particles of organic matter, such as pieces of straw and seed coats, buried in soil. In a batch of John Innes potting compost in which a gliotoxin-producing strain of *T. viride* formed part of the natural flora of the soil, the fungus grew on the seed coats and produced gliotoxin there. This is an example of antibiotic production in an uninoculated soil in the vicinity of a very natural organic supplement.

Lactophenol Preparations for Soil Nematodes

One of the essentials of a fluid preparation fo nematodes is that coverslip supports must be included in the drop of mounting medium to avoi distortion of the specimens. For this purpose Goodey recommends glass fibres arranged radially in the drop but as the fibres may be of varied and unknow diameter, it is difficult to judge the correct size o drop. If the drop is too large, the lactophenol flow on to the upper surface of the coverslip, and th ringing medium ('Zut' or lactophenol gum) will no seal the mount. If the drop is too small, air space are left near the edge of the coverslip and the ringin medium is drawn into them by capillarity.

This difficulty has been overcome by using length of 80/20 nickel–chromium resistance wire as coversl upports (Brightray 'C', H. Wiggin and Co., Ltd., Birmingham 6). This is manufactured to a tolerance f ± 2·6μ for the following diameters: 25μ (50 tandard wire gauge), 30μ (49 s.w.g.), 40μ (48 s.w.g.), nd 50μ (47 s.w.g.). As the diameter of the coverslip upport is both known and constant, the required drop size can be calculated and delivered on to the lide by a micropipette fitted with a 'Pumpett' ttachment. Wire of slightly greater diameter than that of the largest specimen is selected for each nount, and is cut in lengths approximately equal to ne-third of the coverslip diameter. The pieces of wire are arranged radially in the drop, the specimens re added, and a warm coverslip is lowered on to he preparation. With the correct drop size the actophenol fills exactly the space under the coverslip.

There has been no visible evidence of reaction etween the nickel–chromium wire and lactophenol n slides which have been left for six months. The method saves time, and because remounting is seldom ecessary, specimens are less likely to be lost or damaged.

Accelerated Storage Tests for Dehydrated Vegetables

WHEN dehydrated vegetables are stored at high temperatures (for example, in the tropics) they ventually become unacceptable, usually because of the development of brown pigments. Since many ifferent factors, not precisely controllable, affect the ate at which the brown discoloration develops, it is irtually impossible to predict the storage life of the ehydrated product. Examination of the behaviour f dehydrated vegetables held at 37° C. has been the sual way of studying the effects of variables on ropical' storage life; but such tests may be prolonged and delay research, while they are of little alue to a manufacturer or purchaser who may need nformation before dispatching or purchasing the naterial.

The rate of development of browning is directly elated to the temperature of storage between about 5° and 50° C.[1], and it has been suggested that the eactions involved in the development of the brown gments at temperatures between 25° and 70° C. are milar[2]. It seemed possible, therefore, that storage t temperatures higher than 37° C. might enable a rediction to be made, in a relatively short time, of he rate at which browning would occur at the latter emperature.

Tests carried out at 37°, 55° and 70° C., in which amples after reconstitution and cooking were judged y an experienced taste panel, showed that at 70° C. rowning was too rapid for accurate assessment, but hat for a number of dehydrated vegetables the rate browning at 55° C. was approximately thirty mes that at 37° C.; that is to say, storage for a rtain number of days at 55° C. and for the same umber of months at 37° C. caused similar degrees browning.

In subsequent tests on dehydrated potato, more ccurate methods of assessment were sought. The gment was, in all but the most severely browned amples, completely soluble in 66 per cent ethanol, and a value for the extent of browning could be obtained by measuring the optical density of the resulting extracts at 400 mμ in a spectrophotometer. For large numbers of samples, however, this method was too slow, and a quick method was devised, in which the samples under examination were compared visually with a set of colour standards.

The standards were prepared by 'kibbling' dehydrated potato strips in a hammer mill, and using the fraction retained by a 16-mesh sieve but passing a 6-mesh sieve. The kibbled material was packed in nitrogen in Kilner jars and held at 55° C. for varying periods. A range of colours was selected from the browned material so produced, and assigned marks from 1 to 8, 1 being excessively brown and 8 being completely free from browning. When not in use the standards were stored in the dark at − 5° C. The material under test was kibbled, packed in nitrogen in Kilner jars in the same manner as the standards, and put into storage at the desired temperature. At intervals the test material was compared with the standards and awarded marks accordingly.

To check the validity of this visual colour scoring, a number of samples were tested both in this way and by measuring the optical density of the 66 per cent ethanol extract. The results were in satisfactory agreement: calculation of the correlation coefficient showed $r = -0{\cdot}90$. Similarly, the visual test results and the scores for colour obtained by the taste panel were also closely correlated ($r = +0{\cdot}94$).

In two successive years, the visual method was used to test the earlier finding that the rate of browning in dehydrated potato at 55° C. was approximately thirty times that at 37° C. The marks for material stored for 2, 3, 4, 5 and 6 days at 55° C. were plotted on the horizontal axis (x) against marks given to a sample of the same material after 2, 3, 4, 5 and 6 months respectively at 37° C. (y). Fig. 1 shows the results for 1954: the correlation coefficient was $r = +0{\cdot}91$ and the line of best fit to the pairs of readings was $y = 0{\cdot}989x - 0{\cdot}013$. Generally similar

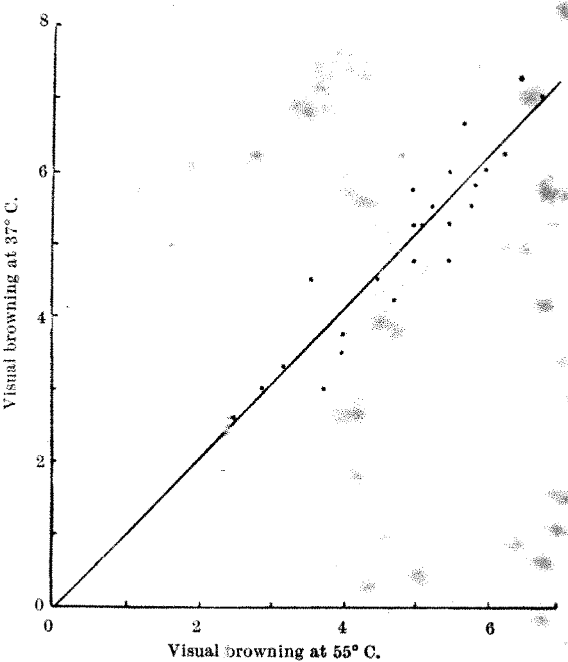

Fig. 1. Regression of visual browning after months at 37° C. upon visual browning mark after the same number of days at 55° C. (dehydrated potatoes, 1953–54). $y = 0{\cdot}989x - 0{\cdot}013$; $r = +0{\cdot}91$

results, though with somewhat wider scatter, were found in 1955 (correlation coefficient $r = +0{\cdot}81$ and line of best fit $y = 1{\cdot}028x - 0{\cdot}041$).

These results support the general thesis that the extent of browning developed in dehydrated potato during storage for a certain number of days at 55° C. is approximately the same as that developed during the same number of months at 37° C. It is evident that accelerated tests at 55° C. could be of value to both manufacturers and purchasers of dehydrated vegetables.

We are indebted to Mr. J. M. Harries for the statistical analyses.

Regeneration of Yeast Cells from Naked Protoplasts

OBSERVATIONS of the ability of cell fragments to re-form into new cells are very old[1]. Many experiments have been carried out on Protozoa and Algae especially, and importance of the nucleus for regeneration has been ascertained.

In our experiments we have investigated the power of regeneration in cell fragments of yeasts (*Saccharomyces cerevisiae*). The fragments were obtained in two ways: (1) By mechanical pressure on yeast cells the plasma flows out and takes up the form of droplets (Fig. 1), producing a large number of plasma droplets, but only one of which contains the whole nucleus; some physical properties of plasma can easily be studied with these plasma droplets[2]. (2) Under certain conditions, lysis of cell membranes in the surface layer of the autolytic yeast culture takes place. The protoplast becomes loose and breaks into several droplets. A very similar process in bacteria was described by Weibull[3], who has deprived the bacterial cell of a membrane by means of lysozyme. In our experiments we did not succeed in demonstrating the free hemicellulases and we presume that the yeast membrane is lysed by ferments which are closely bound to the protoplast.

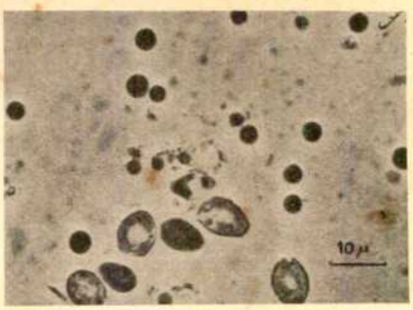

Fig. 1. Droplets of free plasma obtained by mechanical pressure on yeast cells. Phase-contrast. × 750

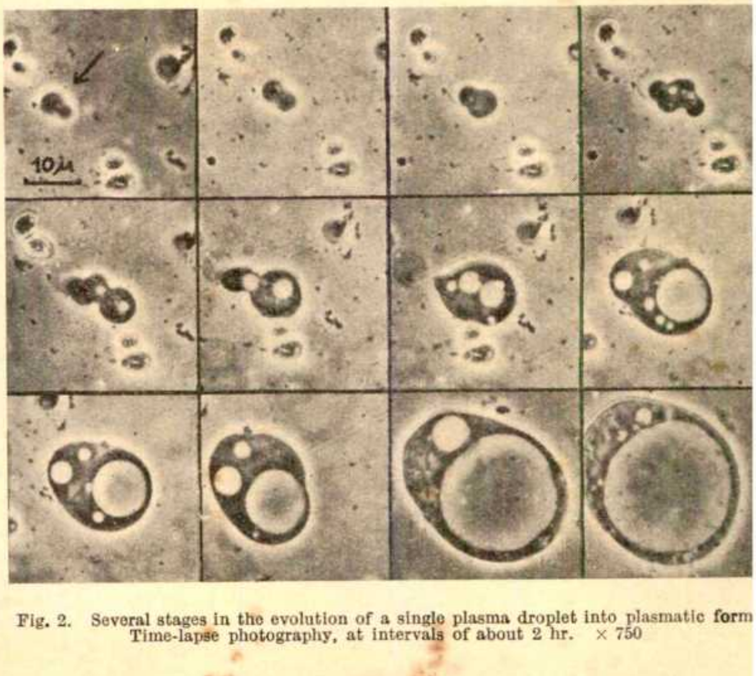

Fig. 2. Several stages in the evolution of a single plasma droplet into plasmatic form Time-lapse photography, at intervals of about 2 hr. × 750

Plasma droplets thus obtained can be transferred to nutrient media, though they are very fragile, and their further behaviour observed. We have transferred the droplets on agar with synthetic nutrient medium containing asparagine. Most of the plasma droplets die off in a few days, especially those obtained by the mechanical method. Others grow intensively for several hours. Growth is rapid and large plasma formations arise out of plasma droplets during 24 hr. (Figs. 2 and 3). The volume of plasma formations is ordinarily a thousand times bigger than the volume of a single yeast cell; they have no membrane and therefore an irregular outline. Th plasma is homogeneous, with many vacuoles. Plasm formations are often broken up, and the separate parts go on growing independently. I have show elsewhere[4] that the growth is not dependent o physical changes only of the plasma droplets, bu that there is real growth connected with quantitativ increase of plasma. In another investigation[5] it wa demonstrated that only the plasma droplets contai ing the nucleus develop; those without it die of In the later stages of development the plasma forma tions always contain more nuclei, which are structu ally rather different from the nucleus of the norm yeast cell. Neither Weibull[3] nor others[6,7] observe similar growth and the division of protoplasts aft lysozyme lysis of bacterial membrane, though prot plasts invariably remain alive, as is obvious fro their metabolism[6] and ability to form the bacteri phage[7,8].

Some of the plasma formations developed d generate after a few days without having change essentially; but others display further developmen changes. The plasma contracts, vacuoles disappea the plasma viscosity increases and there develo dense spherical formations, often of a large si (30–40µ). They, too, contain a greater number nuclei which are exactly like normal nuclei. If w

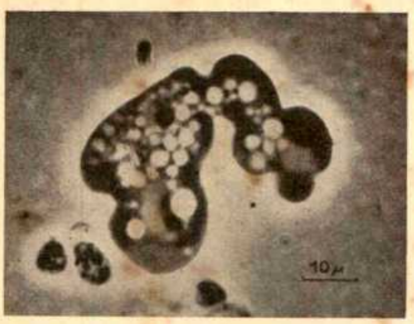

Fig. 3. A large plasma formation developed by growth from a plasma droplet. Phase-contrast. × 750

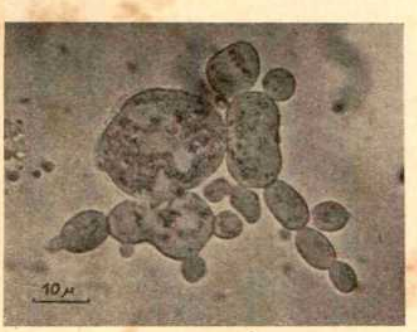

Fig. 4. Regeneration of new cells from a dense plasma formation. × 750

ransfer these dense plasma formations to a new
utrient medium, we find that a membrane develops
n their surface and that germination occurs in three
ays (Fig. 4). Cells result from this germination.
'he first generation looks very little like yeasts; but
ı later generations cells arise which correspond to
ıe yeast cell in size and form. The yeasts originating
ı this way can easily be isolated from the medium
nd cultivated by a technique customary for fer-
ıenting organisms. All changes described have been
ecorded several times on microfilm by time-lapse
hotography, so that there can be no doubt about
ıe right order of the separate evolutionary phases.

The majority of yeast strains developed by re-
eneration and isolated bear a morphological re-
emblance to the starting culture. Other strains
ere morphologically different and some of them
ave kept these deviations permanently. Among the
tter is one with permanently polynuclear cells.
mong the yeast strains obtained by regeneration,
ıere are considerable variations (in comparison with
ıe original strain) in biochemical properties,
specially in the speed of fermentation and production
f alcohol.

These observations show that cell fragments can
generate new cells even among Ascomycetes. The
ıode of regeneration described here differs a great
eal from those known hitherto; for (Fig. 5) the
rge amorphous and polynuclear plasma formations arise from the cell fragments before regeneration of yeast cells occurs.

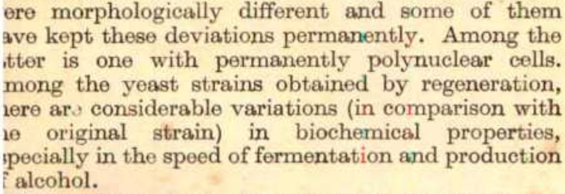

Fig. 5. Scheme of the course of regeneration: plasma droplet, vacuolized plasmatic formation, dense plasma formation and regeneration proper

Meloidogyne acronea, a New Species of Root-Knot Nematode

PLANTS of *Sorghum vulgare*, variety Radar (a variety of sorghum developed in South Africa), were collected on a farm in the Vryburg District, Cape Province. The land had for a number of years previously been planted only to maize and sorghum. The roots of the plants collected were found to be galled, the galling being caused by a root-knot nematode the morphology and pathological behaviour of which reveal it to be a new species. The name *Meloidogyne acronea* is proposed for this species.

Measurements, which in all cases were of fixed specimens, were as follows:

Adult female: length, 840μ–950μ; width, 400μ–600μ; length of stylet, 11μ–13μ; basal bulbs of stylet, width, 4μ, length, 2μ. The dorsal gland aperture is 4μ from the base of the stylet. The excretory pore opens anterior to the median œsophageal bulb, usually about fourteen annules from the lip region.

Infective larva: length, 440μ–460μ, width, 14·6μ; $a = 32$, $b = 5{\cdot}8$, $c = 9{\cdot}2$; length of stylet, 10μ; basal bulbs, width, 2μ, length, 1μ; dorsal gland aperture, 3μ from base of stylet.

Adult male: length, from 1·66 mm.; width, 0·04 mm.; $a = 38$, $b = 16$; length of spear, 16μ–18μ; basal bulbs, width, 4μ–5μ, length, 2μ; spicules (measured on chord of their arc), 32μ–34μ.

Eggs: length, 90μ–96μ, width, 44μ–64μ.

Meloidogyne acronea n.sp. differs from the type species *M. exigua*, *M. javanica*, *M. incognita*, *M. arenaria* and *M. hapla*, described by Chitwood[1], in the following particulars:

The posterior portion of the body of the female is drawn out into a distinct rounded protuberance on which are situated vulva and anus. The perineal pattern formed by the transverse annulation is extremely obscure. The cuticle is tougher. The mature female does not invariably remain embedded in the tissues of the host but often bursts out, the egg sac being lost in the surrounding soil. In both male and female, although the basal framework supporting the head does not appear to be as heavily sclerotized, the stylet appears slightly more robust. The tip of the tail of the larva is more rounded. The phasmids in the male are post-anal.

A large number of eggs was produced (approximately 1,000) by females parasitizing sorghum and laid in a gelatinous matrix.

The lip region in both larva and male is without cross-striations.

The development of the immature infective life-stages appeared to be similar to that of other species. *M. acronea* was successfully transferred to beans and tomatoes, on which reproduction took place.

Effects of Climate on Body Temperature and Respiration-rate of Buffaloes and Friesian Cattle

Observations were made on rectal temperature and respiration-rate of five groups of animals all kept in open sheds on the University Farm, Alexandria. Group I consisted of two buffalo cows and group II consisted of two Friesian cows, and all were in the same early stage of first lactation. The other three groups included two male calves each, from buffaloes, Friesians and native cattle. Readings of rectal temperature and respiration-rate were taken three times daily at 8.30, 11.30 a.m. and 2.30 p.m. on quietly standing animals on two days weekly for seven weeks from July 23 until September 9, 1955. Air temperature was recorded at the same intervals and ranged between 37·2° and 38·9° C.

There was a highly significant difference in body temperature and respiration-rate on different days and throughout the day due to different weather conditions between and during days. From Table 1 it will be seen that the mean body temperature and respiration-rate of the buffaloes was lower than those of the Friesians and the native cattle; the nativ calves, however, showed lower values than those c Friesian calves. The differences between all thes results were highly significant.

Table 1

Comparison	Mean rectal temperature (° C.)	*s.e.*	*d*	Mean respiration-rate/min.	*s.e.*	*d*
Buffalo cows	38·39	0·038	−0·25	25·08	0·388	−7·68
Friesian cows	38·64	0·040		32·76	1·026	
Buffalo calves	38·34	0·027	−0·32	21·30	0·442	−8·96
Friesian calves	38·66	0·036		30·26	0·706	
Buffalo calves	38·34	0·027	−0·17	21·30	0·442	−4·56
Native calves	38·51	0·025		25·86	0·498	
Native calves	38·51	0·025	−0·15	25·86	0·498	−4·40
Friesian calves	38·66	0·036		30·26	0·706	

s.e., standard error; *d*, difference. All differences are significant at the 1 per cent level.

In buffaloes, the correlation coefficient betwee the average daily body temperature and air tem perature for eight individuals was $r = + 0·10$ an non-significant. A similar estimate obtained for th respiration-rate and air temperature was $r = + 0·2$ and highly significant. However, the correlatio between body temperature and respiration-rate wa $r = + 0·20$, and this was statistically significant.

For the successive days, the repeatability betwee readings for respiration-rate of the buffalo stock wa found to be 36 per cent. Regarding body temperatur buffaloes did not tend to follow any particular patter in this respect.

Scent of Otariids

Some years ago I was engaged in an examinatio of the small, almost residual, herd of fur sea (*Arctocephalus australis*) in the Falkland Islands. I the course of it a number of animals were kille among them several bulls, or 'wigs' in the sealer' vocabulary. After handling the bulls' skins ther was left on the unwashed hands a general, no unpleasant, 'seal' smell; but after washing ther remained a definite perfume rather resembling th odour emitted by the common civet when it i pleasurably excited. On one bright, sunny da therefore somewhat warm on the rocks, I passed few feet away from and to leeward of a bull and was able to observe the pleasant perfume, whic was definitely air-borne. If I remember rightly, th seal was a little angry. The seals on which thes observations were made were all met with in summe that is, over the rather extended breeding seaso

At various times I have handled fresh skins of th adult male of the southern sea lion (*Otaria byroni* and on them I have observed a rather stronger an ranker odour which was undoubtedly that of th animals themselves, not of the generally insanitar terrain. This scent contained a suggestion of swee ness in it.

It seems possible that a distinctive odour produce by the adult males of the Otariidae, a family i which the bull occupies territory and waits for cow to come ashore, may be of value to the species as direction indicator to the cows. We cannot estima the distance at which the odour could be observe by the animals—it may be greater than we think.

It would be interesting to know if other worke on the mammals have made observations on scen characteristic, specifically or otherwise, of the su jects. Some of us, at least, have been from childhoo familiar with the 'smell of mice'.

British Society for the History of Science, Philosophy of ience Group (in the Joint Staff Common Room, University College, wer Street, London, W.C 1), at 5.30 p m.—Mr. A. G. N Weddell: roblems of Cutaneous Sensation".

University of London (in the Anatomy Theatre, University llege, Gower Street, London, W.C.1), at 5.30 p m —Prof F. S. denheimer (Jerusalem): "The Growth of Knowledge of Animals Palestine from Palæolithic Times".* (Further Lectures on May 16 d 17.)

Institution of Electrical Engineers, Education Discussion rcle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on n Elementary Presentation of the Principles of Magnetism and ectromagnetic Induction, with Demonstrations". Opening Speaker: of. K. A. Hayes

Royal Society of Arts (at John Adam Street, Adelphi, London, .C 2), at 6 p m.—Prof. David V. Glass: "Some Aspects of the velopment of Demography". (Second of three Cantor Lectures on ecent Studies of Sociology")

Institute of Metal Finishing (at the Northampton Polytechnic, . John Street, London, E C 1), at 6.15 p.m.—Mr. C. H. Rumble: he Processing of Gramophone Matrices".

Monday, May 14—Thursday, May 17

Physical Society (in the Royal Horticultural Society's Old and w Halls, Westminster, London, S.W.1)—40th (1956) Annual hibition of Scientific Instruments and Apparatus.

Discourses and Demonstration Lectures.

nday, May 14

At 6.15 p.m.—Mr. H. G. Jenkins: "Recent Developments in Light urces".

esday, May 15

At 6.15 p.m.—Prof. H. Lipson: "The Production of Images of emical Molecules".

ednesday, May 16

At 6.15 p.m.—Mr. G. G. Gouriet: "Colour Television—Considera- ns which have led to Recent Trends".

Tuesday, May 15

Wright-Fleming Institute of Microbiology (at St. Mary's spital Medical School, London, W 2), at 5 p.m —Dr. W. E van yningen: "Recent Trends in Research on Bacterial Toxins"* mroth Wright Lecture).

ron and Steel Institute (at the Royal Institution, Albemarle eet, London, W.1), at 6 30 p.m.—Mr. James Mitchell: Bessemer tenary Lecture.

Royal Aeronautical Society (at 4 Hamilton Place, London,), at 7 p.m.—Dr. A. Buchanan Barbour: "Medical Aspects of ght Comfort and Efficiency".

niversity of London (at the Institute of Archæology, Inner le, Regent's Park, London, N.W.1), at 8 15 p.m.—Prof. V. G. lde: "The Primary Spread of Neolithic Farmers in Temperate ope"* (Third of seven lectures on "The Dawn of European ilization—Thirty Years After". Further Lectures on May 22, 29, e 5 and 12)

Wednesday, May 16

oyal Society of Arts (at John Adam Street, Adelphi, London, .2), at 2.30 p.m —Commander C. G. Mayer, U.S.N.R.: "Electronic tography" (Peter Le Neve Foster Lecture).

eological Society of London (at Burlington House, Piccadilly, don, W.1), at 5 p.m.—Mr. R. W. R. Rutland: "Structure, Meta- phism and Granite Emplacement in the Sokunvatn Area of thern Norway"; Dr W. J. Phillips: "The Criffel-Dalbeattie nodiorite Complex" (to be read by Prof. A Wood).

nstitute of Navigation (at the Royal Geographical Society, ensington Gore, London, S.W.7), at 5 p.m.—Mr. G. P. B. Naish: e James Cook Exhibition at Greenwich"; Mr. C. H Gibbs-Smith, D. N. Harrison and Mr. C. S Durst: "Ballooning".

oyal Meteorological Society (at 49 Cromwell Road, London, .7), at 5 p.m.—Scientific Papers.

oyal Society of Medicine, Comparative Medicine Section 1 Wimpole Street, London, W.1), at 5 p.m.—Annual General ting; followed by a Discussion on "Learning in Man and Animals".

oyal Statistical Society (at the London School of Hygiene and ical Medicine, Keppel Street, London, W.C.1), at 5.15 p m.— Dorothy Cole and Mr J. E. G. Utting: "Estimating Expenditure, ng and Income from Household Budgets".

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W C.1), at 5.30 p m.—Dr K. W. Keohane and Dr. W. K. Metcalf: "Microspectrophotometry of Hæmoglobin Using the Burch Microscope".

Wednesday, May 16—Thursday, May 17

Iron and Steel Institute (at the Royal Institution, Albemarle Street, London, W.1, and at 4 Grosvenor Square, London, S.W.1)—Eighty-Seventh Annual General Meeting.

Wednesday, May 16

(At the Royal Institution). At 11.45 a.m.—Prof. N. F. Mott, F.R S: Ninth Hatfield Memorial Lecture.

Thursday, May 17

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 4 p.m — Annual General Meeting. 5.15 p.m.—Prof. C. W. Dannatt—Presidential Address.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. J. C. Swallow "Research in the Plastics Division of Imperial Chemical Industries Limited".

London Mathematical Society (at the University, Nottingham), at 5 p.m.—Dr. E. F Collingwood: "Cluster Sets and Prime Ends".

Royal Aeronautical Society (at the Royal Institution, Albemarle Street, London, W.1), at 6 p.m.—Sir William Farren, F.R.S.: "The Aerodynamic Art" (44th Wilbur Wright Lecture).

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p m —Dr. B. B. Waddy: "Organization and Work of the Gold Coast Medical Field Units".

Friday, May 18

British Psychological Society, Industrial Section (in Room 425, Birkbeck College, Malet Street, London, W.C.1), at 1 p m.—Mr. R. N. Tronchin-James: "The Personality Structure of Senior Industrial Executives"; Mr. V. W. Wilson: "Some Personality Characteristics of Industrial Executives".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Computer (with G.C.E. with mathematics at "A" level, or equivalent qualifications) in the Scientific Department in London, to work with scientists engaged on a variety of mathematical and statistical problems—National Coal Board, Staff Department, Hobart House, London, S.W.1, quoting SS/£65 (May 18).

Senior Lecturer in Production Engineering, and a Senior Lecturer in Applied Thermodynamics—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (May 18)

Lecturer or Assistant (Grade B) (with special qualifications in plant physiology) in Botany—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S W.3 (May 23).

Assistant Lecturer in Pure Mathematics—The Registrar, The University, Nottingham (May 26).

Lecturer or Assistant Lecturer in Zoology—The Secretary, Bedford College (University of London), Regent's Park, London, N W.1 (May 26).

Assistant Lecturer (with special qualifications in physical chemistry) in Chemistry—The Registrar, The University, Manchester (May 28)

Lecturer (with special experience in virus diseases) in Microbiology—The Secretary, The Queen's University, Belfast (May 30).

Lecturer (with research experience in aeronautics, preferably in the field of high speed aerodynamics) in Aeronautical Engineering—The Secretary, The Queen's University, Belfast (May 30).

Abstractor, Scientific Assistant grade (with a degree in agriculture or natural science, a knowledge of languages, and the ability to write clear concise English), for duties which mainly consist of abstracting world scientific literature on grassland and field crop research—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berks (May 31).

Assistant Lecturer in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (May 31)

Assistant Lecturer (with a good honours degree) in Pure Mathematics—The Registrar, King's College, Strand, London, W.C.2 (May 31)

Junior Lecturer (medically qualified graduate) in Pharmacology—The Dean, Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (May 31).

Lecturer in Pharmaceutics, and a Lecturer in Pharmaceutical Chemistry, at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C 1 (May 31).

Lecturer (with an honours degree in chemistry with considerable research experience and special interests in physical chemistry) in Physical Chemistry—The Registrar, College of Technology, Manchester 1 (June 1).

Physiologist or Biochemist (preferably honours science graduate with a knowledge of, or willingness to learn, foreign languages, especially German) to join a team on information work and abstracting—The Director, Commonwealth Bureau of Dairy Science, Shinfield, Reading (June 1)

Principal of the Wellington Technical College, New Zealand, to be in charge of a technical high school and a large number of day and evening technical classes, and act as Secretary to the Board of Managers—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (June 1).

Lecturer in Physiology at the University College of the West Indies—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (June 4).

Chair of Chemistry—The Registrar, University College, Singleton Park, Swansea (June 5).

Lecturer in Education at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 7).

Physicists and **Electrical Engineers** (with a first- or second-class honours degree or equivalent in physics or electrical engineering) at the Ministry of Supply Radar Research Establishment, Malvern, Worcs, for research and development work, mainly on radar and electronic equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.148/6A (June 8).

University Lecturer (with an honours degree in pure science with organic chemistry and biochemistry as principal subjects) **in Animal Nutrition**—The Secretary, School of Agriculture, Downing Street, Cambridge (June 8).

Lecturer or **Assistant Lecturer** (with special qualifications in organic chemistry) **in Chemistry**—The Registrar, The University, Manchester 13 (June 11).

Lecturer in Geology with responsibility for mineralogy and petrology to special degree standard, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 15).

Chair of Philosophy at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (June 23).

Lecturer or **Senior Lecturer** (with a university degree in civil and/or agricultural engineering, and some interest in structures and building planning) **in Agricultural Engineering** at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 30).

Senior Research Fellow (with experience in electronic physics) for the development, under the direction of Prof. G. Porter, of pulse and rapid recording techniques for the study of fast reactions—The Registrar, The University, Sheffield (June 30).

Research Students (with the degree of Bachelor or Master of a British university other than Manchester) **in Science**—The Registrar, The University, Manchester 13 (July 1).

Assistant Experimental Officer (graduate in chemistry or biology, or both) **in the Unit for the Study of Biochemical Problems in Relation to Fisheries**, for duties which will include the estimation of vitamins in, and histology and culture of, aquatic organisms—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 56/6

Entomological Field Officer (with Inter.B.Sc., and between the age of 24 and 45) **in the Medical Department**, Kenya Government, to perform laboratory duties and assist with entomological research (including safari work)—Crown Agents, 4 Millbank, London, S W 1, quoting M3A/43289/NF.

Laboratory Assistant for School Physics Laboratory—Mr. P. Bateman, Highgate School, London, N.6.

Lecturer or **Assistant Professor in the Department of Mathematics**, Joint Faculty of Arts and Science at Dalhousie and King's Universities—The Dean of Arts and Science, Dalhousie University, Halifax, Nova Scotia, Canada.

Mathematician (preferably with a knowledge of electronics) to assist in the operation and development of an electronic digital computer used in the Statistics Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Physical Chemist (graduate or equivalent), to take charge of the Polymer Characterization Section—The Director of Research, British Rubber Producers' Research Association, 48 Tewin Road, Welwyn Garden City, Herts.

Physicist in the Radiotherapy Department, to work with staff of the Department on a research programme on moving beam X-ray therapy dosage—Hospital Secretary, Royal Northern Hospital, Holloway Road, London, N.7.

Scientific Officer (Control) (with a good honours degree in either zoology, entomology, agricultural chemistry or physics or allied subjects) **in the International Red Locust Control Service**, Abercorn, Northern Rhodesia, to carry out operational research on the chemical control of red locusts in the outbreak areas in Tanganyika and Northern Rhodesia—The Crown Agents, 4 Millbank, London, S.W.1, quoting Ref. M3B/43298/TA.

Senior Laboratory Technician (with experience in laboratory management and glass-blowing) **in the Science Department**—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham.

Senior Technician (with experience in experimental physiology) **in Physiology**—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

Specialist (Chemist) (with at least a second-class honours degree in chemistry, preferably inorganic or physical chemistry, followed by one year's postgraduate training or approved experience in agricultural chemistry including statistical methods) **in the Department of Agriculture**, Gold Coast Local Civil Service, for duties which are concerned with the cultivation of cocoa and include planning and execution of research into soil fertility, field work in connexion with the use of inorganic manures, and the administration of staff, equipment and laboratory—Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/13/022.

Veterinary Bacteriologist (expert in the preparation of serums and vaccines) **in the Veterinary Laboratory** of the Directorate General of Veterinary Services, Iraq—The Ministry of Labour and National Service (A.S.12), Almack House, 26–28 King Street, London, S.W.1, quoting A.12/IRQ/162/ME

CHAPMAN & HALL

Ready 24 May

GASEOUS NEBULAE

by

L. H. Aller

(Professor of Astronomy, University of Michigan)

Size. 10 *in.* × $6\frac{1}{2}$ *in.* 322 *pages* *Illustrated* 63*s. net*

This is the third volume in the International Astrophysics Series. It is the first attempt in the English language to review this important branch of astrophysics for the benefit of astronomers, physicists and students. The extensive theoretical work in the field, which is scattered through many volumes of research journals, is here reviewed concisely and critically. Certain theoretical results, hitherto unpublished, are also included.

ECONOMIC GEOGRAPHY OF INDUSTRIAL MATERIALS

Edited by

Albert S. Carlson

(Professor of Geography, Dartmouth College, Hanover, N.H., U.S A.)

Size: $10\frac{1}{4}$ *in.* × 7 *in.* 494 *pages* *Illustrated* 100*s. net*

Twenty-seven experts in a wide range of key industries have contributed to this work, which provides the answers to a great many perplexing problems that industry must face in the ever-changing economic atmosphere of to-day.

37 ESSEX STREET, LONDON, W.C.2

PRECISION BS INSTRUMENTS

Model A Polarimeter on cast iron Optical Bench

Monochromator can be mounted, as illustrated, when desired.

Suitable for the insertion of auxiliary apparatus between polariser and analyser.

HIGHER TECHNICAL EDUCATION IN BRITAIN

THE debate on higher technical education on Tees-side, which Mr. H. A. Marquand initiated n the House of Commons on the adjournment on March 29, was not reassuring to those who believe that, in spite of the care taken in the White Paper to distinguish between technical and technological education, the proposal to raise to colleges of advanced technology of university standard some twenty-four or more of the existing technical colleges which receive 75 per cent grant for certain of their advanced work, is likely to spread available man-power and money too thinly. Mr. Marquand, in pressing the claims of the Tees-side area for a college of technology, challenged in the first instance the regional distribution. Eleven of the colleges it is proposed to advance are in the London area, and only five, apart from the Manchester College of Technology, which is not included in the count, are in the north of Engand. Mr. Marquand said quite rightly that a much arger proportion of the industry of Great Britain is to be found in the north than is suggested by these igures, and it is obviously wise, in planning the extension of technological and technical education, particularly with sandwich courses in mind, to pay a good deal of attention to the location of ndustry.

This applies particularly to technical education, and thus far the argument is sound. Mr. J. E. S. Simon, in supporting Mr. Marquand's argument for the development of Constantine College, Middlesbrough, as a regional college of technology for the Tees-side area, suggested that besides this question of balanced distribution, location should also be determined by the existence in the area of a tradition of craftsmanship, and the attitude of local authorities, employers and trade unions. These may well be more important than the last factor to which Mr. Simon referred, namely, the existence of an efficient technical college capable of expansion. The presence of such a college may well, as the debate showed, engender questions of local prestige and involve difficult decisions as to the location of technical and technological education, which are not always carried on with full efficiency in the same institution.

Mr. Arthur Palmer, member for Cleveland, also urged that chemical developments on Tees-side as well as the expansion of other industries, especially steelmaking, make a technological institution of the highest standard desirable on Tees-side; and Mr. David Jones, member for the Hartlepools, agreed that in the Constantine College, Middlesbrough, there is the makings of an institution well situated to meet the needs of the area. The Parliamentary Secretary to the Ministry of Education, Mr. D. Vosper, in replying for the Government, agreed that such considerations should be taken into account and, more specifically, said that the Minister would bear in mind the large developments on Tees-side when deciding which additional colleges should be recognized as colleges of advanced technology. Mr. Vosper reiterated that other colleges besides those named in the White Paper might qualify for the 75 per cent grant, and he explained at some length why the Constantine College had not been named in the White Paper.

Much more important, however, was Mr. Vosper's indication that the White Paper on Technical Education is to be debated in full, when the Minister hopes to elaborate the position of the colleges of advanced technology, and his admission that we must ensure that our limited resources are not spread too thinly. In this welcome admission, Mr. Vosper had particularly in mind the teaching staff, and it is something that the Government should at last recognize that the supply of qualified teachers for advanced work is limited and must therefore be used to the best advantage by building up units of reasonable size. We must not try to provide too many or too varied courses in any particular place.

That, of course, is the real indictment of the Government's proposals as set out in the White Paper, coupled with anomalies such as the treatment of the College of Technology, Manchester, the Imperial College of Science and Technology, and the Royal Technical College, Glasgow, separately from other technological institutions. If the resources for technological education in Britain are to be deployed to the best advantage, they must be planned as a whole, whether training is given in a university department or in a college of technology. The responsibility must be placed fairly and squarely on some one authority, and if this cannot be borne by the University Grants Committee, an appropriate body must be created for the purpose.

Mr. Vosper's reply on March 29 indicates how far the Government has yet to go in facing the realities of the situation; nor did Mr. Vosper give any indication that the Minister of Education is likely to grapple with the problems that parochial rivalries will engender for an adequate regional plan for not more than a dozen colleges of technology where higher technological education is given under appropriate conditions of teaching and research. Those issues cannot be avoided, and the earlier they are faced and tackled the more likely we are to secure the understanding, goodwill and co-operation which have marked the relinquishing of local control over the College of Technology in Manchester. Moreover, if the issue is grasped with imagination and the expansion of technical education is tackled with the energy and understanding as well as on the scale it demands, there should be little chance of any local dissatisfaction that a particular technical college has not been raised to a college of technology.

It should be emphasized, in fact, that the difference between a college of technology and a technical college, between technologist and technician, is qualitative, and not one of social status. We need many more technicians than technologists; but their work is just as important and satisfying, and the idea of inferiority should be attacked wherever it displays itself. It is the difference in the nature of the instruction to be given and the conditions required that make it difficult for justice to be done to both types of training within the same institution. It is to be hoped that the forthcoming debate will force the Government to declare itself much more fully about its proposals for the expansion of technical education, that is, the training of technicians, than it has done in the White Paper.

It would appear improbable that in the forthcoming debate the plans of the universities over the next quinquennium for technological education will be made known; and until those plans are revealed, the adequacy of the Government's proposals for the expansion of technological education cannot be assessed. What needs to be emphasized now is that we are most likely to develop the resources of Britain to the best advantage if technological education, if not technical education also, is placed under the responsibility of one body of the standing of the University Grants Committee. Not only Dr. Venables in his recent book, but also Lord Waverley, at the annual luncheon of the Parliamentary and Scientific Committee on February 27, and others, have strongly pressed this view.

Financing the colleges of technology on a basis similar to that established under the University Grants Committee would give the colleges the status and independence which would help to attract staff of the highest ability; and the principle of quinquennial grants would greatly facilitate the undertaking of research on an adequate scale. Even more important, the standing of such a body would give its recommendations on technical education as well as technological education an authority which the Minister of Education could not ignore, and which should strengthen his hand in dealing with those authorities who, for any reason, were unwilling or unable to co-operate or maintain the standards which the national interest indicates. Technical and technological education cannot be sharply separated; but a body of this character would be well placed to indicate ways and means which would avoid placing on local authorities responsibilities they should not fairly be expected to meet from local funds.

While, however, the Government hesitates and, lacking the courage to deal with the real difficulty, has called into being what Dr. D. S. Anderson terms an entirely unnecessary body in the National Council for Awards in Technology, there is a remarkable unanimity of opinion among those best qualified to judge the needs of both technological and technical education in Britain. Dr. Anderson, addressing the Northern Counties Technical Examinations Council on February 14, emphasized the importance of sandwich courses. Like Dr. Venables, he believes these will be the major development of the next decade; but, unlike the White Paper, he detailed the conditions which should be met before an institution can efficiently participate in such schemes. These conditions would limit potential ultimate expansion to some twenty institutions at most, if the scheme was to lead to an award recognized as at least equivalent to a university degree. Moreover, Dr. Anderson pointed to the value of the co-operation to be obtained from the professional institutions, which the Government has ignored, as well as to the importance of greater co-operation with industry; and he stressed particularly the possibilities of making greater use of the staffs of technical colleges for consulting work and also the importance of making opportunities, by shorter sessions and a longer summer vacation, to keep up to date and maintain closer contact with industry.

These are not simple problems; but they should not be ignored and left unsolved as the Government proposes. Moreover, the release of teachers to return to industry and be brought up to date in the latest manufacturing technique is related to such problems as the education of older engineers which was discussed last January at a joint meeting of the Institutions of Civil, Mechanical and Electrical Engineers. Since the Second World War, the number of postgraduate courses available not only for engineers, but also for chemists, physicists and others, has greatly increased, and they are probably provided by most universities and colleges of technology in Britain. It does not appear, however, from either the papers presented or the subsequent discussion, that we have yet learned the best ways of presenting such courses, or are able to assess the real value of such short courses compared with the university or technological course of, say, six months duration. Nor is it clear where such courses are best organized.

The answers to such problems involve questions about the release of staff on both sides, or even its transfer from industry to the colleges of technology or vice versa, and much more critical and constructive thinking must be given to them if the essential co-operation from industry is to be secured. The point to be emphasized here is that the conditions created in both colleges of technology and the technical colleges by the proposed expansion should be such as to facilitate these developments and make the interchange and release of staff easier and no more difficult. Nor is it simply that postgraduate courses are designed to provide industry's leavening of men capable of technical leadership and really advanced thinking with the opportunities of advanced theoretical study they require. They are also part of the means of disseminating rapidly throughout industry knowledge of the latest techniques of design and knowledge.

In this sense both technical colleges and colleges of technology in Britain must form part, if not the nucleus, of a public technical information service. They cannot, however, add this to their primary function of teaching, if not of research, unless they are adequately equipped. The plain truth is that, as was pointed out in a memorandum recently prepared by the Library Association to the Scientific and Technical Information Committee of the Advisory Council on Scientific Policy, and is amply confirmed by the returns from the University Grants Com ttee, there is scarcely a major technological institution in Britain that is at present adequately equipped to render the library service alone that its wn staff and students need. Standards not merely f equipment and in the provision of space for readers ut also of expenditure on books and periodicals need o be expanded, quite apart from any prospective crease in the present number of students, before the olleges of technology or technical colleges can hope o make any useful contribution to the regional echnical library and information service that dmittedly is required to further the more effective tilization of existing knowledge.

This is only one respect in which the Government's resent proposals are unrealistic and appear to pay nsufficient attention to what needs to be done to aise the standards of even a dozen institutions in ritain to enable them to give efficient regional ervice in respect of teaching, research and the dis-emination of information. There are other respects n which more could be done to eliminate waste and ecure the full use of existing facilities. Nothing that e Prime Minister said to the Parliamentary and cientific Committee on February 29 removed such isgivings. Sir Anthony Eden repeated that it is the tention to increase the output of 'technologists' om some twenty or more technical colleges by fifty er cent, and that these colleges must have a high atus and be as independent as possible. He did not dicate, however, where the necessary qualified staff to be obtained; nor did he enlarge on the plans expand the output of technicians and craftsmen om the other technical colleges. Until such plans e indicated more precisely, it is probable that the ore nearly the Government's proposals to produce nother 2,500 technologists a year succeed, the more rious will be the effect on the output of supporting chnicians and craftsmen.

There are thus numerous points on which the overnment should be pressed to elaborate its plans nd to modify the proposals set forth in the White aper. But there are some hopeful features of the tuation. The Industrial Fund for the Advancement f Scientific Education in Schools, already within ght of its financial target of £3·5 million, should ntribute to encourage more boys and girls to take p careers in science, provided that full use is ade of the new special responsibility allowances nd other measures to deal with the shortage of ience masters. The scholarship scheme recently ndowed by Imperial Chemical Industries to enable hool children who have taken arts subjects at hool to enter the universities to train as scientists ould, like the scheme announced last year for the niversity of Liverpool, and the preliminary science ourse at the Imperial College of Science and Tech-ology, enable more school leavers to transfer from rts to science. Among the best proposals in the hite Paper are those which will permit State holarships to be held for courses leading to awards technology. There is still room, however, for other niversities and for local education authorities to romote these trends by their own action, and it hould be borne in mind that a similar scheme at University College, Oxford, met with so disappointing a response that no award could be made.

Moreover, at the other end, to which also Dr. Anderson referred, the concern of technical colleges with training for management is checking excessive specialization and encouraging the broad education, stressed alike in the White Paper and more recently at the Conference of the British Institute of Management and the Institute of Industrial Administration at Southport during March 20–21. We need, as Mr. D. R. O. Thomas urged there, men who can evaluate the significance of technology and science, who are responsive to ideas over a wide front and are capable of accepting responsibility and acting with courage and decision. We need also technicians and craftsmen who appreciate the significance of change and are ready, as well as competent, to adopt new techniques and products; and it should be noted that at the annual conference of the National Association for the Advancement of Education for Commerce, Mr. J. P. Jones's plea for liberal studies in technical courses found general support.

Perhaps the best feature of the discussion now proceeding on the expansion of technical and technological education in Britain is that it contributes to a fuller public understanding of all that is involved. Such understanding is essential if we are to secure for the technical college the amenities which Dr. Anderson rightly stressed as indispensable to enable it to fulfil its real function. It is equally essential in order to ensure that the expansion of technological education is carried out not as something apart, but as one element in the development of the whole education system of Britain, to equip the youth of the nation to play its fitting part in the age of nuclear energy, of the automatic factory and of other rapid technical changes on which the world is entering. That at least is what is implied in any action to give effect to recommendations which may come in due course from the Crowther Committee set up on March 2.

BIOCHEMICAL GENETICS

Genetics and Metabolism

By Robert P. Wagner and Herschel K. Mitchell. Pp. xi+444. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 60*s*. net.

It is probable that within the next generation the science of genetics may split. If so, one branch will perhaps unite with biochemistry. It will be concerned with processes which are understood at the molecular level. For example, what is now called crossing-over will probably be called transphosphorylation in nucleic acid chain molecules, and what is now called mutation will turn out to consist of several rather disparate processes. Another section will deal with developmental processes not yet reduced to biochemistry, and a third with the genetics of populations.

The book under review can be thought of as a pioneer exposition of the unified sciences of biochemical genetics and dynamical biochemistry. The authors are best known for their work on *Neurospora*, and Chapters 5 and 8, which are mainly concerned with this fungus, are particularly good. The book can be read by a student who does not know very much biochemistry or genetics; for it attempts to describe cellular structure, and the nature of enzymes and genes, and ends up with the discussion of a number of developmental questions, including the very fundamental one of 'self-duplicating' units outside the nucleus. Were it not for its price, I should recommend it to every student of biology.

It is so good that I have little doubt that a new edition will soon be needed, and it is therefore constructive to point out what seem to me to be defects in it. The discovery of the yellow anthochlor pigments derived from benzalcoumarone by Geissmann and his colleagues should have been included in Chapter 4, much of which was out of date when written. The treatment of human genetics is inadequate, particularly as this branch of genetics furnishes so many striking examples of conditions due to the absence of a specific enzyme, such as acatalasæmia, phenylketonuria and, more recently, galactosæmia. Again, human blood may fail to coagulate owing to the lack of any of six different proteins, each of the syntheses of which is controlled by a different gene. Most of them do not seem to be enzymes, in the ordinary sense of that word, and they are perhaps a model for systems which will later be discovered within cells. The account of the metabolism of homogentisate refers to no work since 1914, nor does that of the blood group antigens describe the work either of Morgan and his colleagues, or of Kabat and his colleagues, on their composition.

As I know to my cost, the compilation of a book on this subject involves very wide reading of periodicals, and the above criticisms are made in sympathy rather than malice. To sum up, the book was badly needed, and I hope that it will be widely read. But just because it is a pioneering effort, it lacks some of the balance and completeness which are to be expected in texts on a topic that has been systematically taught for some decades.

J. B. S. HALDANE

A NEW SYNTHESIS OF SPECIAL RELATIVITY

Relativity

The Special Theory. By Prof. J. L. Synge. (Series in Physics.) Pp. xiv+450. (Amsterdam: North-Holland Publishing Company, 1956.) 38 florins; 76*s*.

THIS notable book was originally planned to cover both the special and the general theories of relativity, but the special theory developed in such a way that, in the end, the general theory had to be omitted. The evident enjoyment with which it was written conveys itself to the reader, and even the sections dealing with the more classical parts of relativity show something of the excitement of fresh discovery. The book represents a breakaway from traditional modes of presentation. Here are no trains, or embankments, or lightning-flashes striking rails, or even the Michelson–Morley experiment except as an incidental. Neither is there a formal series of postulates and theorems designed to display logical self-consistency. Hypotheses are clearly stated as the need for them arises, and points of logical, physical or philosophical difficulty are never shirke self-consistency thereby being made apparent wit out fuss. Prof. J. L. Synge, remarking that the pu pose of a mathematical model is to assist in th exploration of Nature, expresses the opinion that " theory in mathematical physics is to be judge primarily on the basis of its logical consistency an only secondarily on the basis of the truth of it physical predictions", both Newtonian and relativisti mechanics being thus unassailable as mathematic models. With that doctrine one may well agre provided a given model does, in fact, fulfil the state purpose.

The basic plan of the book is to utilize fou dimensional geometrical ideas to the full, whil keeping their physical meaning and descriptio always in mind. The essential properties of Minkowskian four-space in relation to physical concepts ar established in the first three chapters with a clarit characteristic of the author. This is followed by full and fresh account of the Lorentz transformatio and its physical significance. Here and afterward the switch from the geometrical to the physica description, and vice versa, is constantly an illuminatingly made. A consequence is that, for all it comprehensiveness, the book is perhaps more suite to mature readers than to beginners in this field.

Nothing much short of a page-by-page account the author's arguments, methods and results coul do full justice to an interesting and lively book After a chapter on the mechanics of a particle including collision and disintegration problems, h proceeds to the mechanics of a discrete system. Here in order to obviate the difficulty caused by the absenc in relativity of a law of action and reaction excep for particles in direct contact, he uses his ow tentative theory of "internal impulses", these bein hypothetical entities, possessing energy and momentum, which the physical particles of the system ar supposed to fire at one another. Applied to tw particles only, with a single internal impulse shuttlin between them, the inverse-square law emerges as first approximation when the relative speeds of th particles are small compared with that of light. Thi remarkable deduction of the inverse-square law ma cause the reader to raise an admiring or a sceptica eyebrow according to his prejudices. Prof. Syng himself expresses no more than interest coupled wit a doubt about the general validity of his scheme fo physics as a whole.

From the mechanics of a discrete system he passe to that of a continuum by using statistical method This leads to the introduction of the energy tenso and to the macroscopic theory. The remainder o the book is devoted to electromagnetism, and contain a great deal of both mathematical and physica interest, including wave theory. A particularl interesting section is devoted to electromagneti shock-waves.

But, it may be asked, is all of this properl described as special relativity ? It comes very nea to being a general theory in which physical phenomen are mapped upon a flat Minkowskian four-spac instead of upon a curved space as in general relativit proper. It is admittedly a theory in which Lorent invariance is the dominating feature, and this doe perhaps legitimize its description as special. It ma be hoped that the second volume on general relativity promised by the publisher on the dust-cover, will i fact appear, for the present volume stimulates an appetite for more. The foundations of a furthe olume are here laid by a consistent use of tensor nd geometrical methods.

The book is full of wise saws and modern instances, ll eminently quotable if space did but permit. It is heerful in style, profusely illustrated by diagrams, nd beautifully printed. That its author himself directs attention to the debatable nature of some of is work in no way lessens its interest, but on the ontrary makes it all the more stimulating. The ure mathematics in it is alone sufficient to make it n important contribution to the literature of elativity.

H. S. Ruse

THE ORIGINS OF INTELLECT

he Child's Construction of Reality

y Prof. Jean Piaget. (Translated from the French
y Margaret Cook.) Pp. xiii+389. (London : Rout-
edge and Kegan Paul, Ltd., 1955.) 25*s.* net.

THIS is a companion volume to Prof. J. Piaget's earlier book on "The Origins of Intelligence in he Child" and should be studied in close connexion with it. In his earlier work, Prof. Piaget aimed to define the processes by which the young child comes o create an external world ; in the present volume, e devotes his attention more specifically to the nature of the world created. In short, we are now oncerned with the products of the child's thinking ather than with the thought processes themselves. None the less, the two aspects—subjective and bjective—are so closely related that an independent reatment of either is scarcely possible. For this eason, it is necessary to consider the two books ssentially as one.

The growth of the child's conception of external eality is treated by Prof. Piaget under four main spects : first, the development of object-concepts nd the correlated treatment of objects as being oth individual and permanent ; secondly, the volution of a spatial framework common to all ensory modalities ; thirdly, the development of deas of causal relationship ; and fourthly, the rganization of a temporal field endowing external vents with some measure of coherence. These four rocesses, which are of course closely inter-related, re supposed by Piaget to develop through a series f well-marked stages, and his main task in the resent book is to reconstruct the nature of the hild's world at each stage. In some measure he ould appear to succeed. The main theoretical onclusions derived from the two studies are brought ogether in a final section of this volume.

Although Prof. Piaget's systematic psychology s difficult, and at times obscure, his work brings ut a number of points of the highest interest and mportance. For example, his careful observations f the earliest reflex patterns make it clear that some measure of adaptation of response to the finer haracteristics of the stimulus field appears to be resent *ab initio*. This makes possible a theoretical reatment of reflex action much less rigid and mechan- tic than is *de rigueur* in present-day psychology, and ermits an altogether easier transition from the more o the less automatic varieties of behaviour. Again, Prof. Piaget's treatment of spatial perception clearly rings out that this activity, from a genetic point of iew at least, cannot be considered apart from the study of movement. Space, as he rightly points out, s an organization of movements such as to impose upon perception spatial relations that are increasingly precise and coherent. More generally, space may be regarded as a product of interaction between the organism and the environment in which it is impossible to dissociate the content perceived from the motor activity of the percipient. Although statements of this kind are perhaps too broad to convince, they serve at least to focus attention upon the rôle of action in the growth of our knowledge of the external world. Prof. Piaget's evidence may also be of great value to neurologists and others interested in the breakdown of spatial perception in abnormal states of the central nervous system.

Although Prof. Piaget bases his arguments throughout on empirical considerations, it cannot be said that the material presented in this volume possesses any great evidential value. It consists in the main of some two hundred observations—some little better than anecdotes—which the author has made on three young children (presumably his own), and no attempt is made to confirm the findings by means of appropriate large-scale inquiry. Indeed, many of these observations, despite their undoubted perspicacity, do little more than provide apposite illustrations of the author's theoretical contentions. Examples have great value so long as they are not confounded with evidence. Can we be quite sure that Prof. Piaget is himself free from this source of confusion ?

This book is original and thought-provoking. Prof. Piaget is perhaps the last of the great psychological system-builders. Although a whole host of empirical researches have been woven into the fabric of his system, it remains at bottom personal, speculative and unverifiable. It is not science, but it may well be the necessary precursor of a scientific psychology.

O. L. Zangwill

ARRESTED GROWTH IN ARTHROPODS

The Physiology of Diapause in Arthropods

By Dr. A. D. Lees. (Cambridge Monographs in Experimental Biology—No. 4.) Pp. x+151. (Cambridge : At the University Press, 1955.) 12*s.* 6*d.* net.

THE periodic arrest of growth or reproduction that is so characteristic of the life of arthropods in temperate latitudes forms one of those subjects which provide problems of the greatest theoretical interest and at the same time are of much practical importance to the applied biologist and the farmer. As his title implies, in this latest volume in the Cambridge Monographs in Experimental Biology Dr. A. D. Lees is concerned primarily with the more fundamental aspects of diapause : the physiological nature of the arrest and the ways in which its timing is regulated to fit in with the possibilities of life at each season. At one time diapause was regarded primarily as a state of subdued metabolism. Then it came to be thought of rather as an arrest of growth, the reduced metabolism being secondary ; and when growth in the insect was shown to be dependent upon the secretion of hormones, the theory was put forward by Wigglesworth that the immediate cause of diapause was a failure in this secretion. By and large that conception has been supported by experiment : in the pupa in diapause the neurosecretory cells in the brain are inactive.

But many insects, during the summer months, can pass through a number of generations without any arrest. With the approach of autumn diapause supervenes. By what token does the insect know that winter is coming? During the past few years it has been shown, in a wide range of species, that the absolute day-length is the most important sign: as soon as the light period is reduced to twelve or thirteen hours diapause supervenes. Falling temperature and reduction in the nutritional value of the foliage are important in varying degrees in different species; in some these factors may override the effect of day-length. It is also interesting to note that in at least one insect, the larva of a dragonfly, the *change* in day-length after the summer solstice is the important factor. What is still obscure is the nature of the connecting links between the duration of illumination and the inactivation of the neurosecretory cells in the brain. Presumably some photochemical reaction is the first step. The papers dealing with this rapidly developing subject are many of them scattered among the Russian and Japanese journals. One of the most valuable features of Dr. Lees's book is that all this material is critically assessed for the first time.

Since the classic researches of Duclaux it has been known that a more-or-less extended period at a very low temperature is necessary in order to 'break' diapause and to bring the insect to a state when it can once more develop in a favourable environment. This apparently mysterious change has been put in a proper perspective by the work of Andrewartha, who has pointed out that this progressive change is affected by temperature just like any other physiological process; but that it has an unusually low temperature optimum, usually around 5° or 10° C. The nature of this process, sometimes called 'diapause development', is still obscure.

All these matters, as described by Lees, make a fascinating story, closely argued and well written.

MINERAL DRESSING

An Introduction to Mineral Dressing

By E. J. Pryor. Pp. xii+649. (London: Mining Publications, Ltd., 1955.) 70*s.*

THIS, the first text-book on mineral dressing to be published in Great Britain since 1923, is based upon the elementary course in mineral dressing given to students of the Royal School of Mines, London. It is good in its conception and in much of its execution, especially the general lay-out and arrangement of subject-matter. Criticisms in this review are intended to be read in the light of the essential quality of the book; they are also intended to direct attention to shortcomings which, it is hoped, will be rectified in a second edition that the book well deserves.

It contains a very great deal of information, much more than might be expected in an introduction to the subject; indeed, in some sections, the author goes into great detail, much of it unnecessary and possibly disconcerting to those taking an elementary introductory course. Such people are, or should be, concerned with principles—as the author implies on p. 2. It seems out of place in an introduction of this sort to discuss, as the author does in places, details of what the alert [*sic*] shiftsman should do in controlling a mineral dressing plant; such details properly belong to practical application of principles

The style in places is somewhat pedantic; this may sometimes lead to a confusion in the mind of the reader, who may find it necessary to read some parts two or three times to be certain of what the author means. It may, perhaps, be unfair to selec part of one paragraph to illustrate this, but the following three consecutive sentences which appear in the first chapter could well have been more simply expressed: "A problem in physics can be analysed as Einstein shows, into three phases—the event, its signal and the effect produced on the observer Basic technology, as used in mineral-dressing research seeks to influence the nature of the signal, either by initiating the event or steering its course, and then by substituting for the observer a piece of apparatus which reacts specifically to the signal. With controlled initiation of noumenon, distinctive quality in phenomenon, and unilateral separatory reaction applied technology steps in". These, and othe similar descriptions, could deter a timid reader.

In the quotation made above the term 'mineral-dressing' has a hyphen; elsewhere in the book it ha not. This is typical of lack of attention to detail in writing. There is no uniformity in abbreviations *foot* may appear as foot, ft. or ′; *specific gravity* may be written in full or as sp. gr., s.g., or S.G. Th word *pennyweights* is given three different abbreviations; the British Standard series of sieves is referred to in different places as the B.E.S.A., the B.S.I., o the B.S. series; other terms have two differen abbreviations. The terms gravity, specific gravity and density (no units expressed) are used interchangeably; an example of this occurs in Table 12 where one part of the table is headed: "Bath S.G.= 2·70"; the other part is headed: "Bath Density= 2·80". The value of surface tension for water i given as 72·3 dynes instead of dynes per cm.; n temperature is stated. There are many mor examples of this lack of attention to detail.

It is surprising to find in this book, where Brownia motion is called pedesis, that space is devoted t explaining the significance of the suffixes *-ous* an *-ic*, as in ferrous and ferric, and that sodium hydroxide is called sodium hydrate. But perhaps the most remarkable feature of the book is the almost complete absence of mathematical approaches and explanations. One or two formulæ are given; but the author could have made some of his explanation much simpler if he had used mathematical aid Less than a quarter of the 233 figures have caption Some of the figures are poor and include numbere or lettered parts which are not referred to in th text.

The inclusion of a glossary of terms is good, but th glossary is spoilt by incompleteness and by th seemingly haphazard way in which items have bee selected for inclusion; for example, the word 'flotation' is included, but not 'flocculation'. Similarly the index is incomplete; for example, the Chance process is included, but not the Rheolaveur.

Inadequate attention to details of presentatio detract from a book which could well have bee outstanding. The general method of presentation commendable. It is to be hoped that there will be second edition in which uniformity is ensured, which certain sections (especially those on the physic and chemistry of pulps and on coal cleaning) a improved and from which details of plant operatio are omitted.

S. G. WARD

An Introduction to the Electronic Theory of Valency

By Dr. J. C. Speakman. Third edition. Pp. vii+180. (London: Edward Arnold (Publishers), Ltd., 1955.) 10*s*. 6*d*. net.

OUR ever-increasing knowledge of the structure of molecules and of the bonding of the component atoms not only expands the meaning of the term 'valency' but also makes a text-book account of it difficult to write. The second edition of Dr. J. C. Speakman's well-known introduction to the subject was published in 1943, and it is not surprising that he has now drastically revised it. In the new edition, he has changed the word 'modern' of the title to 'electronic' and has divided his work into two parts. The four chapters forming Part 1 deal, at sixth-form level, with the three chief types of bonds, and the treatment is but little changed from that in the second edition.

Part 2, however, he has almost completely rewritten. In a new chapter (5), without the use of any mathematics, Dr. Speakman has essayed to expound, in what he calls "a pictorial and descriptive way", the molecular configuration of electrons both from the valency-bond and from the molecular-orbital approach. The titles of Chapters 6–11 remain unchanged, but the subject-matter has been rewritten from the modern point of view. The hydrogen bond now gets six pages. Chapter 12 contains an interesting discussion of the meaning of the term valency and of the present-day position of the concept.

Throughout Part 2 Dr. Speakman, while admitting difficulties, apparent contradictions and conflicting views, is temperately critical and nowhere dogmatic. Implicit in his attitude to the subject is the advice to accept approaches to truth for their usefulness and not to let ideas on valency crystallize. His book is a praiseworthy attempt to give a simplified account of the present-day position of this concept.

G. FOWLES

Annuaire pour l'An 1956

Publié par le Bureau des Longitudes, avec un Supplément pour l'An 1957. Pp. viii+729. (Paris: Gauthier-Villars, 1956.) n.p.

THE "Annuaire" for 1956 of the Bureau des Longitudes, together with a supplement for the year 1957, consists of tables, definitions and articles contained on 614 principal and 121 supplementary pages, and several additional folding diagrams illustrative of the text.

The Bureau des Longitudes, constituted on June 25, 1795, by the then French National Convention, consists of fourteen members and six additional members, all of them French nationals, together with thirty internationally distinguished correspondents, not necessarily of French nationality (three are British). It is charged with making recommendations for the improvement of the different branches of astronomy and their application to geography, navigation and the physics of the Earth, and it is responsible for five other regular publications in addition to the "Annuaire".

The present "Annuaire" covers the following subjects: calendars—the principal world calendars and astronomical data associated with them, and tides; geophysics—the data of meteorological, atmospheric electricity and terrestrial magnetic phenomena; time—astronomical data concerning the Sun, Moon, major planets, comets and certain stars; tables of weights and measures; and physical and chemical constants. The articles are "Radio-électricité et opérations mondiales des longitudes", by B. Decaux, and "Les récepteurs photoélectriques", by A. Lallemand.

A Short History of Medicine

By Prof. Erwin H. Ackerknecht. Pp. xviii+258. (New York: The Ronald Press Company, 1955.) 4.50 dollars.

DR. ACKERKNECHT, an accomplished scholar, is professor of the history of medicine in the University of Wisconsin. He has here set himself to provide medical practitioners with a short and simple account of the development of their art and has succeeded admirably The work is concise and well balanced; but perhaps its most outstanding feature is the exceptional skill shown in treating the very intricate developments of the first half of the twentieth century—precisely the period where most such short histories tend to fail. This last chapter is so well done that many practitioners will find the volume a useful reference desk-book which they may conveniently consult for the dates, circumstances and authors of the main modern treatments and remedies. The historical perspective is well maintained throughout though, in my opinion, later editions would gain by condensing or telescoping the pre-Greek medical systems. These are of great interest and are well treated; but their bearing on scientific medicine is too remote to appeal to the audience for which this book is so particularly well designed. Further space might be saved on illustrations, the selection and reproduction of which show less of the care lavished on the text. These are minor and easily reparable faults in a work which I would heartily recommend.

CHARLES SINGER

Stratigraphic Geology

By Maurice Gignoux. English translation from the Fourth French Edition, 1950, by Gwendolyn G. Woodford. (Series of Geology Texts.) Pp. xvi+682. (San Francisco: W. H. Freeman and Company; London: Bailey Bros. and Swinfen, Ltd., 1955.) 9.50 dollars; 80*s*.

THE "Géologie stratigraphique" of Maurice Gignoux has been justly famous as an excellent exposition of stratigraphy as seen from the French point of view. Now that its fourth edition has been translated, it has become available to those who prefer to read it in English. The book has not changed its character as a result of G. G. Woodford's successful effort (translations of this kind are notoriously difficult); it has remained intensely French. There is the elegant and didactically effective method of dealing with typical areas in detail, leaving the rest of the world to a generalized treatment. Most examples have been taken from France, and the Alps have received special attention. Herein lies the chief value of the book for the English-speaking reader.

Similarly, references are particularly numerous for France and French territories, especially North Africa. In this edition, the questions of the Sahelian and of the Nummulitic formations of Egypt, Tunisia and Algeria have received careful attention. On the other hand, non-French Continental and British publications have been considered in a very uneven manner, but this is excusable in a work of world-wide scope.

F. E. ZEUNER

NEW METHODS OF PREPARING BLOCK COPOLYMERS

By P. E. M. ALLEN, J. M. DOWNER, G. W. HASTINGS, Prof. H. W. MELVILLE, F.R.S.,
P. MOLYNEUX and J. R. URWIN
Department of Chemistry, University of Birmingham

In recent years increasing attention has been given to the problem of the synthesis of block copolymers; that is, of copolymers in which the long-chain molecule contains long sequences of each type of monomer unit, as opposed to the normal copolymer molecule in which the units are distributed quite randomly. The term 'block' copolymer is not standard. We use it to describe linear molecules, whereas branched structures, arising from the attachment of side-chains of one type of monomer unit on to a backbone of the other type, we call 'graft' copolymers.

During the past few years a number of methods for the preparation of block copolymers have been described[1-9]. In most of these methods the yield of block copolymers is small—sometimes of the order of 10 mgm.—and in many cases separation is complicated by the presence of large quantities of other material of high molecular weight. Another complication in some of these systems arises from the difficulty in distinguishing between block and graft copolymer structures. Of all the processes listed above, only that of Woodward and Smets[5] can safely be said to give high yields of an unequivocable block copolymer which may be separated and obtained in a form uncontaminated by homopolymer or graft and random copolymers.

A number of these methods are purely chemical, involving either the use of a bifunctional initiator such as the phthalyl peroxide used by Woodward and Smets, or the introduction of a labile terminal group on to the growing chain by means of a suitable transfer agent such as bromotrichloromethane[2]. Both these methods lead to a homopolymer of the first monomer A containing a labile end-group which may be used to initiate polymerization in a second monomer B, or to couple with a suitable terminal group in a polymer of B. The great advantage of this method is that the first block may be fractionated before proceeding with the second stage, which greatly simplifies the fractionation of the final product. The method described below in which a dihydroperoxide is used to polymerize styrene is of this type. A polystyrene having a terminal hydroperoxide group is obtained, which is fractionated, and fractions having suitable molecular weight are used to polymerize methyl methacrylate.

Alternatively, the block copolymer may be built up in one stage from a continuously growing radical, the change in character of the chain being effected by transferring the radical end from an environment of monomer A to that of monomer B. Methods such as that of Hicks and Melville[3], who devised a method by which polymerizing methyl methacrylate or acrylonitrile may be injected into a large excess of styrene, and that of Dunn and Melville[1] in which the growing radical passes through a phase boundary, from, say, styrene in oil phase to acrylic acid in water, may be included in this group. A method is described here which utilizes the trapped radicals remaining in the polymer particles when an emulsion polymerization is taken to completion.

The methods described so far must all lead to bloc copolymers of the type $A_n.B_m$, or the sandwich-typ molecule $A_lB_mA_n$, depending on the relative pro portions of the combination and disproportionatio radical termination reactions. The third metho does not have this limitation. The essence of th method is to rupture the polymer chain by som mechanical method such as mastication[8], ultrasoni irradiation[4,6], or γ-radiation[9]. Such degradation i not accompanied by the depolymerization reactio characteristic of thermal degradation. If two differen polymers are degraded together, as described belov a cross-termination of the radicals results in a bloc copolymer. Alternatively, a polymer A may b degraded in the presence of monomer B as describe by Henglein[4].

The Dihydroperoxide Method

Monomeric styrene was polymerized in bulk usin *m* di-(hydroperoxy-*iso*propyl) benzene at 50° C. Th polymer formed was freed from initiator by suc cessive precipitations from benzene to methano The presence of hydroperoxy groups in the polyme has been demonstrated by the method of Wagne Smith and Peters[10]. The polymer was then fraction ated by a benzene–methanol solvent–precipitan system.

The second stage was carried out in emulsio The hydroperoxy-ended styrene was dissolved i methyl methacrylate and the solution emulsified wit a 'Manoxol O.T.' soap solution. The polymerizatio was initiated by ferrous ions according to the redo mechanism:

$$R.OOH + Fe^{2+} \rightarrow RO— + OH^- + Fe^{3+}$$

The polymerization was carried out under oxygen free nitrogen at 0° C. In a typical run the tota weight of polymer would increase by about 50 pe cent.

A turbidimetric titration of a benzene solution c the polymer against methanol revealed the presenc of considerable quantities of polymer intermediat in properties between polystyrene and polymeth methacrylate. The turbidimetric titration techniqu is described in more detail below.

A full-scale fractionation was carried out using th benzene–methanol system. Nine fractions were take and their polystyrene content determined b examination of the absorption maximum at 2620 A One fraction of 0·58 gm. was found to be pure poly styrene; three fractions, of total weight 2·28 gm had a styrene content of 82–89 per cent; tw fractions, amounting to 0·22 gm., contained 6 and 69 per cent styrene; and the remainde contained 1·39 gm. of polymer containing 8 pe cent styrene. It is suggested that the 82–89 pe cent styrene fractions arise from polystyrene containing one hydroperoxide group, whereas th 68 per cent fraction comes from dihydroperoxy polystyrenes.

The Emulsion Method

It has been established[11-13] that the site of the reaction in an emulsion polymerization lies in the polymer particles formed in the initial stages. The reaction is maintained by diffusion of monomer and initiator radicals into the particles from the aqueous medium. A large polymer radical cannot diffuse out of its particle into the aqueous phase, so the only way in which it may be terminated is by the diffusion of another initiator radical into the particle. If the generation of initiator radicals is stopped, the polymer radicals unterminated at that stage will remain trapped in the particles even when the polymerization ceases on the exhaustion of monomer. If an emulsion of a suitable second monomer is now added, the new monomer will diffuse to the polymer particles and, in those particles which contain trapped radicals, polymerization will be resumed, yielding block copolymer molecules.

We have used this process to prepare block copolymers of vinyl acetate and methyl methacrylate. Vinyl acetate emulsions stabilized by 'Manoxol O.T.' were irradiated at 20° C. by γ-radiation from a 100-curie cobalt-60 source. The polymerization was followed dilatometrically, and when the process had reached ~70 per cent conversion the source was removed. The polymer latex was mixed with a methyl methacrylate emulsion (a manipulative delay of 30 min. usually occurs) and the second stage of the polymerization was followed dilatometrically at 40° C.

The rate of polymerization of vinyl acetate by γ-radiation has been found to be extremely rapid and G values of 10^6 for monomer conversion have been found. In a typical run using a 20 per cent by volume vinyl acetate emulsion and a dose-rate of $6 \cdot 5 \times 10^{18}$ eV./c.c./min., a rate of conversion of 0·11 gm. monomer per min. was observed in a volume of 2·5 ml. This is equivalent to a G value of 94,500 monomer molecules/100 eV.

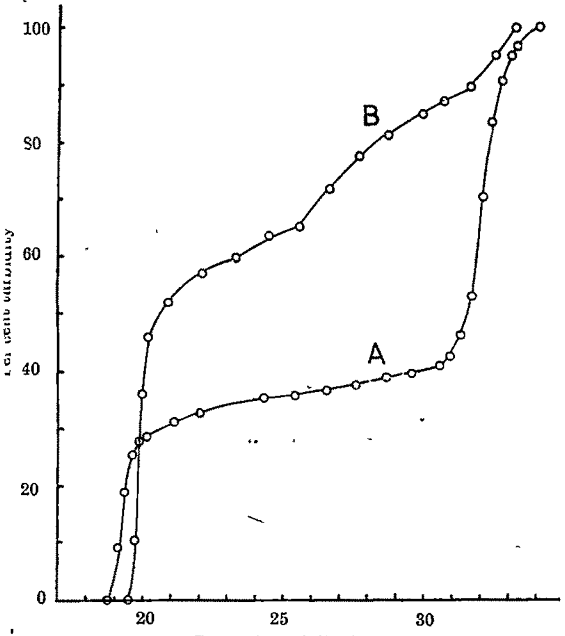

Fig. 1. (A) Turbidimetric titration of a solution of polyvinyl acetate and polymethyl methacrylate. (B) Turbidimetric titration of a solution containing vinyl acetate–methyl methacrylate block copolymer prepared by the emulsion method

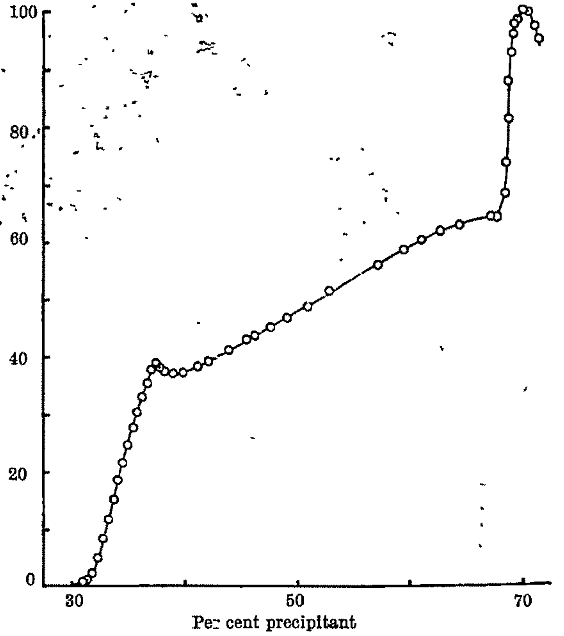

Fig. 2. Turbidimetric titration of a solution of polystyrene and methacrylate after ultrasonic irradiation

The latex formed under such conditions converted a methyl methacrylate emulsion at a rate of about 1 per cent per min.

Turbidimetric titrations were carried out on the polymer produced. This technique has been described elsewhere[14]. It is essentially a titration of a very dilute solution of the polymer (about 5 mgm./100 ml.) against a precipitant, the amount of polymer precipitated at a given point being indicated by the rate of increase in the turbidity of the solution. Curve A in Fig. 1 represents a turbidimetric titration of an acetone solution of polyvinyl acetate and polymethyl methacrylate against water. Percentage turbidity, that is, the ratio of optical density to optical density at complete precipitation, is plotted against the percentage of added water. It will be seen that the turbidity increases rapidly between 19 and 22 per cent water and again between 31 and 35 per cent. These steps may be attributed to the precipitation of the polymethyl methacrylate and polyvinyl acetate fractions, respectively.

Curve B is a titration of a polymer prepared by the methods described above. A sharp step is again observed between 19·5 and 22 per cent water, so presumably some polymethyl methacrylate is formed, either from hydroxyl radicals trapped in the vinyl acetate latex or from polymerization initiated by heat or a trace of peroxide in the methacrylate emulsion. However, precipitation continues at a steady rate beyond the 22 per cent water point until, in the region of 33 per cent water, the precipitation of large quantities of polyvinyl acetate causes the suspension to coagulate. The titration curve is indicative of a polymer mixture containing large quantities of polyvinyl acetate, a certain amount of polymethyl methacrylate, and a considerable amount of block copolymer varying widely in composition and molecular weight.

Ultrasonic Method

When a polymer solution is irradiated with ultrasonic waves, degradation occurs under cavitating conditions. It is now established that this occurs with the production of free radicals[15], which are removed presumably by reaction with solvent molecules.

Degradation of polymer in the presence of a second monomer would be expected to result in the formation of a block copolymer, the radicals produced by chain scission initiating polymerization of the monomer. This has been tried successfully for the system polyacrylamide–acrylonitrile[4].

In the method described here, two different polymers are degraded simultaneously in solution, the polymers being chosen so that their radicals combine when they interact. A suitable pair of polymers is polystyrene and polymethyl methacrylate.

Fig. 2 shows the titration of a mixture that had been degraded for 12 hr. This shows a pronounced discontinuity at 37 per cent methanol, and the turbidity increases continuously between this and 68 per cent, at which point polymethyl methacrylate is precipitated. Polystyrene itself is normally precipitated between 31 and 38 per cent methanol. A degraded polystyrene sample is almost completely precipitated at 37 per cent methanol (turbidity, 90 per cent), and polymethyl methacrylate does not begin to precipitate until about 68 per cent methanol. With an undegraded mixture of the two polymers, the curve shows a horizontal portion between the precipitation limits of the two polymers. The centra portion of the curve thus represents a third molecula species present in the mixture—in this case a bloc copolymer formed by cross-termination of the radicals Its structure would probably be of the 'sandwich type, since when any copolymer is formed it ca undergo further degradation. The copolymer appear to have a wide distribution of molecular weight, bu this is expected since ultrasonic degradation is random process, and radicals produced will have wide range of sizes. Secondary copolymer degradatio will also complicate the picture.

IODINE AND FLUORINE IN NUTRITION

THE final meeting of a series on "Nutritional Requirements and Food Fortification", arranged by the Nutrition Panel of the Food Group of the Society of Chemical Industry, was held on April 11 ; the subject was "Iodine and Fluorine". In the first part of the meeting, dealing with iodine, the speakers were Prof. M. M. Murray (Bedford College, University of London) and Mr. J. C. M. Holman (Chilean Iodine Education Bureau) ; in the second part, on fluorine, the speakers were Prof. Murray, Miss J. R. Forrest (dental officer, Ministry of Health), Dr. G. Wynne Griffith (medical officer of health, Anglesey) and Dr. J. Longwell (Department of the Government Chemist). Copies of the various papers had been circulated in advance and the authors spoke briefly, illustrating the chief points with explanatory slides. The following account includes points raised in the discussion and the replies.

In the first part of the meeting, on iodine, Prof. Murray dealt with the uptake of iodine, the synthesis of thyroid hormones and their state in the circulation. It was pointed out that when the supply of iodine is inadequate, the thyroid in the first place becomes hyperplastic and increases in size, because the low level of circulatory thyroid hormone stimulates the release of thyroid-stimulating hormone from the anterior lobe of the pituitary.

Enlargement of the thyroid gland in adolescents and goitre in adults occurs to a greater or lesser degree in most parts of the world, even at the present time. Where the dietary intake of iodine is abundant, namely, in Iceland and Japan, the thyroid gland is small, rich in iodine and of comparable size in males and females.

It has long been considered that the iodine content of the water supply is a determining factor in the occurrence of endemic goitre. In the United States, surveys showed that areas with waters having 3 µgm./litre iodine were free of endemic goitre ; i many places in England and Wales this level i inadequate. Other factors in soil and water play a important part ; one of these may be the wate hardness, since a significantly greater incidence o thyroid enlargement in children occurs in place where the water is hard as compared with place where the water is soft, but with comparable iodin content. For rats on low iodine diets, a high intak of calcium carbonate has been shown to be goitrogenic.

The daily intake of iodine for man has been pu at 100–150 µgm. ; only about 10 per cent of this i usually supplied by the water, even in areas fre from goitre, so the remainder must be obtained fro food sources. Since only fish, fish products and se foods are rich in iodine, many people must exist o the verge of inadequacy. It is for this reason th the iodization of salt has been introduced into man countries, some by compulsion ; it would appe wise to advocate the use of iodized salt in a countries, including Great Britain.

Mr. Holman emphasized that endemic goitre still widespread ; and because this produces advers effects on the general health, social well-being an educability of the population, there is an ove whelming necessity for preventive measures, that i to raise the intake of dietary iodine. The mo practical method of doing this, and thereby erad icating endemic goitre, is by the use of iodized sal a procedure actively encouraged by the Wor Health Organization. The community use of iodize salt as a prophylactic has been practised for mo than thirty years, with remarkable decreases goitre incidence in the United States, Switzerlan New Zealand, Poland and elsewhere. The level iodization is 1 part of potassium iodide in 10,00 200,000 parts of salt. These levels respective upply 500–100 μgm. of iodine per day per person, nd even at the higher level no deleterious effects ave been found. In Great Britain the level recom-nended by the Medical Research Council is 1 part in 0,000 of salt.

The iodization of salt is easy and inexpensive nd the methods of production were clearly explained. he iodization of 'free-running' vacuum-dried salt, which is extensively used in more developed coun-ries, is also simple. For the crude, coarse salt, roduced in under-developed areas, a conveniently imple technique has been devised whereby a con-rolled mixing of the required weight of potassium odide or iodate, already mixed with inert powder uch as calcium carbonate to give greater bulk, is ed into a bulk mixer.

Potassium iodate has been shown by experimental ests on man to be effectively used by the thyroid land and has been used for the iodization of salt ith good results in certain countries for the past ew years. The stability of salt iodized by potassium odide was considered and data presented to show hat loss of iodine is not appreciable from dry and ree-running salt, if it is free from impurities and ontains a stabilizer, is packed in impervious linings nd stored in a dark, cool place for several months. 'or open pan and solar salts stored in hessian bags, articularly in adverse climatic conditions, potassium odide is not suitable; the loss is considerable, and herefore potassium iodate should be, and has been, fectively used because of its greater stability. It as not considered necessary to change the methods f iodization now in use in Great Britain.

To those who still have the impression that iodized alt might be unsuitable for certain individuals, the eply is that the amount of iodine in certain sea ods is considerable; and that the use of the high-vel iodized salt has not provided any evidence for is belief. Changes in the distribution of endemic oitre take place at all times, the incidence has ecreased markedly in some places and increased in thers; this is considered to be due to changes water supplies, dietary habits and population istribution.

Prof. Murray opened the second part of the eeting, on fluorine, emphasizing the following oints. Fluorine occurs in bones and teeth, hich consist mainly of calcium hydroxyapatite $Ca_3(PO_4).Ca(OH)_2$), the fluorine replacing OH oups in the lattice. The proportion of fluorine esent increases with age and in proportion to the mount present in the water supply or the diet and hen there is exposure to industrial sources of uorine. So far, it has not been possible to prove at fluorine is an essential dietary element; although is now generally accepted that the use of water pplies with 1 or more parts per million (p.p.m.) of uoride is associated with a lower incidence of dental ries than waters with less.

Fluorine can accumulate in bones, and excessive takes produce osteosclerosis, increased density and ostoses. However, the average daily intake in ritain is about 1 mgm. (water level of 0·2 p.p.m. orine) and 2·5 mgm. if the water has 1 p.p.m. orine, and this latter quantity is insufficient to use excessive accumulation. Severe outbreaks of orine poisoning in animals have occurred in ritain, due to the eating of pastures contaminated ith fluorine dusts from industrial undertakings, and remains to be proved whether this 'neighbourhood zard' affects the human population.

A high intake of sodium fluoride in laboratory animals can cause decreased kidney tubular function and inhibition of gastric acid secretion; the amounts used in these tests are outside the range likely to be encountered in endemic fluorosis.

Miss Forrest dealt with the matter of greatest interest, namely, caries incidence and fluoride in the water supply. In the United States a definite inverse relationship has been proved between caries in children and the level of fluoride naturally present in water. The best effects are seen in those born and living up to eight years in a fluoride area, although some protection is seen in children who are new-comers. In 1944 in South Shields (water 1·4 p.p.m. fluorine) the 5–14-year old children had 45 per cent less caries than in North Shields (water free from fluorine). The mechanism by which the fluorine gives this protection is not known; one suggestion is that it is due to the increased proportion of fluorapatite in the enamel. The various degrees of 'mottling', with and without staining, were illustrated by excel-lent coloured slides. Mottling occurs in 90 per cent of the population where the water has 5–6 p.p.m. fluorine, but at 1 p.p.m. mottling is less frequent and very mild. More recent surveys in areas in the United Kingdom with 5·8, 3·5, 2·0 and 0·9 p.p.m. fluorine, respectively, and fluoride-free areas have confirmed the findings in the United States. In the area with 0·9 p.p.m. there was 60 per cent less caries than in a trace-fluoride area; in the former 30 per cent of the children were free from caries and only 30 per cent had noticeable mottling.

Artificial fluoridation to a level of 1 p.p.m. was started in certain communities in the United States and Canada in 1945; the incidence of caries in children before and after has been compared with control non-fluorine areas. The results show that caries incidence has steadily decreased, and after the ten years by about 60 per cent, in the fluoridation areas, but remained unchanged in the control areas. Fluoridation at 1 p.p.m. is about to be introduced into four areas in the United Kingdom.

Dr. Wynne Griffith described the signs and symp-toms of chronic industrial and endemic fluorosis in man, pointing out that radiological changes in the bones are not always associated with disability. Bone lesions and severe disability in a certain pro-portion of persons have been recorded from areas in India, China and South Africa with waters having more than 4 p.p.m. fluorine; in these places it is likely that malnutrition increases the deleterious effects of fluoride. Dr. Griffith quoted evidence that the normal human kidney can excrete fluoride well in excess of the proposed level of fluoridation; nevertheless, a recent report from an endemic fluorosis area (Hyderabad, Deccan, water 11·8–5·2 p.p.m. fluorine) records impairment of kidney function in a proportion of individuals; but this was not proved to be due specifically to the fluoride.

On the basis of certain general health surveys in natural fluorine and fluoridation areas, Dr. Griffith concluded that available evidence gave no support to the contention that 1 p.p.m. represents any hazard to human health.

Mr. Longwell gave useful figures which he has recently obtained for daily fluoride intakes in Britain. These were: men 3·2 mgm., women 2·2 mgm. and children 1·2 mgm., amounts comparable to those recorded in the United States. He then dealt with the practical aspects of fluoridation of water, for which either sodium fluoride or sodium fluorsilicate is used. The proportioned addition to the main water supply of a solution of the chemical compound is carefully controlled by special meters. This addition should be made at the final stage of water treatment, when chlorination takes place. Frequent estimations of the fluoride content of the domestic supply mus be made and records kept.

Time limited the discussion on fluorine ; but i answer to a leading question, Miss Forrest made i quite clear that the fluoride-level in water is a important, but not the only, factor influencing toot structure and the incidence of caries.

AUTOMOBILE FREE-PISTON ENGINES

By F. D. ROBINSON
Engineering Laboratory, University of Cambridge

NEARLY twenty years have passed since Sir Frank Whittle's first gas turbine ran and six years since the Rover car JET I was driven around the circuit at Silverstone ; yet there is still no commercial vehicle driven by gas turbine anywhere in the world other than those few used for experimental purposes. Now, according to a report in *The Times* of April 16, General Motors have developed a free-piston engine for passenger motor-car service. Since the same Company has already produced an automotive gas turbine, it is perhaps a significant comment upon the prospects of gas turbines applied to vehicles that further research has been expended on an alternative prime mover.

It must be obvious to most engineers, in spite of Chryslers' success in the United States, that the gas turbine is at present still an unsuitable engine for the passenger car as visualized in Great Britain, where economy and compact size are of paramount importance. Perhaps one day when blade cooling has been developed, component efficiencies raised, regenerator sealing problems solved and turbine design improved to a level where part-load performance can match full-load performance, then the gas turbine may compete with the petrol and the diesel engine. It is, in fact, arguable if the effort put into producing a suitable small gas turbine would not bring a much greater reward if expended in designing small diesel engines.

Superficially, the new free-piston engine presents many attractive features. It should first perhaps be noted that this type of engine is not at all new. The Junkers version was used to compress air during the Second World War. In the United States a few large gas generator plants of around 1,000 and 1,500 s.h.p. have been built, mostly experimentally, by Baldwin–Lima–Hamilton and by Cooper–Bessemer, and in Britain free-piston air compressors delivering 100 cu. ft. of air per minute have been in use for some years. It is in France, however, where development has been nearly as intensive as that devoted in Britain to gas turbines, that the greatest progress has been made, and SIGMA with their 1,200 s.h.p. gas generator have achieved some notable results. A standard design is available and is in commercial use providing the motive power for mine-sweepers, trawlers, merchant ships, base power generation and pumping sets.

From a thermodynamic point of view, a gas generator is the combination of a diesel two-stroke engine, which fulfils the dual functions of a self-driven compressor and a combustion chamber, with a gas turbine using the high-pressure exhaust gases released from the diesel to produce the useful work. Since the work output of the diesel is expended in compression, it becomes logical to compress by a reciprocating piston attached to the diesel piston an so to omit the usual crankshaft and associate bearings. Various arrangements have been propose and used ; but the travel of the diesel and compressor pistons is always limited only by pneumati and not by mechanical restrictions. The cycle is th pure constant-pressure cycle ; but since the diese cylinder contains the high-temperature gases and i only intermittently exposed to them, a very muc higher peak temperature and compression ratio ar possible than when a simple gas turbine is used. O the other hand, the intermittent process in the diese cylinder makes it impossible for the engine to handl the huge quantities of air associated with a simpl turbine. As might be expected when due allowanc has been made for the losses which occur in practice the performance of a free-piston gas generator is compromise between that of the two engines c which it is compounded. Thus the power–weigh ratio is a little better than in conservative diese practice, but well below gas turbine possibilitie while the fuel consumption is always very muc better than gas turbine consumptions. In fact, a full load, economy is nearly equal to that of a diese and even at half load compares favourably with tha of a petrol engine.

Apart from these inherited merits, the free-pisto engine has advantages peculiar to itself and suited t its application to automotive use. Thus vibration very slight, so mountings can be of a simple natur It lends itself to considerable flexibility in installatio and thus it is quite feasible to place the turbine at considerable distance from the generator cylinde substituting a pneumatic drive for a mechanical on One or more generators may feed the same turbin or presumably vice versa. The torque characterist is very satisfactory, a large torque being produced zero turbine speed, while the response to acceleratic requirements both from an idling and from a cruisir speed are ideal. This cannot be said for the simp gas turbine as, if the compressor and compresso turbine are idling, the inertia of the combine rotating system is considerable and acceleration fro idling conditions is poor unless provided by gearin With the gas-generator the response is immediat the only fly-wheel effect being in the pow turbine.

On the debit side there are several features, pa ticularly of mechanical design, which suggest that will be a long time before this form of engine riva the standard types. Its advocates always emphasi the absence of crankshaft, bearings, poppet valv and cam-shafts in the free piston engine. These a not, in fact, components which give trouble, or, und good conditions of lubrication and filtration, wear all rapidly. In their place the free-piston engi imports several complications of its own. Accurate alignment of the four pistons and subsequent lack of distortion are required; non-return valves are freely strewn about the engine, so that leakage due to dirt, oil-varnish and distortion is always a possibility. Although there is no orthodox crankshaft, a light synchronizing mechanism is employed, while a fuel injector and its actuating mechanism are required. The two most sensitive features of the plant are the top ring of the exhaust piston and the gas turbine. It is possible by derating and by conservative design to sacrifice fuel consumption and achieve reliability with these components; but if run at full load, such evidence as is available suggests rapid wear of piston rings due to the compression pressures and temperatures, which are excessive compared with orthodox two-stroke diesels, where piston crown temperatures and ring sticking are always limiting features of design. Of course, it is well known that the working life of a passenger motor-car engine is passed almost entirely at part load, so that conditions are much less severe in this application. Similarly, the gas turbine can use low-temperature exhaust gases and so be made of non-strategic materials if the efficiency of the plant is compromised, or full load is maintained for short periods only. Matching of diesel and turbine over a wide range of speed and load is also known to be difficult.

Claims are made for the omnivorous nature of the free-piston engine. It is true that the free-piston engine will run on a wide variety of fuels—pea-nut oil is quoted—but so will the diesel engine, which has been well tested on palm oil, pea-nut oil, coconut oil, linseed oil and, what is more to the point, residual fuels. The vegetable oils are in point of fact prohibitively expensive, and in any event satisfactory combustion of a fuel is only a first essential; what is equally important is prolonged life of vital parts in face of attacks by products of combustion. This problem has not been solved for high-sulphur fuel oils in diesel engines and certainly not in free-piston engines.

It is praiseworthy that in the face of so many problems General Motors should pursue this line of research, and it is only concerns of such magnitude that can afford to investigate projects with a long chance of success. For, apart from the inherent difficulties of the free-piston gas generator, steady progress in the technical improvement of the diesel, leading to smaller, lighter and cheaper units, and even of the well-tried petrol engine, is still being made. General Motors are sensibly cautious upon the future prospects of the free-piston engine, but it will be interesting to watch the development of this slightly exotic prime mover, and to wonder whether it may be produced in a size one-fifth of the 250 h.p. engine General Motors quote as a respectable minimum.

INFRA-RED SPECTROSCOPY AND CHEMICAL INDUSTRY

By Dr. H. W. THOMPSON, F.R.S.

It is now generally accepted that much of the recent remarkable progress in the organic chemistry of complex molecules and natural products could not have been achieved without the help of the numerous modern physico-chemical techniques. Most of these new tools have a clearly defined sphere of utility. For example, chromatography is applied almost exclusively in the separation of mixtures or for purification of compounds, and isotopic tracers are for the most part used in the elucidation of reaction mechanisms. Infra-red absorption spectroscopy, on the other hand, can be applied in a wider sense. Its value in industry is twofold: first for qualitative or quantitative analysis, and secondly for the determination or clarification of molecular structure. In both these respects the range of applicability is enormous, and much of the information gained in the course of the work can be of great value in other connexions. The structural studies can be made with molecules in all states of aggregation, and the method is now pointing to a new line of attack on the nature of intermolecular forces and intermolecular complexes.

Many discussions on these applications of infra-red spectroscopy have been held during the past fifteen years, and they have served to illustrate the continual progress in many directions. Nevertheless, the symposium organized on April 9–10 by the London Section of the Society of Chemical Industry was opportune, for it provided an opportunity to take stock of the present position, not only as regards the experimental facilities now available but also in regard to the theoretical basis and possible extension of the different lines of application. The large attendance, and the diversity of problems which were raised, showed that the scope of this particular technique is still widening. It is now being used, in penetrating fashion, in the chemistry of fuels, textiles, paints, dairying, perfumes, polymers and resins, pharmaceuticals and antibiotics, and other general chemicals.

Industrial work requires two kinds of infra-red equipment, namely, (i) spectrometers with the appropriate accessories for use in research laboratories, and (ii) other apparatus for use on the plant in process control. The most urgent need in Britain at present is in the latter respect. Prism spectrometers of rugged stability are now commercially available for the region 1–40μ to meet all normal requirements. Although costs are still high, a choice can be made according to the spectral range to be studied, the resolving power required, and the speed and method of recording. Some general flexibility is also desirable so that accessories can be attached, such as long-path absorption cells, a reflecting microscope, or a low-temperature absorption cell. In view of the limited spectral range of the known photoconductive cells, it might be helpful if fast and more sensitive, spectrally black, bolometers could be developed. Also, although a satisfactory variety of synthetic crystalline materials for prisms and windows is now available, something might be gained from further examination of such substances as lead chloride. The resolving power provided by good commercial prism spectrometers is now adequate for most purposes, but the recent success in making cheap replica diffraction gratings has opened up the possibility of simple grating spectrometers. It is possible, in fact, that for more satisfactory work on band intensities, the higher resolving power may become necessary; but if such grating instruments are to be developed, more systematic work on filters should be undertaken.

The position as regards availability of instruments for flow-line control is less satisfactory, and this is where much help can be given to industrial production. For many years it has been clear that certain components of common industrial gas streams could be monitored continuously by means of their infra-red absorption. For such work, either dispersive or non-dispersive analysers can be used, measuring either the integrated infra-red absorption over a wide spectral range, or some selected band which has been isolated by means of filters or by a simple dispersing system. Typical components measured in this way include carbon monoxide and dioxide, sulphur dioxide, hydrogen sulphide, ammonia, acetylene, ethylene and other hydrocarbon gases. Much progress has been made in the United States and also in Germany with such instruments, in some cases leading to an effectively automatic process control. The older non-dispersive analysers use either a black-body detector with filters (negative type), or microphone detectors which are selectively sensitized to a particular spectral region (positive type). Improvements in both stability and sensitivity have been achieved by a combination of both types in the Perkin–Elmer 'tri-non' analyser. With all such equipment, the details of design must be carefully considered with specific reference to the gas stream involved, since in all cases the ease of determination of the main component is affected by the absorption of other substances present. Also, for plant operation, the most vital factor is obviously long-term reliability; but the difficulties in this respect have been overcome, and concentrations varying between parts per million and 90 per cent can be measured convincingly. An alternative method, using the so-called 'bichromator', is to use a simple prism spectrometer with split Littrow mirror, so that the absorption at two different wave-lengths can be compared continuously, one wave-length acting as a reference standard. For some purposes, this type of instrument has advantages over the non-dispersive analysers. The main conclusion is that there are scope and need for such plant control instruments in British industry. A few are already in use, and it is understood that others are to be installed for the analysis of water – heavy water mixtures.

Conventional infra-red analysis using prism spectrometers is being used on an ever-increasing scale. Among new examples are the determination of plasticizers, oil and rubber additives, copolymers, residual water in fibres, antibiotics, resins and paints. The pressed-disk technique has facilitated work with insoluble materials, although the quantitative background of this method needs further examination. Hitherto, most analyses have used the region 1–14μ, but the merits of other spectral regions are now becoming evident. Between 1μ and 3μ, where vibrational overtones are involved, more conveniently measurable thicker layers can be used, and several problems involving polymers, including the determination of end groups, have been solved.

Qualitative and semi-quantitative analysis has advanced significantly by use of 'differential spectroscopy'. If the absorption of the main component in a mixture is overlaid or masked by the absorption of other components, the background absorption of the latter may be cancelled out by use of a double-beam spectrometer in which a compensating cell is placed in the 'blank' beam. This method demands proper experimental care, but is capable of giving spectacular results. It has been applied successfully to many problems in the fuel industry and suggests a new approach to the discrimination between closely similar complex materials such as proteins, carbohydrates and polymer products. Meanwhile, the theoretical basis of infra-red quantitative analysis is now being examined critically. The optical densities at band peaks, which lead to the 'apparent' extinction coefficients, cannot really be regarded as satisfactory measures of band intensities, for they are much affected by the relatively wide spectrometer slits which are used in infra-red work, and by other instrumental factors. Unfortunately, therefore, quantitative data from different laboratories often disagree, and this has so far made it impossible to establish intensity values of universal applicability. The shapes and 'apparent' extinction coefficients of many vibrational bands have now been determined as a function of slit-width, and the experimental requirements for obtaining satisfactory 'reproducible' values of peak densities have been examined. At the same time, band intensities have been measured by taking the integrated absorption over the whole band. This latter method seems to provide a measure which is far less dependent upon spectrometer characteristics, and automatic integrating devices have therefore been developed. Whether it will prove better, as a regular procedure, for general analytical work, to use higher resolving power and the peak extinction coefficients, or to measure the integrated band areas, remains still undecided, but it should soon be possible to assess the relative merits of the two methods.

The use of key absorption bands for structural diagnosis has also reached an interesting stage. It is based upon the localization of certain molecular vibrations within a small group of linked atoms, and ceases to be of much value if nuclei of comparable mass are joined together by single valency bonds so that a larger part of the whole molecule is concerned in the vibration. A few more correlation rules may still be discovered, and there are suggestions that some characteristic differentiation of stereoisomers may be possible. However, the bulk of the useful data is now available, and more attention is being given to disentangling the influences within a molecule which cause the general rules to break down. The exact nature of the hydrogen bond is again under consideration, and interesting 'inter-space' group interactions have been found. It may, however, now be profitable to explore the use of intrinsic band intensities for diagnostic work. Results show that different types of a particular group can be distinguished in this way, and the comparison of the intensities of fundamental and overtone bands may sometimes be even more informative.

Among the ancillary techniques used for studying complex molecules, polarized infra-red radiation has been applied to ordered structures and crystalline materials, and the spectral changes arising from deuteration are sometimes instructive. The reflecting microscope has greatly simplified work on fibres such as silk or 'Terylene'. The α (helical folded) and β (open chain) forms of polypeptides have been distinguished, and natural and synthetic peptide materials have been compared. These methods have also been applied to the general problem of the crystallinity of polymers, which is so much related to their physical properties. In pharmaceutical chemistry, infra-red spectra are being used as a means of proving identity, for quantitative assay, and for unravelling the structure of steroids, hormones and antibiotics.

One new line of great significance is the study of inter-molecular interactions through the displacements of vibration bands. This may lead to valuable information about adsorption processes, adhesion, and the formation of intermolecular complexes in reacting systems.

Many of these more elaborate contributions to research problems are of real interest; but it is important not to lose sight of the more mundane and urgent needs of analytical process control mentioned above. There are hopeful signs that the necessary instruments may soon become available.

OBITUARIES

Prof. Megh Nad Saha, F.R.S.

The death on February 16 from sudden heart failure, at the age of sixty-two, of Prof. M. N. Saha has robbed India of one more of her leading men of science. He was well known for his distinguished researches, for his activity in scientific administration and for his other public activities. After an early education in India he came to England for post-graduate studies under Prof. Alfred Fowler at the Imperial College of Science and Technology, London. It was there that he developed his work on thermal ionization, which led up to 'Saha's equation', by which he will be remembered. By taking account of the important effect of pressure, as well as of temperature, in a gaseous mixture of neutral atoms, ions and electrons, he explained the increase in ionization as one moves outwards from the photosphere to the chromosphere of the Sun. His work led to important developments by R. H. Fowler and E. A. Milne in the study of the pressures and temperatures of stellar atmospheres. It has earned a permanent place in the history of astrophysics.

On going back to India, Saha returned to physics, and as professor of physics successively at the Universities of Allahabad and Calcutta he founded research schools on ionospheric problems and nuclear physics. He published many papers on a wide range of subjects, including the propagation of electromagnetic waves in the ionosphere, the escape of radio waves from the Sun, nuclear physics and spectroscopy. His position in the world of Indian science may be gathered from the many leading positions that he held from time to time. He was president of the Indian Science Congress, of the United Provinces Academy of Science (later the National Academy of Sciences), and of the Indian Association for the Cultivation of Science and the National Institute of Sciences. He was largely instrumental in founding the Institute of Nuclear Physics, Calcutta; as its director he was active both in training students and in supervising research work.

He was a member of the Board (or later Council) of Scientific and Industrial Research, which led to growing interest in the social relations of science, a subject on which he wrote a number of papers. As he grew older and became an established figure in his own country, he turned more and more to questions of education, industrialization, national planning and such details as river valley projects. His last paper of this kind appears on p. 923 of this ssue of *Nature*.] In 1951 he was elected to the Indian Parliament by a large majority as an independent member, having refused to stand as a party candidate. He loved fighting for causes which he felt to be right, even though by so doing he earned unpopularity in Government circles. But he retained a keen, active nterest in science, and only last year was one of the Indian members attending the General Assembly of the International Astronomical Union in Dublin. His sixtieth birthday was celebrated by a volume on his life, work and philosophy arranged by a committee of the Indian Association for the Cultivation of Science (see *Nature*, 174, 528; 1954). It is sad that he should have survived its publication for so short a time.

F. J. M. STRATTON

Mr. T. Harold Reade

THOMAS HAROLD READE, the third son of the late Thomas Reade, manufacturing chemist, of Wolverhampton, was born in 1889. He was educated at St. Paul's School, London, where he was a contemporary of Lord Montgomery, and at the University of Birmingham, where he graduated in science. During the First World War, Reade served in France and in Palestine, first with the 6th South Staffordshire Regiment and later with the Machine Gun Corps. On demobilization he went to Emmanuel College, Cambridge, where, under Dr. Hamilton McCombie, he carried out research on the preparation and properties of phenyltrimethylammonium perhaloids, perfecting methods for the determination of the constitution of these compounds. In 1921, Reade graduated and was appointed to the staff of the University of Aberdeen, where he became responsible for the teaching of organic chemistry, a duty which he performed with thoroughness and distinction until his retirement in 1945. A man of strong personality, a trifle impetuous, he was an inspiring teacher and a pleasant colleague.

Throughout his period on the University staff, Reade maintained an active research programme. Following on his work at Cambridge, he studied the addition compounds of halogens and quaternary ammonium salts, showing experimentally that the iodine in these perhalides is reducible but not oxidizable to molecular iodine and therefore is in a higher state of oxidation. Later, in collaboration with his research students, he investigated, among other problems, the simultaneous nitration of the nucleus and nitrosation of the nitrogen atom in a considerable number of dialkyl anilines by means of sodium nitrite in hydrochloric and sulphuric acids, finding a method of controlling the type of reaction that predominated. The numerous contributions which he made in these various spheres are recorded in the *Journal of the Chemical Society*.

In his retirement Reade devoted his leisure to golf and music; he was an accomplished performer on both the golf course, where on many occasions he represented the staff of the University of Aberdeen in inter-university competitions, and on the piano. His sudden death, on March 24, came as a great shock to his many friends; taken ill while playing his usual game of golf at his club, the Royal Aberdeen, he died a few hours later in hospital. He was unmarried.

R. B. STRATHDEE

NEWS and VIEWS

New Foreign Members of the Royal Society:

Prof. K. U. Linderstrøm-Lang

PROF. K. U. LINDERSTRØM-LANG, director of the Carlsberg Laboratory, Copenhagen, whose election as a foreign member of the Royal Society has recently been announced, is famous for his researches on proteins and for his pioneer work in the field of enzyme histochemistry. As a young man, his reputation was established by his acetone-titration method of estimating amino-acids; he followed this with a series of investigations on the physical chemistry of proteins, dealing *inter alia* with protein denaturation and various aspects of protein degradation by enzymes. His Lane Medical Lectures of 1952 on "Proteins and Enzymes" and his contribution to the Solvay discussion on proteins the following year show the breadth of his interests and his ability to apply theoretical treatment to his problems. One of the most interesting of his recent contributions has been the discovery and unravelling of the transformation of ovalbumin to plakalbumin. An investigator possessed of great manipulative skill, he has invented many ingenious methods of microanalysis which have enabled him to throw light for the first time on chemical reactions going on in individual cells. As an illustration, one may cite his elegant demonstration of the mechanism whereby the larvæ of the clothes moth are able to digest wool. Under his inspiring leadership the Carlsberg Laboratory has fully maintained the fine international reputation which had been handed down by his predecessor, S. P. L. Sørensen.

Prof. Hans Pettersson

WITH his election to the foreign membership of the Royal Society of London, Prof. Hans Pettersson, the well-known Swedish oceanographer, joins six eminent compatriots already in that distinguished company. Born in August 1888, son of Prof. Otto Pettersson, the renowned oceanographer who founded the International Council for the Exploration of the Sea and who died fifteen years ago at the age of ninety-three, Prof. Hans Pettersson has added greatly to the lustre of a family name so closely associated with marine research. After studying physics in Upsala under Knut Angström during 1908–11, he entered upon that period of work in England under Sir William Ramsay which gave him his love of London and his remarkable command of English. In 1914 he became both a doctor of physics of the University of Stockholm and a research associate in oceanography at Gothenburg. Eight years later he was leading a team of workers in the Radium Institute of Vienna in radioactivity and nuclear physics, and it is due to his skill in those fields that he has made such fruitful researches on the radium content of deep-sea sediments and on the rate of their accumulation. The author of numerous papers on oceanographical topics, he became professor of the subject at Gothenburg in 1930 and director of the Oceanographical Institute there in 1939. He is a member of learned societies of many countries and holder of the Patron's Medal of the Royal Geographical Society of London. Pettersson organized and led the highly successful Swedish Deep-Sea Expedition with the *Albatross* during 1947–48.

Dr. Fritz Zernike

THE election of Dr. F. Zernike as a foreign member of the Royal Society is the latest honour he has received in recognition of his distinguished work in physical optics, and in particular for his researches in phase-contrast microscopy. His election follows on the award in 1952 of the Society's Rumford Medal and in 1953 of the Nobel Prize for Physics. Zernike first described the principle of the phase-contrast method in 1933 in a short paper to the twenty-fourth Dutch Physical and Medical Congress; but prior to that his published papers were mainly concerned with the statistical aspects of a variety of physical problems. By extending Abbe's theory of the microscope, he showed both theoretically and experimentally, using apparatus which he had himself constructed, that an image of a phase-grating consisting of transparent lines alternating in thickness could be made visible if the phase of the direct image of the source were changed by 90° relative to the diffracted light. The elaboration of this principle is now well known and forms the basis of the highly successful phase-contrast microscope. Zernike has also carried out important fundamental work on the diffraction theory of optical images, including the effect of small amounts of aberration and of the coherence of the illumination. After being dormant for a period, the subject of microscopy has come very much to life during the past decade, and it is fair to attribute much of this vitality to the stimulus of Zernike's ideas.

Paris Academy of Sciences: Elections

THE following elections have been made in the Paris Academy of Sciences: Prof. P. Tardi, professor of astronomy in the École Polytechnique, Paris, to be a member of the Geography and Navigation Sections in succession to the late Prof. E. de Martonne Prof. A. Vandel, professor of zoology in the University of Toulouse, to be a non-resident member of the Academy in succession to the late Prof. M. Gignoux Prof. H. Lundegårdh, professor of plant physiology in the Agricultural College, Upsala, to be a *correspondant* for the Rural Economy Section in succession to Prof. S. Waksman, recently elected a foreign associate of the Academy; Prof. E. Schmidt professor of mathematics in the Humboldt University, East Berlin, to be a *correspondant* for the Geometry Section in succession to Prof. S. Bernstein recently elected a foreign associate of the Academy Prof. C. Killian, professor of agricultural and experimental botany in the University of Algiers, and Prof. F. W. Went, professor of plant physiology in the California Institute of Technology, to be *correspondants* for the Botany Section in succession to the late Prof. G. Nicolas and the late Prof. P. Becquerel

Leverhulme Research Awards, 1956

THE Leverhulme Trustees have approved th following fellowships and research grants, among others, tenable for periods up to two years, th subject of study being indicated in brackets: *Fellowships:* R. A. Crowson, lecturer in zoological taxonomy, University of Glasgow (young stages and habits of certain primitive endemic Coleoptera in New Zealand); Dr. P. J. C. Dark, Department o Anthropology, University College, London (Mixte ethnohistory: an analysis of the codical art); Dr A. T. A. Learmonth, lecturer in geography, University of Liverpool (land use in the Assam Valley wit special reference to population density and capacity)

Dr. A. I. Richards, formerly director, East African Institute of Social Research, Makerere College, Uganda (changes in the political system of the Bemba of North Eastern Rhodesia, 1935–55); Dr. E. G. Richardson, reader in physics, University of Durham (propagation of sound in a turbulent medium); R. A. Skelton, superintendent of Map Room, British Museum (foundation and early history of the Ordnance Survey, 1782–1825). *Research Grants:* Dr. R. F. Barrow, Fellow of Exeter College, Oxford (spectroscopy of simple molecules); A. R. Bailey, Turner and Newall Research Fellow, Imperial College, London (intercrystalline cracking and failure of high-tensile brass); P. R. Bell, lecturer in botany, University College, London (phylogeny and morphology of the ferns of tropical mountains); Prof. F. Debenham, emeritus professor of geography, University of Cambridge (the Admiralty and the Arctic in the nineteenth century); Lady Drower (a dictionary of the Mandaic language); Dr. K. A. Kermack, lecturer in biological statistics, University College, London (American mesozoic mammals); A. D. Rees, director of extra-mural studies, University College, Aberystwyth (an examination of some of the more important branches of Celtic mythology); H. Thomas, assistant buildings officer, University of Manchester (application of architectural acoustics to the design and construction of schools for the deaf); Prof. D. Williams, professor of Welsh history, University College, Aberystwyth (Benjamin Franklin's circle in London). Further information about the awards can be obtained from the Secretary, Leverhulme Research Awards, St. Bridget's House, Bridewell Place, London, E.C.4.

Royal Aeronautical Society

Honorary fellowship of the Royal Aeronautical Society has been conferred on Sir Roy Dobson and Dr. Hugh L. Dryden. The following awards have been made by the Society: *British Gold Medal for Aeronautics*, to the late Mr. Joseph Smith for his outstanding practical achievements in the design and development of military aircraft; *British Silver Medal for Aeronautics*, to Mr. J. Fenwick for his contributions to the development of air-traffic control systems; *The Society's Gold Medal*, to Sir William Farren for his outstanding contributions to aeronautical research and development (this is the Society's highest honour for work in aeronautics); *The Society's Silver Medal*, to Dr. E. S. Moult for his outstanding contributions to aeronautical engineering and, in particular, for his work in the design of aircraft engines; *The Society's Bronze Medal*, to Mr. J. W. Barnes for his contributions in the field of aircraft instruments; *Wakefield Gold Medal*, to Group Captain W. K. Stewart for his contributions to the design and development of aero-medical equipment; *George Taylor* (*Australia*) *Gold Medal*, to Mr. R. H. Woodall for his paper on some trends in the development of aircraft electrical and starting systems; *Simms Gold Medal*, to Mr. K. V. Diprose for his paper on analogue computing in aeronautics; *R. P. Alston Memorial Prize*, to Mr. D. P. Davies for his practical achievement in the flight testing of prototype civil aircraft; *Edward Busk Memorial Prize*, to Mr. L. E. Fraenkel for his paper on the unsteady motion of a slender body through a compressible fluid; *Herbert Akroyd Stuart Memorial Prize*, to Mr. O. N. Lawrence for his paper on fuel systems for gas-turbine engines; *Usborne Memorial Prize*, to Dr. G. N. Lance for his paper on the lift of twisted and cambered wings in supersonic flow; *Orville Wright Prize*, to Mr. K. W. Gunn for his paper on the effect of yielding on the fatigue properties of test pieces containing stress concentrations; *Branch Prize*, to Mr. W. Tye for his paper on the outlook on airframe fatigue (second Barnwell Memorial Lecture); *Royal Aeronautical Society Navigation Prize*, to Mr. John Grierson for his paper on the evolution of Arctic airways; *Pilcher Memorial Prize*, to Mr. H. Caplan for his paper on the investigation of aircraft accidents and incidents.

Iron and Steel Institute

The following awards have been made by the Iron and Steel Institute: *Bessemer Gold Medal for* 1956, to Dr. C. Sykes (Thos. Firth and John Brown, Ltd.) in recognition of his distinguished contribution to the study of alloy systems, particularly in the field of order–disorder changes and the effect of such changes on the physical properties of alloys; *Sir Robert Hadfield Medal for* 1956, to Mr. H. Morrogh (British Cast Iron Research Association) in recognition of his distinguished contribution to the study of the metallography of cast iron and for researches which resulted in the discovery of nodular iron and the improvement in the quality of cast iron; *Additional Williams Prize for* 1954, jointly to Mr. F. A. Gray and to Mr. S. A. Brooks (Appleby–Frodingham Steel Co., Ltd.) for their paper on an investigation of re-heating furnace design and performance; *Williams Prizes for* 1955, to Mr. A. J. Kesterton (Steel Company of Wales, Ltd.) for his paper on some starting and operating experiences at Abbey melting shop, and to Mr. R. Wilcock (Samuel Fox and Co., Ltd.), for his paper on the operation of a 60-ton arc furnace at Samuel Fox and Co., Ltd.; *Ablett Prizes for* 1955, to Mr. W. Ernest (Samuel Fox and Co., Ltd.) for his paper on waste heat recovery related to the generation of electric power; to Mr. S. R. Phelps (Guest Keen and Nettlefolds, Ltd.) for his paper on electrical requirements of flying shears for bars and billets; and to Mr. R. Stewartson (Guest Keen and Nettlefolds, Ltd.) for his paper on the mechanical design features of flying shears for bars and billets.

Royal Australian Chemical Institute

The following awards have been made by the Royal Australian Chemical Institute: *H. G. Smith Memorial Medal*, 1955, to Prof. R. S. Nyholm, professor of chemistry, University College, London, for his work in inorganic chemistry; *Rennie Memorial Medal*, to Dr. D. R. Stranks, assistant lecturer in radiochemistry, University of Leeds (this Medal is awarded to an Australian chemist less than thirty-one years of age for papers published during the past ten years); *Masson Memorial Scholarship*, 1956, to G. C. Morris, of the University of Sydney, now studying for his M.Sc.

Nuclear Power

The first number of the new journal by Rowse-Muir Publications, Ltd., *Nuclear Power* (1, 1; May 1956; single copy 3*s*. 6*d*., annual subscription £2 2*s*.), has now been published. This journal, designed to "further the development of atomic energy and nuclear techniques for peaceful purposes and in particular to credit British achievements", has an editorial panel of distinguished scientists from British universities and from the U.K. Atomic Energy Authority. Subjects covered in this first number include the methods and plants used for the production of heavy water, dose-rate meters, the production of reactor fuel elements, and the research facilities at the research laboratories of Tube Investments, Ltd., and at the Battelle Institute, Columbus, Ohio. There is also the first of a series of articles on reactor physics by J. F. Hill, of the Reactor School, Harwell. Other sections of the journal consist of editorial comments, news items from various parts of the world, news of equipment used in connexion with nuclear engineering, and abstracts of patents. The remaining section is devoted to reviews of books of use or of interest to the nuclear engineer. Synopses of the articles are given in five languages. These, as well as the contents on the title page, are in type which is unusually small in size. It is stated that forthcoming issues will contain papers, articles and features on nuclear fuel enrichment, fabrication and reprocessing, on reactor design, construction and performance, on the associated power plant, on instrumentation and on isotope production, handling and application to industry.

Courses and Awards in Technology

Details of the award to be given by the recently created National Council for Technological Awards, under the chairmanship of Lord Hives, have been announced. The National Council will grant a diploma in technology, the courses for which will be equivalent in standard to honours degree courses of a British university. The award will be denoted by 'Dip. Tech. (Eng.)' for engineering and by 'Dip. Tech.' for other technologies. There will be two honours classes and a pass level. The courses which will be recognized may be either full-time or sandwich. The minimum time required for a course in a technical college will be three years full-time or four years sandwich course. Students attending full-time courses will be expected to have suitable industrial training amounting in aggregate to not less than one year in industry. The minimum age of admission to courses will normally be eighteen. It should be assumed that the standard of admission to courses will be that of the General Certificate of Education, with two appropriate subjects at advanced level and three subjects at ordinary level, or a comparable standard. Holders of good Ordinary National Certificates, for example, will be eligible; in most other cases National Certificate holders will need additional instruction to qualify for entry to the course. Since the courses are intended for those aiming at becoming professional technologists, they should include a thorough education in the fundamentals of science and technology and their application to development and design. To help fit the students for future responsibilities, the courses must include liberal studies and some instruction in the principles of industrial organization.

Colleges seeking recognition for a course must make formal application to the Council. They will be expected to provide a substantial programme of advanced studies. In particular, the subjects constituting the course must be conducted in an environment where advanced studies are the main preoccupation of the staff. Good library facilities and social amenities are necessary. It is desirable for the college to have residential facilities; but the absence of such facilities will not prevent courses from being recognized at the moment. It is intended, however, to make this a condition as soon as possible. The staff will be expected to be of high quality. In particular, the leaders of each branch of study should have either higher degrees and substantial academic experience, or suitable academic qualifications supported by substantial industrial experience or both. They should also be professionally active in their subjects. It is highly desirable that colleges and industry should arrange their conditions of employment so that interchange of staff for suitable full-time periods can be encouraged. In assessing the staff, the emphasis will be on their intellectual and personal qualities. They should include persons to whom industry would go for advice. Above all, they will be expected to be good teachers and to be able to relate their industrial experience to their teaching work. It is essential that staff engaged on the course should have opportunities for research. Details of the procedure for applying for the recognition of suitable courses and the fees to be charged for the courses will be announced later.

Permanent Commission of the International Fisheries Convention

The fifth meeting of the Permanent Commission set up under the International Fisheries Convention of 1946 took place in London during May 8–11. Delegations attended from all thirteen of the member governments, namely, Belgium, Denmark, the Federal German Republic, France, Iceland, Ireland, the Netherlands, Norway, Poland, Portugal, Spain, Sweden and the United Kingdom of Great Britain and Northern Ireland. Observers were present from the Union of Socialist Soviet Republics, which was represented for the first time. There were also observers from the International Council for the Exploration of the Sea, the Food and Agriculture Organization of the United Nations, and the International Commission for the Northwest Atlantic Fisheries. Much of the Commission's discussion was devoted to the report of an *ad hoc* scientific committee set up at the previous meeting to review available information and to advise the Commission on minimum mesh sizes and minimum size-limits for fish, and to say whether any changes were required. This report is to be published, and it was agreed to recommend that the member governments should have it translated and should seek the views of their own fishing industries, and should report back with their recommendations and proposals by December 31, 1956. Meanwhile, the 75-mm. minimum mesh for ordinary trawls will be continued until April 4, 1958. The Commission also gave further attention to the problem of mixed fishing for protected and for other species. The Commission appointed a Committee composed of representatives of the six countries most concerned, namely, Belgium, France, the Netherlands, the Federal German Republic, Poland and Sweden, to study this problem further for the next meeting. Finally, the Commission received reports from the International Council for the Exploration of the Sea on the question of a definition of the light trawl, and the problem presented by the capture of undersized whiting in the industrial fisheries. No further action is to be taken at present on these problems since the International Council is continuing its investigations. Klaus Sunnanaa (Norway) was elected president for the next three years in succession to R. G. R. Wal (United Kingdom), whose term of office had expired and A. Alloy (France) was elected vice-president in succession to Dr. G. Rollefsen (Norway). The Commission will hold its next meeting in London beginning on May 14, 1957.

K. W. Feuerbach and his Geometrical Research

One of the most important theorems of the geometry of the triangle that was developed during the nineteenth century is the one which shows that the nine-point circle of a triangle is tangent to the inscribed and to each of the three escribed circles of the triangle. The theorem was discovered and first proved by Karl Wilhelm Feuerbach, a little-known mathematician who led a short and tempestuous life; an account of his life and researches has been given by Prof. Laura Guggenbuhl (*Scientific Monthly*, 81, No. 2; 1955). Feuerbach's proof was purely algebraic, being modelled upon the proof in an article by Euler in 1765; but while it is in principle simple enough, the detail of the working is exceedingly laborious, and in succeeding years many people, fascinated by the difficulties in Feuerbach's proof, seemed to find it a pleasant challenge to produce a different and simpler one. Feuerbach, the third son of a family of eleven, was born in Jena in 1800, his father being a successful lawyer. Shortly after the publication of his book, Feuerbach, only twenty-two years old and without previous teaching experience, was appointed professor of mathematics at the Gymnasium at Erlangen. Soon afterwards, he studied for a time at the University of Freiburg under Karl Buzengeiger, who is credited with having had a great influence upon the young mathematician. On returning to Erlangen, however, he was involved in political troubles and was arrested. At his trial he was acquitted; but he spent more than a year in prison awaiting trial, and during this time he commenced some further mathematical research. This was later completed, and was the subject of a review by Cantor in the *Sitzungsberichte der Heidelberg Akademie der Wissenschaften*; in a final summary, Cantor says that Feuerbach in this work proved himself to be an independent co-discoverer with Mobius of the theory of the homogeneous coordinates of a point in space. At the time of his imprisonment, Feuerbach was already showing signs of mental derangement, and by 1828 this was so serious that he had to retire from teaching. He died six years later when not yet thirty-four.

Mycological Collections in Latin America

The attention of mycologists is directed to the Second General Catalogue of Latin American Mycological Collections, published under the auspices of the Unesco Centre for Scientific Co-operation (Centro de Cooperación Cientifica para América Latina de la U.N.E.S.C.O., Bulevar Artegas 1320, Casilla de Correos 859, Montevideo, Uruguay; 1955). Indications are given of all the fungi in the collection and of the institutions or laboratories where they are maintained. Full information on the origin, biological properties and characteristics of the cultures, biographical citations, etc., can be obtained on application to the Centro de Cooperación.

The United States National Museum

The annual report of the United States National Museum for 1955 records the opening of the First Ladies Hall on May 24, 1955. The eight display units in the Hall are designed to represent different rooms in the White House, Washington, from the earliest period to the present time and contain architectural details acquired from the House during its recent reconstruction. They give the public an opportunity to view the dresses in surroundings similar to those in which they were originally worn. Each room contains three to six dresses representing a time of about twenty years. The changing styles in White House decoration shown in these rooms are based on available drawings and photographs together with written descriptions.

Royal Society Depository of Unpublished Mathematical Tables

The following is a list of accessions to the Royal Society's depository of unpublished mathematical tables since the publication of the last list in *Nature* (175, 712; 1955): (52) Étude de $3n^2 + 1$, $3n^4 + 1$, $3n^8 + 1$ (A. Ferrier); (53) Table of $\mathrm{Bi}'(+x)$, for $x = 0(0{\cdot}01)2$ and $\mathrm{Hi}'(-x)$, for $x = 0(0{\cdot}01)10$ (K. I. McKenzie and M. Rothman); (54) Table of a function related to the error function (H. J. Gawlik); (55) Étude de $5n^2 - 1$, $5n^4 - 1$ (A. Ferrier); (56) The self-consistent field for Zr^{4+}: supplementary tables (S. L. Altmann); (57) Tables for the regular reflexion of plane shocks in air (C. K. Thornhill and Katharine M. Stocks); (58) Tables of quantities associated with oblique shocks in air for which the flow deflexion is a maximum or behind which the flow is sonic (C. K. Thornhill and Katharine M. Stocks); (59) Tables of Sievert's integral (S. Johnston); (60) Solutions of the Poisson–Boltzmann equation for two equal spherical colloidal particles (N. E. Hoskin); (61) Tables of Fresnel integrals (J. R. Airey). Further information about these tables can be obtained from the Assistant Secretary, Royal Society, Burlington House, London, W.1.

International Union of Forest Research Organizations: Congress at Oxford

The twelfth Congress of the International Union of Forest Research Organizations is to be held in Oxford during July 7–14 and will be followed by organized tours in various parts of Britain. It is expected that nearly two hundred delegates from twenty-five countries, mainly European but including Canada, Australia, New Zealand, the United States and Japan, will take part. The previous Congress was held in Italy in 1953. The Union was founded as long ago as 1890, and its aims include the establishment of close personal relations between forest research workers of all countries, particularly between specialists working in the same field of activity. The meetings at Oxford will be under the following main headings: general forest influences; forest production; establishment and maintenance of forests; forest economics—operational efficiency; and forest products. The Congress is to be opened at Regent's Park College, Oxford, on July 7, by the Minister of Agriculture, Mr. Heathcoat Amory, and during the week-end there will be local tours for delegates. In the ensuing week, meetings of the Congress will be held at the Imperial Forestry Institute and there will be a closing plenary session on July 14 in Regent's Park College. On July 12 excursions will be available to the Forestry Commission's Research Station at Alice Holt Lodge, near Farnham, Surrey; the Forest Products Research Laboratory at Princes Risborough; and the Rothamsted Experimental Station, Harpenden. Following the Congress, there will be seven separate tours—three in England, three in Scotland and one in Wales—and the programme will include visits to Forestry Commission areas and a number of private estates known for their outstanding forestry.

Announcements

PROF. ARTHUR HOLMES, regius professor of geology in the University of Edinburgh, has been awarded the Penrose Medal for 1956 of the Geological Society of America. The Medal is awarded, on occasion, in recognition of outstanding original contributions or achievements which mark a decided advance in the science of geology.

SIR HARRY JEPHCOTT has been appointed chairman of the Advisory Council of the Department of Scientific and Industrial Research in succession to Sir Hugh Beaver, who has resigned; Sir Hugh will continue to serve as a member of the Council.

DR. R. A. WILKINS, vice-president, research and development, of the Revere Copper and Brass, Inc., Rome, New York State, has been elected a Fellow of the Institute of Metals in recognition of his outstanding services to the Institute, and in particular as corresponding member to the Council in the United States. Fellowship of the Institute is limited to twelve, and Dr. Wilkins is the first member resident outside the British Isles to be elected.

THE official title of the Commonwealth Bureau of Dairy Science at Shinfield, Reading, has been changed to the Commonwealth Bureau of Dairy Science and Technology. It is felt that this will reflect more accurately the scope of the Bureau's activities.

A SUMMER laboratory course on techniques and applications of the electron microscope will be held during June 11–23 in the Department of Engineering Physics of Cornell University. The course will be on the lines of those held in previous years. Further information can be obtained from Prof. Benjamin M. Siegel, Department of Engineering Physics, Rockefeller Hall, Cornell University, Ithaca, N.Y.

A SUMMER school in programme design for automatic digital computing machines will be held in the University Mathematical Laboratory, Cambridge, during September 17–28. The course will be along the same lines as those held in previous years. Application forms, to be returned by June 15, and further information can be obtained from the secretary of the Board of Extra-Mural Studies, G. F. Hickson, Stuart House, Cambridge.

THE annual course on tropical hygiene for laymen will be held by the Ross Institute this year during July 16–20. The course is intended for those whose work in the tropics makes them responsible for the health and welfare of others. There is no fee. Further information can be obtained from the organizing secretary, L. G. Ponsford, Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, Keppel Street (Gower Street), London, W.C.1.

THE sixth summer school on welding, organized by the British Welding Research Association, will be held at Ashorne Hill, near Leamington Spa, Warwickshire, during June 18–23. After a general introduction, the course will be divided into four separate groups dealing with the following topics: gas-shielded welding; resistance welding; metallurgy and physics of welding; and inspection, testing and quality control in welding processes. Application forms and further information can be obtained from the Organizing Secretary, Sixth Summer School of Welding, B.W.R.A., 29 Park Crescent, London, W.1.

A JOINT Committee of the Field Studies Council and the Royal Meteorological Society is again arranging a short vacation course in meteorology, which will be held at Malham Tarn Field Centre, near Settle, Yorks, during August 22–29. The course will be directed by Mr. C. D. Ovey, University lecturer in geography, Cambridge, and Dr. R. S. Scorer, University lecturer in meteorology, Imperial College of Science and Technology, London. The main emphasis will be on practical aspects of meteorology. The inclusive fee for the course is £7. Particulars can be obtained from the Publicity Secretary, Field Studies Council, Ravensmead, Keston, Kent.

APPLICATIONS are invited by the Atomic Energy Research Establishment, Harwell, from physicists and electronic engineers holding a degree or equivalent qualification, who wish to attend the eleventh specialized course, during June 11–15, on the design, use and maintenance of electronic instruments used in nuclear physics, radiochemistry, and in work with radioisotopes. Attendance at the course is limited to twelve; the syllabus will include lectures and practical work concerned with counters, d.c. and pulse amplifiers, coincidence units, scalers and ratemeters, and the lecturers and demonstrators will be specialists from the Atomic Energy Research Establishment. The subject will be entirely non-secret. The fee for the course is 15 guineas, and living accommodation can be arranged locally at a charge of four guineas approximately. Application forms can be obtained from the D.A.O., Electronics Division, A.E.R.E., Harwell, Didcot, Berkshire. These must be returned by May 25.

THE Sixth International Mechanical Engineering Congress will be held in Paris during June 4–9, the subject for discussion being "Surface Treatment for the Improvement of Mechanical Properties and Protection against Corrosion". The following topics will be considered: improvement of resistance to wear by increase of surface hardness; improvement of resistance to wear through improvement of friction characteristics; improvement of resistance to heat; improvement of resistance to corrosion by metal coatings deposited by means other than electroplating; improvement of resistance to corrosion by electroplating processes; improvement of resistance to corrosion by chemical processes; improvement of resistance to corrosion by non-metallic coatings; and surface treatment for decoration and for improving optical properties. The official languages of the meeting will be English, French and German. Further information can be obtained from the Permanent Secretariat of the 6th I.M.E.C., 11 avenue Hoche, Paris 8^{e}.

THE second annual Guenter Loeser Memorial Lecture of the Geophysics Research Directorate of the Air Force Cambridge Research Center will be given this year by Dr. Robert G. Breene, jun., speaking on the "Phenomenological Considerations of the Interruption Theory of Line Broadening". The lecture will be delivered on June 29 in the Charter Room of the New England Mutual Building, Boston, Mass.

THE Central Laboratories for Scientific and Industrial Research, Hyderabad, have been formally taken over by the Council of Scientific and Industrial Research, Government of India, and will henceforth be known as the Regional Research Laboratory, Hyderabad. This is the first regional laboratory of the Council. Dr. S. Husain Zaheer remains as director, and the research staff will continue as before.

FUEL IN INDIA

By the late PROF. M. N. SAHA, F.R.S.

THE relative contributions of different types of fuels to the total energy production in India has received attention from many quarters in recent years[1–4]. Unfortunately the statements made are often contradictory; in this article I shall try to clear up this confusion.

By 'fuel' I mean anything which gives energy on combustion: coal, oil, wood, cattle dung, dried twigs and leaves. Other energy-producing agencies are nuclear fuel, which has not yet been used in India, and hydroelectricity. To compare the relative contributions of the different types of fuels to the total fuel economy of India, we have to know the absolute calorific value of each type of fuel.

The absolute calorific value of a fuel is the amount of heat given off on its complete combustion. This is listed for various types of fuels in Table I[5].

Table 1

Fuel	Calorific value (k.cal./lb.)
Soft coke	2,550
Hard coke	2,850
Charcoal	3,500
Wood (dry)	2,000
Dry leaves	1,500–2,000
Cow-dung (sun-dry)	1,500
Petroleum products (average)	4,460

Coal. The coal production in India in 1952 was 35 million tons. This was distributed among the consumers as follows[3]:

Table 2

Consumer	Amount consumed	Percentage
Railways	11·5 million tons	32·8
Iron and steel	4·0 ,, ,,	11·4
Collieries	2 0 ,, ,,	5·7
Steam and electric utilities	2 5 ,, ,,	7·15
Brick, cement, potteries, refractories and lime kilns	3·0 ,, ,,	8·6
Mills, works, etc.	3·0 ,, ,,	8·6
Bunker and export	3 5 ,, ,,	10·0
Other industries	2 5 ,, ,,	7·15
Domestic	3 0 ,, ,,	8 6

From Table 2, it can be seen that less than 10 per cent of coal in India is used as domestic fuel, so that more than 90 per cent of coal burnt is used by industries.

Petroleum products. The total amount of petroleum products imported into India in 1952 was 3·3 million tons, while the indigenous production was only 0·22 million tons; so the total was 3·5 million tons, which has a calorific value of 35×10^{12} k.cal. (see ref. 3). From Table 1, it can be seen that the equivalent amount of coal giving the same energy as the petroleum products in India per annum would be about 6 million tons.

Hydroelectricity. Total output of hydroelectric power in India was about 2,000 million kWh.[3], which is equal to $1 \cdot 72 \times 10^{12}$ k.cal. Assuming 30 per cent efficiency for the conversion of heat energy into electrical energy in a modern thermal station, the above amount of electrical energy should be equivalent to the burning of about 1 million tons of coal.

Cattle dung. Cattle dung is an important domestic fuel in India, though there is a good deal of controversy about its relative contribution to the fuel economy of the country. We can estimate the total amount of energy derived by burning cattle dung in the following manner. The cattle population (which includes cows as well as buffaloes), according to the Report on the Marketing of Cattle in India (1946)[6], was 212 million in undivided India. Taking the cattle population to be three-fourths of this number after partition, India should have now about 160 million. This is in agreement with the figure of 177·4 million published in the Draft Outline of the First Five Year Plan, published by the Planning Commission (1951)[7].

According to the Report on the Marketing of Cattle in India[6], the average Indian cow (adult) produces about 25 lb. of green dung a day, whereas the young cow produces about 18 lb. a day. The contributions of the adult and young buffaloes are 60 lb. and 40 lb. a day respectively, as given in the above report.

The actual fuel value of cow-dung can then be calculated from the data given above. Assume that of the 180 million head of cattle, 140 million are cows and 40 million are buffaloes, and that the percentages of adult and young among cows and buffaloes are 70 per cent and 30 per cent. Then the amount of dung produced by 140 million cows is approximately $100 \times 25 + 40 \times 18 = 3{,}220$ million lb. per day. Similarly, the amount of dung produced by 40 million buffaloes is approximately $30 \times 60 + 10 \times 40 = 2{,}200$ million lb. per day. Hence, the total amount of dung produced is $\frac{3{,}220 + 2{,}200}{2{,}240} =$ 2·42 million tons per day, say 890 million tons a year.

Now according to the Memorandum on the Development of Agriculture and Animal Husbandry in India (1944)[8] published by the Advisory Board of the Imperial Council of Agricultural Research, only 40 per cent of the total green dung is used as fuel, 40 per cent is used as manure and the remainder is lost. Actually there is some difference of opinion on the percentage of dung used as fuel. Thus the Report of the Expert Committee on Manures and Fertilizers (1953)[9] published by the Ministry of Food and Agriculture, Government of India, gives 50 per cent, whereas according to W. Burns, an officer on special duty in the Department of Education, Health and Lands of the Government of India (1944)[10], this figure should be 66·6 per cent. Here I accept the figure 40 per cent as more reliable. Hence total green dung used as fuel is $890 \times 0 \cdot 4 = 356$ million tons. Again, according to the above Memorandum (1944), 1 lb. of dried cow-dung comes from about 5 lb. of green cow-dung. So the equivalent weight of dried dung is $\frac{356}{5} = 71$ million tons.

Now, if the whole combustible material in dried cow-dung is fully burnt, about 1,500 k.cal. of heat per lb. of dried cow-dung is obtained[5]. But the calorific value of 1 lb. of coal is much higher, being in the range of 2,550–2,850 k.cal./lb. for Indian coal. The average may be taken to be about 2,700 k.cal./lb. Hence for complete combustion 1 lb. of coal gives as much heat as 1·8 lb. of dried cow-dung. Thus the contribution of cow-dung fuel to the fuel economy of India is equivalent to 40 million tons of coal.

Fuel wood. The position with respect to fuel wood is not very clear. Recorded figures of fuel wood consumption from lands classified as forests indicate an extremely low value, being only about 53 lb. per head per year. According to the President of the Forest Research Institute and Colleges, India, this is a ridiculously low figure (private communication). However, there are reasons for believing that unauthorized wood-cutting amounts to many times the recorded figures, and that leaves and twigs are also utilized as fuel[3]. Actually, some idea regarding the amount of domestic fuel wood burnt annually in India may be obtained in the following manner.

According to Lahiri and Das Gupta[3], the average per capita energy consumption in India amounts to about 80–100 therms per year, which is equivalent to about $2,800 \times 10^{12}$ to $3,500 \times 10^{12}$ B.T.U. a year for the entire population. Of this, about $1,100 \times 10^{12}$ B.T.U. a year is met from coal, oil and hydroelectricity. The remainder must therefore come from wood fuel and farm waste. The energy obtained from these sources must therefore be in the range of $1,700 \times 10^{12}$ to $2,400 \times 10^{12}$ B.T.U. We may therefore assume that about $2,000 \times 10^{12}$ B.T.U. or 500×10^{12} k.cal. of energy are obtained in India per annum by burning wood fuel and farm waste[2,3]. Taking the heating value of 40 million tons coal-equivalent of cattle dung to be about 242×10^{12} k.cal., the heating value of fuel wood should be about 258×10^{12} k.cal., that is, equivalent to 43 million tons of coal approximately. This would bring the per capita consumption of fuel wood in India to about 370 lb. per head per year, which is about seven times the figure quoted above.

Table 3

Fuel	Coal equivalent in million tons consumed annually	Percentage contribution to the fuel economy of India
Coal	35	28·0
Oil and hydroelectricity	7	5·6
Cattle dung	40	32·0
Wood, dried leaves and twigs	43	34·4

We are now in a position to estimate the percentage contribution of different types of fuels to the fuel economy of India. This is shown in Table 3.

THE U.S. NATIONAL ACADEMY OF SCIENCES

ANNUAL MEETING

THE ninety-third annual meeting of the National Academy of Sciences was held in Washington, D.C., during April 23–25. At the annual dinner on April 24, there were two guests of honour: Dr. Alexander von Muralt, past president of the International Council of Scientific Unions, and now president of the National Research Council of Switzerland and rector of the University of Berne; and Dr. John E. Burchard, dean of the School of Humanities and Social Studies at the Massachusetts Institute of Technology, and president of the American Academy of Arts and Sciences. Thirty-four papers were read at five sessions, and, in addition, three other sessions were devoted to symposia on the following subjects: solar and terrestrial relationships; biomolecular organization and life processes; and science in education.

At the meeting the following awards of the Academy were presented: *Agassiz Medal*, to Prof. Alfred C. Redfield, associate director of the Woods Hole Oceanographic Institution; *Henry Draper Medal*, to Prof. Hendrik C. van de Hulst, professor of theoretical astronomy in the University of Leyden; *Elliot Medal*, to Prof. Archie Carr, professor of biological sciences in the University of Florida; *Kimber Genetics Award*, to Prof. Sewall Wright, professor of genetics in the University of Wisconsin; *Kovalenko Medal*, to Dr. Peyton Rous, member of the Rockefeller Institute for Medical Research; *Thompson Medal*, to Prof. Alfred S. Romer, Alexander Agassiz professor of zoology and director of the Museum of Comparative Zoology, Harvard University; *Watson Medal*, to Dr. Chester B. Watts, director of the Six-Inch Transit Circle Division, United States Naval Observatory.

The Agassiz Medal of the Academy, which is awarded for distinguished work in oceanography, goes to Dr. Redfield in recognition of his many and diverse contributions in this field. He has been associated with the Woods Hole Oceanographic Institution since 1931 and has been professor of physiology in Harvard University since the same date. His knowledge of physiology, a field in which he made important contributions before turning to the study of the sea, coupled with his interest in sailing and the seashore, has been an important part of his work in oceanography. For example, he translated the physiological functions of blood into the metabolism of the marine environment in which water and organisms interact as an entity with a physiology of its own. His analyses of biochemical cycles in the sea, of the origin and distribution of organisms, and of the products of biological activity have led to interpretations of the oceanic circulation which incorporate the physical, chemical and biological cycles. Lately he has been studying the development and growth of salt marshes and the genesis and propagation of waves associated with hurricanes.

The Draper Medal, which was established to recognize significant contributions to astronomical physics, has been awarded to Prof. van de Hulst for his noteworthy contributions to the field of radio astronomy and in particular for his prediction, made in 1944, that radiation of 21 cm. wave-length should be emitted by neutral hydrogen in interstellar space.

The probability of the transition in a given atom is extremely low; but because the total quantity of hydrogen in the vast reaches of interstellar space is enormous, detectable amounts of the radiation are emitted. In 1951 observers in the United States, Australia and the Netherlands detected the radiation independently as a sharp line in the radio-frequency spectrum. Because of its sharpness, the line is useful for the determination of the velocities at which the clouds of hydrogen are moving towards us or away from us, and because radiation at this frequency penetrates regions relatively opaque to visible light, the observations have contributed much to the great new fund of knowledge that comes from the rapidly growing field of radio astronomy. Soon after his prediction was confirmed by observation, Prof. van de Hulst, in collaboration with Jan Oort and C. A. Muller, began to study the hydrogen radiation around the equator of our galaxy, and by 1953 they had produced evidence of the spiral structure of the galaxy in striking agreement with observations by other means.

The award of the Daniel Giraud Elliot Medal has been made to Dr. Carr in recognition of his book, "Handbook of Turtles: the Turtles of the United States, Canada, and Baja California" (Comstock Publishing Associates, Cornell University Press, 1952). Dr. Carr has devoted a number of years in the field and the laboratory to the study of the anatomy and zoology of the turtle, and his "Handbook" is an account of all kinds of turtles found in the area north of Mexico, but including Lower California. After discussing the probable evolution of the turtle group with a summary of physiology, adaptation, anatomy and economic value, he describes the various kinds of turtles and their distribution, their appearance being illustrated by many excellent photographs and drawings. The Elliot Medal has been awarded by the Academy annually since 1917, under a provision of the will of Daniel Giraud Elliot expressing his wish to provide a medal and honorarium to the author of any paper, essay or other published work of outstanding merit in zoology or palæontology.

Prof. Wright, the recipient of the Kimber Genetics Award, has made important contributions to both theoretical and experimental genetics. His early experimental work was concerned with the effects of inbreeding in animals, and this led to studies on the relative importance of heredity and environment as causes of variation. His later work has dealt with the problems of physiological and developmental genetics, and, using guinea pigs, he has analysed the complex and remarkable interaction effects of genes. In theoretical genetics, Prof. Wright is perhaps best known for his series of mathematical papers on various aspects of evolution. His theoretical work on the statistical consequences of Mendelian heredity, although directed primarily to the problem of evolution, has had profound effects on the methods by which domestic plants and animals are genetically improved.

The award of the Kovalenko Medal to Dr. Rous is in recognition of his distinguished contributions in the field of experimental medicine. Very early in his career he observed an association between viruses and tumour growth. Because he was so far in advance of his field, working at a time when knowledge of viruses was meagre and cancer research was in its infancy, the significance of this relationship was not at first recognized. For the past two decades he has been actively concerned with the viral etiology of tumours. He has also worked on the physiology and pathology of the liver and the physiology of the blood vessels. In addition, he has been editor of the *Journal of Experimental Medicine* for many years. The Kovalenko Medal was established in 1949 by Dr. M. S. Kovalenko in memory of his wife, Jessie Stevenson Kovalenko, for outstanding contributions to medical science, and Dr. Rous is the second recipient.

Prof. Romer, the recipient of the Thompson Medal, has spent most of his research career studying the comparative anatomy and evolution of vertebrate animals. His speciality has been the reptilian and amphibian life of the Permian period, some 200–225 million years ago, soon after the vertebrates in the course of their evolution had emerged from the water and as their conquest of the land was getting well under way. In this connexion he has shown that the ancestral freshwater fishes already had lungs and other pre-adaptations for land life, and has developed the theory that legs, capable of walking on land, were originally an adaptation for staying in the water. They permitted the ancestral fishes to wriggle from a drying pool across land to other pools still holding water in seasons of drought. Especially noteworthy are his intricate studies of details of the brain-case and reconstruction of vanished nerves in fishes, amphibians and reptiles long extinct. Prof. Romer has himself discovered and collected many of the rare fossil animals that he has studied; he has led many fossil-hunting expeditions, especially in Texas.

Dr. Watts, who receives the James Craig Watson Medal in recognition of his outstanding contributions to astronomical research, has spent the greater part of his forty-five years at the United States Naval Observatory, determining positions of the Sun, Moon, planets and stars; and since 1934 he has been chiefly responsible for the six-inch transit circle, and with a judicious combination of mechanical, optical, photographic and electronic techniques, he has brought the instrument to an extremely high state of perfection. He has recently designed and supervised the construction of a new nine-inch transit circle at the Observatory. The precision of all these measurements is based on observations of the edge of the Moon's disk, and the edge is always irregular because of the high mountains and low valleys on the Moon's surface and also because a slightly different aspect of the edge is seen from time to time. About eleven years ago, Dr. Watts undertook to survey that part of the Moon's surface (comprising some 18 per cent) which is seen as an edge. To survey a surface a quarter of a million miles away to an accuracy of fifty feet required some thousand photographs, the invention and construction of an automatic photoelectric machine for tracing the profile of each photograph and drawing it on a strip of paper 30 ft. long, the design and construction of analogue computers for analysing the profiles and translating them into numerical form, the devising of means for integrating the profiles into a representation of the surface of the Moon in the vicinity of the edge, and finally the development of the most readily usable form for publication of the results. The survey is now complete and will be published shortly.

The following new elections were made to the Council of the Academy: *Treasurer*, Dr. William J. Robbins, director of the New York Botanical Garden, New York (this being the second such term of office for which he has been elected treasurer); *Members of Council*, Prof. I. I. Rabi, professor of physics, Columbia University, New York, and Dr. F. E. Terman, dean of the School of Engineering, Stanford University, Stanford, Calif. The other officers of the Academy, who were elected in previous years and will continue until expiry of their terms of office, are as follows: *President*, Dr. Detlev W. Bronk; *Vice-President*, Dr. George W. Corner; *Home Secretary*, Dr. Hugh L. Dryden; *Foreign Secretary*, Prof. John Gamble Kirkwood; *Members of Council*, Prof. Farrington Daniels, Dr. E. A. Doisy, Dr. James Gilluly, Dr. Theophilus S. Painter, Dr. Merle A. Tuve and Prof. Edwin B. Wilson.

The following have been elected members of the Academy: G. von Békésy, senior research Fellow in psychophysics, Harvard University; M. Benedict, professor of nuclear engineering, Massachusetts Institute of Technology; K. E. Bloch, professor of chemistry, Harvard University; K. S. Cole, director of the Laboratory of Biophysics, National Institute of Neurology, Diseases, and Blindness, National Institutes of Health, Bethesda; B. L. Crawford, jun., professor of physical chemistry, University of Minnesota; W. A. Fowler, professor of physics, California Institute of Technology; C. P. Haskins, president of the Carnegie Institution of Washington; E. W. Haury, professor of anthropology, University of Arizona; P. Kusch, professor of physics, Columbia University; A. L. Lehninger, professor of physiological chemistry, School of Medicine, Johns Hopkins University; M. G. Mayer, senior physicist, Argonne National Laboratory, Lemont; C. P. Miller, professor of medicine, University of Chicago; W. W. Morgan, professor of astronomy, Yerkes Observatory, University of Chicago; W. H. Munk, professor of geophysics, Scripps Institution of Oceanography, La Jolla; M. S. Newman, professor of chemistry, Ohio State University; R. F. Pitts, professor of physiology, Cornell University College of Medicine; J. D. Roberts, professor of organic chemistry, California Institute of Technology; K. P. Schmidt, emeritus curator, Department of Zoology, Chicago Natural History Museum; M. Schwarzschild, professor of astronomy, Princeton University; C. E. Shannon, research mathematician, Bell Telephone Laboratories, Inc.; F. K. Skoog, professor of botany, University of Wisconsin; N. E. Steenrod, professor of mathematics, Princeton University; W. H. Stockmayer, professor of physical chemistry, Massachusetts Institute of Technology; A. Szent-Györgyi, director of research, Institute for Muscle Research, Inc., Marine Biological Laboratory, Woods Hole, Mass.; C. H. Townes, professor of physics, Columbia University; F. J. Turner, professor of geology, University of California, Berkeley; J. Verhoogen, professor of geology, University of California, Berkeley; M. B. Visscher, professor of physiology, University of Minnesota; J. C. Warner, president of the Carnegie Institute of Technology, Pittsburgh; W. H. Zinn, director of the Argonne National Laboratory, Lemont.

The following have been elected foreign associates of the Academy: Prof. F. G. Gregory, director of the Research Institute of Plant Physiology and professor of plant physiology, Imperial College of Science and Technology, London; Sir K. S. Krishnan, director of the National Physical Laboratory, New Delhi; Prof. A. E. Michotte, professor of psychology, University of Louvain; and Prof. J. J. C. Pérès, dean of the Faculty of Sciences and professor of rational mechanics, University of Paris.

FORESTRY COMMISSION

REPORT FOR 1954

THE annual report of the Forestry Commission for 1954* opens with a statement on the unveiling of a memorial on the site in Keilder Forest where the ashes were scattered of the late Lord Robinson, chairman of the Forestry Commission during 1932–52 and a member of the Commission from its inception.

The year 1954 marks the peak of the Commission's planting so far, a total of 70,400 acres having been achieved, or 2,800 acres more than the previous year. Since the end of the Second World War the rate of annual planting has been increased each year up to this major total. The regular increase, it is noted, has only been maintained by materially reducing the reserves of land awaiting planting. So the point has been reached when the annual planting programme will not only not increase but will in fact fall. The report states that the planting to be carried out in 1955 will bring the planted forest area under the Commission up to and beyond the million acres mark: a truly remarkable and meritorious performance, with all the difficulties and setbacks the Commission has had to face since its inception in 1920, when five million acres of forests were aimed at. More land is required; but the problem is not merely one of acquiring land, for it must be suitably distributed plantable land. There are still large tracts of country running into many hundreds of thousands of acres the best use of which is undoubtedly forestry. It is this type of land which the Commission wishes to acquire if the owners are unable to plant it themselves. Private planting continues to rise steadily though surely: including areas planted without grants, a total of 19,100 acres were planted—nearly a thousand acres more than the previous year.

The production and consumption of home timber were the same as during 1953. The cut in hardwood species was probably less, due to the poorer quality of the timber now being felled and to the abolition of softwood consumer licences in November 1953. It is interesting to note that the expensive home-grown programme inaugurated in 1919 is now beginning to show a financial return, in the pulp and pitwood markets, though difficulties with reference to mining timber and its testing for quality are still under debate. The big Scottish windblow of January 1953 has continued to provide large amounts of timber, of which the National Coal Board has taken advantage. The large intake of home pit-props by the English collieries has been due to an increase in normal production—a most satisfactory position in view of the fact that at the beginning of the century, and before and after, the mines were dependent on Scandinavian and other imports at great cost. Nevertheless, only about one-quarter of the estimated consumption of Britain as a whole is being supplied from home sources.

An interesting investigation is in the possible utilization of inferior and poorly grown hardwoods for wood pulp. The main bulk of these hardwoods are to be found in the south of England, and two British paper-making groups are considering the question of ground wood-pulp for newsprint and

"Kraft" pulp for wrapping and packaging. It is said that the requirements of the raw materials for such processes are less exacting in quality and quantity than in the case of dissolving pulp, which is largely used in the manufacture of artificial fibre.

Progress continued in the dedication of woodlands, and during the year the area dedicated increased from 225,000 acres to 343,000 acres.

AUSTRALIAN ATOMIC ENERGY COMMISSION

A REPORT of the work of the Australian Atomic Energy Commission since its establishment in 1953 is outlined in an article by Prof. J. F. Baxter, vice-chancellor of the New South Wales University of Technology, in the *Australian Journal of Science* (17, No. 5, 151; 1955). Details are given of the initial stages which led up to the establishment of the Commission, its composition and its two main fields of activity, namely, that related to the discovery and production of uranium and that related to the development of the use of atomic energy for industrial and other purposes. In surveying what the Commission has accomplished since its establishment, Prof. Baxter mentions the completion of the plant for the mining of uranium ore at Rum Jungle, which was set in motion by the Prime Minister on September 17, 1954, and of the opening of the Radium Hill mine and concentrator during 1954. A modern treatment plant at Port Pirie was expected to be completed in the near future.

In regard to its responsibilities for the development of uses for atomic energy, the Commission decided to try to obtain access to the large amount of secret information accumulated by Great Britain, the United States and Canada, and to work in partnership with these powers. After various discussions and visits by prominent scientific workers both from Great Britain to Australia and vice versa, Britain offered to give to Australia its accumulated knowledge arising from its industrial atomic-energy programme and, in addition, agreed to enter into a co-operative research programme with Australia whereby the Australian Atomic Energy Commission would set up a research and development organization in Australia while Britain would provide facilities for the training of Australian scientists and engineers in the various British atomic-energy establishments. Accordingly, a Scientific Advisory Committee, consisting of Prof. M. Oliphant, Prof. L. H. Martin, Dr. F. W. G. White, Prof. R. Myers, Prof. T. G. Hunter, Prof. J. S. Anderson, Mr. V. Brain and Prof. J. P. Baxter (chairman), was appointed by the Commission, and a comprehensive group of laboratories has been constructed and equipped on a site some twenty miles south of Sydney.

A large research reactor of a modern type, designed to give a high neutron flux, is to be installed; and a scientific staff of fifty senior scientists and about three hundred other personnel are to be recruited. The chief of research and development is Prof. C. N. Watson-Munro; the chief engineer and deputy chief of research, Prof. G. C. J. Dalton; and Dr. G. L. Miles and Mr. K. F. Alder, leaders of the chemistry and metallurgy departments, respectively. In addition, the initiation and support, on a very large scale, of research and development work in the Australian universities is planned by the Commission, and special facilities for research and advanced training for engineers and scientists from universities and industry in its laboratories at Sydney are to be provided. Finally, a Business Advisory Group has been formed by the Minister for Supply in order that the Commission and leaders of industry may confer closely and regularly on atomic energy matters.

THE TUBER-BEARING SPECIES OF *SOLANUM*

MUCH has been written of the potato, its South American origin, its introduction into Europe, its many varietal forms and its taxonomy. J. G. Hawkes (*Proc. Linn. Soc.*, 166, 1 and 2, 97; 1956) has now contributed a comprehensive and critical taxonomic study of the tuber-bearing species of *Solanum*, special attention being paid to *S. tuberosum* and the tetraploid species complex. In the designation of a nomenclatural type for *S. tuberosum* the early descriptions of C. Bauhin, Clusius and others are mentioned in relation to those of Linnaeus. Evidence is brought forward to show that one of the three specimens in the Linnean Herbarium labelled as *S. tuberosum* may be considered as the lectotype. It is then pointed out that Linnaeus's description, made when one species of tuberiferous *Solanum* alone was known, could equally well be taken as referring to some 80 per cent of the wild species described later. A new description has therefore been drawn up with attempts to include the complete range of variability of *S. tuberosum* under modern concepts, and this is followed by reference to the main features that distinguish it from other potato species.

The views of the Russian taxonomists on the subdivision of the cultivated tetraploid potato into two distinct species are outlined. The criticisms levelled at these views show that it is impossible to separate the cultivated tetraploids into more than one species and that the weed tetraploids previously described as distinct should also be included within *S. tuberosum*. Experimental data support these views.

An analysis of the difference between the Andean and Chilean South American potatoes makes it possible to recognize two subspecies, namely, (*a*) subspecies *andigena* from the mountains of Venezuela, Colombia, Ecuador, Peru, Bolivia and north Argentina; (*b*) subspecies *tuberosum* from Europe and South Chile. That the European and Chilean potatoes are included under the same subspecific name does not imply that the former were derived from the latter; but that each evolved under similar environmental conditions from original Andean stocks.

As to the origin of the tetraploid potato, it can be considered as an autotetraploid, but may have been formed as an amphidiploid hybrid between two species the genomes of which were not quite identical.

The conclusion is that *S. tuberosum* was derived from an already cultivated diploid species and not directly from a wild one. Indeed, it seems probable that the cultivated potato *S. stenotomum* or a precursor of this species was the original diploid ancestor of our tetraploid potato. There is also evidence that the weed diploid *S. sparsipilum* may also have played some part in the formation of *S. tuberosum*, though cytological opinion is more strongly in favour of *S. stenotomum*.

STRUCTURE OF TOBACCO MOSAIC VIRUS

Radial Density Distribution in the Tobacco Mosaic Virus Particle

MEASUREMENTS of the equatorial scattering of X-rays by orientated gels of tobacco mosaic virus[1] have been used for calculating the mean electron density in the virus as a function of distance from the axis of the rod-shaped particle. Using a Geiger-counter diffractometer with monochromatic copper $K\alpha$ radiation, accurate, high-resolution recordings of the equatorial scattering have been obtained for values of $2\sin\theta/\lambda$ up to 0·06, and for $2\sin\theta/\lambda$ between 0·06 and 0·094 intensities have been estimated from photographs.

Over the angular range examined, the amplitudes of the intensity maxima are real since, for a helix such as tobacco mosaic virus[2], this part of the pattern is determined only by the cylindrically averaged density[3]. Sign relations between some of the maxima can be established from their regular periodicity in certain regions. Where this periodicity corresponds to a dimension about that of the particle diameter, it follows that the amplitude changes sign at the zeros separating the maxima[4]. Radial density distributions were calculated for the sign combinations consistent with these sign relations, and all but two sets were found to be improbable since they would require an unreasonably large diameter for the particle and unlikely density values. Unambiguous determination of the correct set of signs was made from the changes in the equatorial X-ray scattering produced by lead bound to the virus.

When tobacco mosaic virus is treated with lead acetate, lead is specifically bound, and the virus (in concentrated solution) remains soluble with up to about one lead atom added per 17,000 molecular weight of virus. The differences in X-ray scattering from orientated gels of normal and lead-substituted tobacco mosaic virus were used to calculate the radii at which the lead is fixed and to establish the signs of the amplitudes. Equal amounts of lead are found to bind at radii of 25 A. and 84 A.

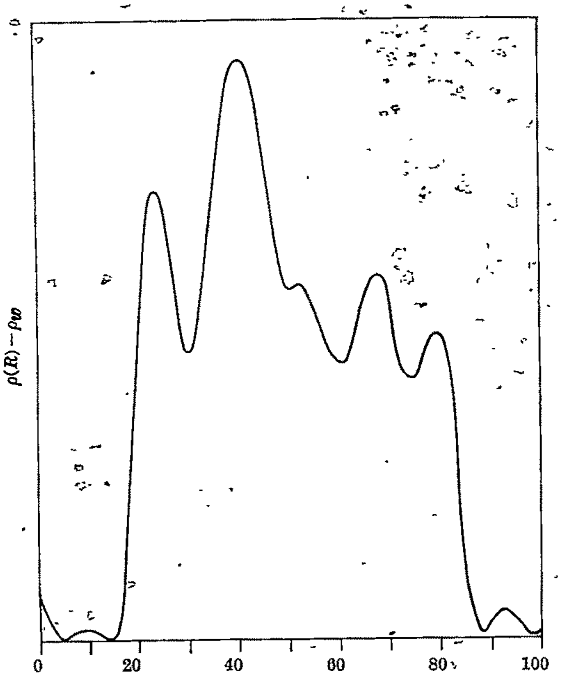

Fig. 1. Radial electron-density distribution in the tobacco mosaic virus particle plotted as a function of distance from the axis of the particle. Ordinate values are proportional to the mean density in excess of that of water

Using the signs so determined, the Fourier–Bessel transform of the equatorial amplitudes has been calculated to give the radial density distribution in the virus particle. This is shown in Fig. 1.

The following features of this transform should be noted: (1) The tobacco mosaic virus particle is hollow. A hole of radius about 19 A. extends along the axis of the particle. (2) The effective radius of the virus in solution is about 84 A., which is appreciably greater than the value 75 A.[1] obtained from the inter-particle distance in dry paracrystals. This difference is consistent with the results of Franklin and Klug[5], who found that there are rather deep indentations in the virus surface which follow the pitch of the helix in such a way that the particles can intermesh in the dry paracrystals. (3) There is a region of high density at a radius of 24 A. and one of higher density at 40 A. The peaks of smaller density at about 67 A. and 79 A. are also significant, but the other minor peaks are diffraction effects from the termination of the Fourier–Bessel integral.

Electron microscope studies[6] have shown that the ribonucleic acid in tobacco mosaic virus is located near the particle axis. From the present work alone it is not possible to decide at what radius the ribonucleic acid is located. This question is resolved by comparison of this density distribution for the normal virus with that for the ribonucleic acid – free virus protein, described by Dr. R. E. Franklin in the following communication.

Details of this work, which was supported in part by a grant from the U.S. National Science Foundation, will be described elsewhere.

Location of the Ribonucleic Acid in the Tobacco Mosaic Virus Particle

IN the rod-shaped particle of tobacco mosaic viru the protein is in the form of sub-units set in helica array about the long axis of the particle[1]. Electro microscope studies[2] have indicated that the viru nucleic acid may form an axial core. In this com munication, however, a brief account is given of an X-ray diffraction investigation which provides strong evidence that the nucleic acid in the intact virus particle does not lie very close to the particle axis. The nucleic acid seen as a core in electron micrographs of partially degraded tobacco mosaic virus is therefore presumably in a collapsed form.

Using monochromatic copper $K\alpha$ radiation and a high-resolution focusing X-ray camera, measurements have been made of the scattered intensities on the equator and layer-lines of X-ray fibre-diagrams of orientated gels of the following substances: (1) tobacco mosaic virus, normal strain, prepared by Dr. H. Fraenkel-Conrat; (2) a mercury-substituted tobacco mosaic virus containing one mercury atom per 20,000 molecular weight of protein, prepared by Dr. H. Fraenkel-Conrat; (3) repolymerized *A*-protein prepared by Prof. G. Schramm[3]. This material is obtained from a normal strain of tobacco mosaic virus by breaking down the virus in weak alkali, removing the nucleic acid by electrophoresis, and repolymerizing the protein by lowering the *p*H.

A few non-monochromatic measurements were also made on a mercury-substituted repolymerized *A*-protein prepared by Dr. H. Fraenkel-Conrat.

The above materials, although prepared in two different laboratories, were all obtained from 'normal' virus strains. All normal strains of tobacco mosaic virus which we have so far examined give X-ray diagrams which are almost indistinguishable from one another. Moreover, our equatorial intensities, obtained photographically, are in excellent agreement with Caspar's data[4] obtained with a Geiger counter and a different virus preparation. Quantitative comparisons of diffraction data obtained from the materials listed above are therefore justified. The main purpose of this communication is to report such a comparison of accurate measurements on the normal tobacco mosaic virus and the repolymerized *A*-protein preparations (1 and 3 above).

It has previously been shown[5] that the X-ray fibre-diagram of repolymerized *A*-protein resembles that of tobacco mosaic virus so closely that there can be no doubt that the structural arrangement of the protein characteristic of the virus is preserved in the repolymerized protein. There are, however, important points of difference in the two diagrams. These are most marked on the equator, but are significant also on all the layer lines which can be accurately measured. It is from a study of these differences that the location of the nucleic acid in the tobacco mosaic virus particle can be determined.

Before discussing the differences between the tobacco mosaic virus and repolymerized *A*-protein diagrams, however, it is necessary to mention some results obtained from a comparison of the normal and the mercury-substituted virus, that is (1) and (2) above (Franklin, R. E., and Holmes, K. C., unpublished results). This has both served to confirm Caspar's allocation of signs[4] to the equatorial intensity maxima of the normal virus, and led to a new determination (Franklin, R. E., unpublished results) of the hitherto somewhat uncertain parameters of its helical structure[1,6]. This makes it possible to make the comparison between tobacco mosaic virus and repolymerized *A*-protein by two independent methods.

In the first method, the intensities recorded on the layer-lines for the two materials were compared. Using the newly determined parameters of the helical structure of the virus it can be shown that, on each of the first eight layer-lines, the principal difference between the X-ray diagrams of tobacco mosaic virus and repolymerized *A*-protein must be attributed to a structural difference at a radial distance of about 40 A. from the particle axis. This strongly suggests that the nucleic acid in tobacco mosaic virus is situated in this position.

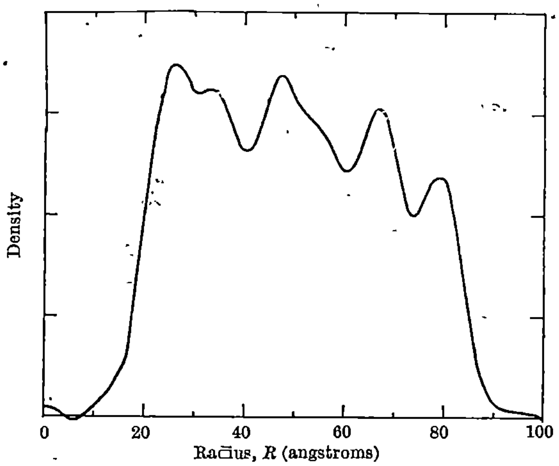

Fig. 1. Radial density distribution in repolymerized, nucleic acid-free tobacco mosaic virus protein. Ordinates are proportional to the excess electron density of the protein over that of water. Note that the density maximum observed at 40 A. for the complete virus (ref. 4) is here replaced by a density minimum

The second method is independent of the helical structure of the virus. The radial density distribution in repolymerized *A*-protein has been calculated by means of the Fourier–Bessel transform of the equatorial amplitudes. Amplitudes for values of $2\sin\theta/\lambda$ up to 0·1 were used for this purpose. It was found possible to determine the signs of the amplitudes unambiguously in this range by comparing the intensity data with those for tobacco mosaic virus on one hand, and mercury-substituted repolymerized *A*-protein on the other. To eliminate or reduce spurious peaks in the transform, an 'artificial' temperature factor' of $\exp\{-(11{\cdot}8 \times 2\sin\theta/\lambda)^2\}$ was imposed on the amplitude data. The resulting radial distribution function is shown in Fig. 1.

This distribution bears sufficient resemblance to the density distribution of tobacco mosaic virus calculated by Caspar[4] to show once again (cf. ref. 5) that the structural arrangement of the protein in the two materials is very similar indeed. (Some minor points of difference between the two curves may be attributed to the different cut-off position used and to the use of an 'artificial temperature factor' for the repolymerized *A*-protein. For example, the small peak at 53 A. in Caspar's curve is a spurious maximum resulting from the sharp cut-off at $2\sin\theta/\lambda = 0{\cdot}094$.) But there is one striking difference between the two curves. Whereas tobacco mosaic virus has its strongest density *maximum* at a radial distance of 40 A., repolymerized *A*-protein has a pronounced *minimum* at just this position. The radial density distribution in the protein thus provides strong confirmation of the conclusion, reached independently from a study of the layer lines, that the principal structural difference between tobacco mosaic virus and repolymerized *A*-protein occurs at a radius of 40 A. The strong density maximum at 40 A. in tobacco mosaic virus must therefore be due to the presence of nucleic acid at this radius.

In X-ray scattering by nucleic acids, the phosphate group of the nucleotides acts effectively as a 'heavy atom'. X-ray studies of deoxyribonucleic acid have shown[7] that scattering by this compact group can have an effect which predominates over that due to the rest of the nucleotide. It is thus the phosphate back-bone chain of the ribonucleic acid molecule which must lie on a radius of about 40 A. in the tobacco mosaic virus particle.

It will be noted that the first density maximum, at a radius of 25 A., is present in both tobacco mosaic virus and repolymerized *A*-protein, and represents an approximately equal weight of material in the two substances. We must therefore conclude that, whereas the 40-A. density peak in tobacco mosaic virus is due to nucleic acid, the 25-A. peak is due to protein. Thus the nucleic acid in tobacco mosaic virus is deeply embedded in the virus protein. Its molecular structure and chain direction must therefore be closely related to the structural arrangement of the protein. Further study of the X-ray data is in progress with the view of determining how many nucleic acid chains the tobacco mosaic virus partic contains, and in exactly what direction they run.

The work summarized above will be described : detail elsewhere. I am most grateful to Dr. I Fraenkel-Conrat and to Prof. G. Schramm for su plying me with the tobacco mosaic virus and vir derivatives used in this investigation. The work w supported by the Agricultural Research Council.

PROPAGATION OF AUDIO-FREQUENCY RADIO WAVES TO GREAT DISTANCES

By DR. F. W. CHAPMAN and R. C. V. MACARIO
Wheatstone Laboratory, King's College, London

THE propagation of low-frequency radio-waves was studied many years ago using long-wave commercial transmitters. The well-known Austin–Cohen law was widely used for estimating field-strengths, and because of the theoretical justification of its general form this law was used as a basis for the computation of attenuation coefficients at very low frequencies. According to the law, the attenuation of signals decreases as the frequencies decrease; in fact, at a frequency of 3 kc./s. or less, the attenuation would appear to be very small indeed. The absence of observations at frequencies less than about 12 kc./s., however, meant that the mode of propagation of radio waves at lower frequencies was for many years the subject of speculation.

Now in the course of our observations on the electromagnetic waves radiated by lightning discharges, we have found evidence of a high attenuation of waves in the frequency-range of 2–3 kc./s., in complete contradiction to that predicted by the Austin–Cohen law.

In the original observations on these naturally-occurring disturbances known as atmospherics[1], it was found that they acquired characteristic patterns during their passage between the ground and the ionosphere. An inspection of their wave-forms up to very considerable distances from the source clearly showed that the main concentration of energy lay in the audio-frequency band below 10 kc./s. and that the higher-frequency components moved forward relative to the lower-frequency or 'slow tail' components as the distance of propagation increased. Furthermore, it was observed that a band of frequencies in the neighbourhood of 2 kc./s. was either entirely missing or at least very heavily attenuated. This band of missing frequencies lay between the predominant frequency of the characteristic 'oscillatory head' and the 'slow tail' of the atmospheric and, as was stated earlier[1], unless there is some factor operative corresponding to anomalous dispersion for the missing frequencies, the higher-frequency group and the slower disturbance do n originate in exactly the same portion of the discharg

It is pertinent to remark here that Eckersley his early studies of radio-transmission[2] question the continued validity of the Austin–Cohen law wi decreasing frequency of the wave. In fact, he su gested a theoretical reason for supposing that tl attenuation ceases to decrease at frequencies low than about 12 kc./s.

In order to elucidate this problem, we hav during the past few years, supplemented atmosphe wave-form observations by simultaneously recordi the relative amplitude of the frequency componen in the spectrum of the wave-form. In their fir experiments, Chapman and Edwards[3] recorded t wave-forms and corresponding response of a numb of narrow-band receivers tuned to frequencies in t range 1–25 kc./s. The amplitude of the vario frequency components was calculated from the responses and the observed spectrum of atmospheri due to lightning strokes between the cloud a ground compared with that to be expected fro this type of discharge. Later, Chapman and Matthew used an improved apparatus covering the frequen range 40 c./s. to 16 kc./s. split by twenty-seven ban pass filters arranged logarithmically at three chann per octave. Here the amplitude-frequency spectru was presented directly on the screen of a cathode-r tube and photographed along with the correspondi wave-form. They discussed the relation between t well-known wave-form characteristics and the si nificant changes in the spectrum as the distance propagation increases.

In our more recent experiments we have appli magnetic tape sound-recording techniques[5] to obta permanent records of the complete history in tir of all the disturbances appearing at the aerial vertical rod). A second channel on the tape, link by telephone line to the Meteorological Offi C.R.D.F. network for locating thunderstorm centr provides information on the source of individu

:mospheric disturbances. The ndom distribution of the differ- it types of atmospheric and their nplitude in relation to the con- nuous background noise-level at ie site can thus be readily assessed. he spectrometer has also been odified to record single wave- rms and their amplitude-fre- iency-spectra at a maximum rate ' one record per second, and an ectronic switching device ensures iat spurious signals do not add the spectrum recorded.

The results to be described are ised on one particular type of :mospheric, namely, that resulting om cloud-to-ground discharges id at known distances up to about 000 km. Observations have been ade under both day and night nditions of propagation and at fferent seasons of the year. The tenuation coefficient of signals in ie frequency range 40 c./s. to ; kc./s. has been computed from ie experimental results for both nd and sea paths and different nospheric conditions. In all cases ie presence of a marked absorption ind has been found at a frequency ' 1 or 2 kc./s. Finally, the results ɔtained are compared with the ırlier long-wave transmission results and the more :cent theories of propagation.

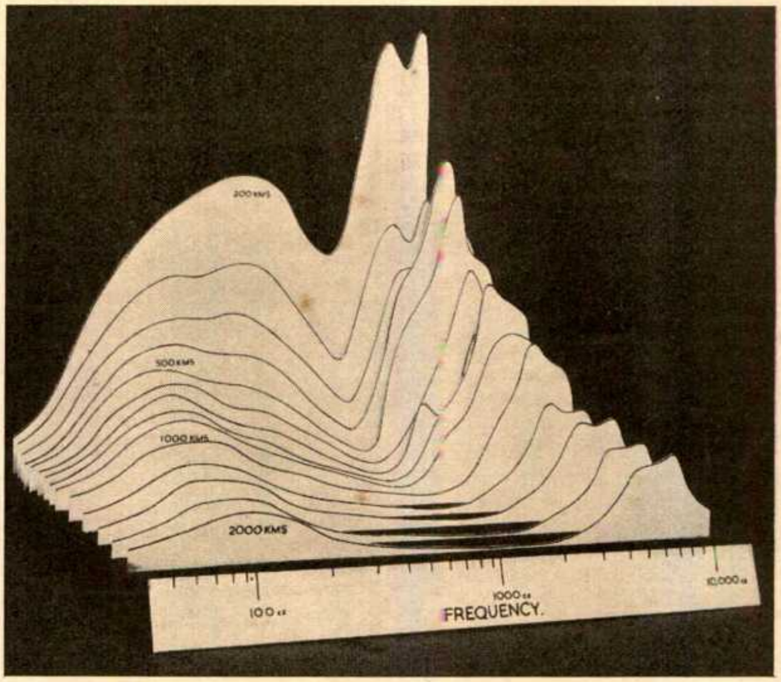

Fig. 1. Model showing the relative amplitude of the frequency components of atmospherics resulting from an average cloud-to-ground lightning stroke observed by day at different distances from the source. The vertical scale shows relative amplitudes in micro-volt, sec./metre (1 cm. in the model corresponds to 10 micro-volt, sec./metre)

In Fig. 1 is shown a photograph of a model illus- ·ating the way the spectrum of the disturbance ıdiated by an average cloud-to-ground lightning roke varies with the distance of propagation. This articular model was constructed from a large ımber of observations made on land sources at ɔon during winter months. It clearly shows that ith increasing distance the various frequency com- ɔnents, besides falling off in amplitude due to a vo-dimensional divergence of energy, also suffer ·lective attenuation due to ionospheric influences ; had previously been reported by Appleton and hapman[1]. The preponderance of energy in the ghest and lowest frequency-ranges represents the ımiliar 'oscillatory head' and 'slow tail' parts of the ave-form, respectively.

It is not our purpose to discuss here the various 'pes of disturbance and their characteristic spectra ; ut it should be mentioned that frequently the 'slow- iil' components are either absent or at least very nall. This is undoubtedly an effect of the source ɜpendent on the mode of destruction of the thunder- oud charge by the lightning stroke, that is, whether : not the current in the discharge channel rapidly ɜcreases after the 'return stroke' has reached the oud[6]. However, in all cases of both high- and very ·w-frequency radiation at the source, there is an ɔsorption band in the spectrum of the distant :mospheric which is clearly the result of propa- ıtion. This phenomenon, together with the law of ropagation at these very low frequencies, are the ıbject of our present discussion.

In dealing with our experimental results, we are ıced with two problems. What is the strength of ıe signal radiated at the source on any particular ·equency channel, and how does propagation affect the amplitude of the signal observed on this channel at a distance ? It will be seen that we cannot interpret our observations without some knowledge of one or the other.

The diverse nature of lightning discharges makes it difficult to derive any useful data on the spectrum of the radiation field at the source, although some information already exists for a simple type of discharge[3,7]. However, as regards the effect of propagation, it is possible to be more definite.

It is well known that electric waves of very low frequency are guided around the earth by the ionosphere and, as already indicated, many attempts have been made, both empirical and theoretical, to derive expressions for the signal-strength $E(f,r)$, where f is the frequency and r the distance of propagation. A survey of the extensive literature on the subject indicates that the main contribution to the signal-strength may be represented by an expression of the form

$$E(f,r) = A(f)r^{-1/2} \exp [- \alpha(f)r]$$

(200 km. $< r <$ 3,000 km.), where $A(f)$, the amplitude coefficient, depends on the spectrum at the source and $\alpha(f)$ is the attenuation coefficient.

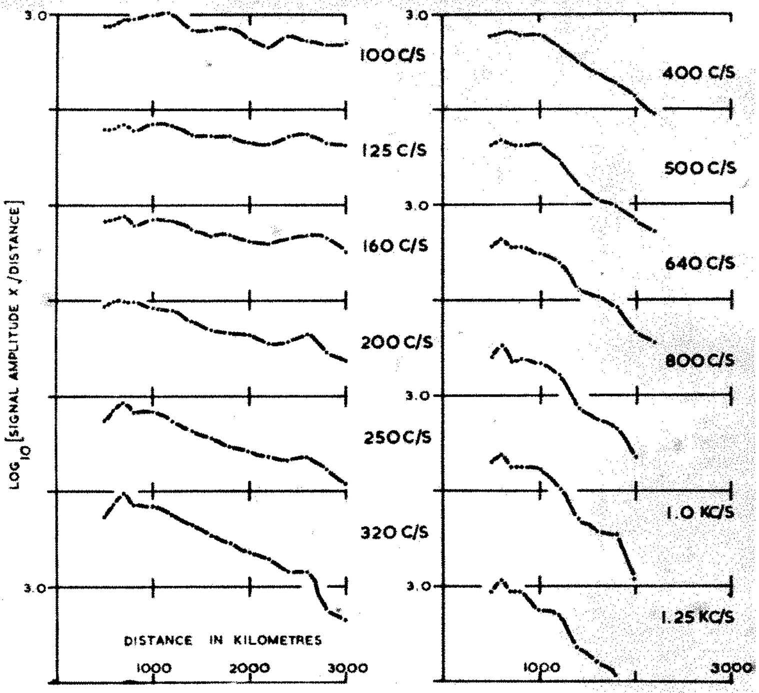
This is essentially the formula used by Round, Eckersley, Tremellen and Lunnon[8] for the interpretation of their observations on the propagation of signals from long-wave transmitters (frequencies down to 12·5 kc./s.), and as will be seen later, there are good grounds for assuming that the formula may be applied at much lower frequencies.

According to the above expression, the value of the quantity $\log [E(f,r)r^{1/2}]$ at any particular frequency varies linearly with the distance r, so that the value of the attenuation coefficient $\alpha(f)$ at that frequency can be determined directly from the slope of the line obtained by plotting the results in this way. This was the method used by Round and Eckersley[8] and later by Budden[9] in his discussion of the measurements made by Weekes on the field-strength of the 16 kc./s. Rugby transmitter *GBR*.

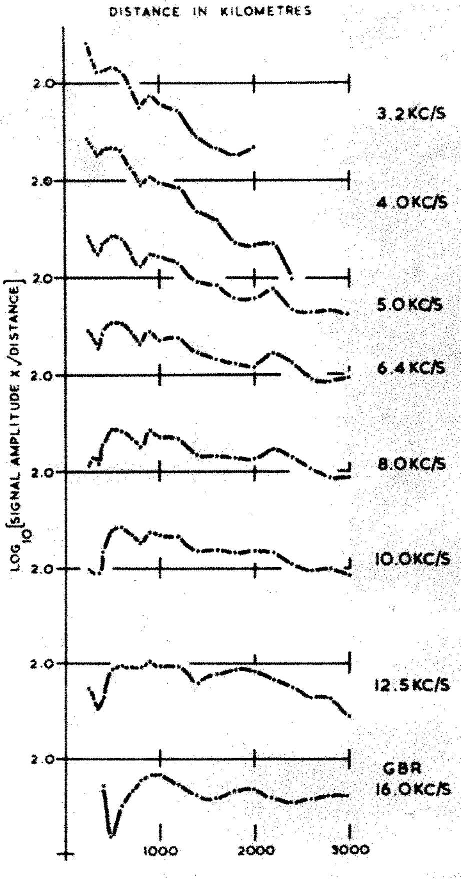
In Fig. 2 (*a*) and (*b*) we have plotted our results for a number of frequency components derived from the spectrum of atmospherics and ranging from a frequency of 100 c./s. to 12·5 kc./s. For comparison, the corresponding curve given by Budden[9] for *GBR* is included. It will be seen that each curve shows a characteristic variation with distance more pronounced at shorter distances. Budden considered that the variations in field-strength for *GBR* could be explained in terms of the interaction of two predominant modes of propagation in the wave-guide bounded by the ground and the ionosphere. Ya L. Al'Pert[10] also calculated this kind of variation of signal-strength with distance for *GBR*. The striking similarity in the form of the curves derived at lower frequencies using atmospherics and that measured by Weekes and Budden for *GBR* transmissions is to be noted. Also, the results for frequencies less than 1·5 kc./s. do not show this effect so markedly.

Evidently, by smoothing out the effect of the secondary modes of propagation, the mean slope of the straight line obtained for each channel gives a value for the attenuation coefficient of the principal mode or main signal contribution on that channel. The values of $\alpha(f)$, expressed in decibels per 1,000 km. path, are plotted against frequency in Fig. 3 for both day and night conditions of propagation, the experimental values for which are marked by circles and crosses, respectively. The values of the attenuation coefficient over the frequency-range 20–30 kc./s. as measured by Eckersley[8], using signals from long-wave transmitters, are shown for comparison. These follow fairly closely the Austin–Cohen law of attenuation, which predicts a progressive decrease in the value of $\alpha(f)$ as the frequency is lowered but fails to account for the remarkable increase in attenuation at about 10 kc./s. to a maximum value at a frequency of two or three kilocycles per second. The propagation path, in fact, exhibits selective absorption, which, together with the low attenuation at the extreme ends of the audio-frequency range, accounts for the observed long-distance propagation characteristics of atmospherics[1]. As is to be expected, the attenuation at all frequencies is greater by day than by night, but the difference between the day and night values is greatest in the region of maximum absorption.

We recall here the experiments of Gardner[11], who recorded the integrated noise-level of atmospherics using four receivers tuned to different frequencies between 3·5 and 50 kc./s. Gardner found that the ratio of the day to night noise-level was less at 3 kc./s. than at 10 kc/.s., from which he inferred that the onset of daylight conditions gave a marked increase of attenuation for frequencies less than 10 kc./s. These conclusions were confirmed by



(*a*)



(*b*)

Fig. 2 (*a*) and (*b*). Variation with distance of log $E(f,r)r^{1/2}$ at different frequencies. (The interval between horizontal lines represents one unit on the logarithmic scale)

Bowe[12]. From our observations, it is clear that the greatest increase in attenuation occurs at a frequency of about 2 kc./s., it being then about 10 db. greater than at either 10 kc./s. or at 200 c./s.

It is of interest now to compare our results with those predicted by Budden, assuming propagation in a 'waveguide' bounded by a perfectly conducting Earth and an imperfectly conducting sharply bounded ionosphere. The full-line curves *A* and *B* in Fig. 3 are those derived by Budden[13] for the different ionospheric parameters quoted. The attenuation coefficient so calculated as a function of frequency relates to the zero-order mode of propagation, as do our experimentally determined values. The parameter p_r depends on the ratio N/ν where for the upper boundary there are N electrons per c.c., and these are assumed to make an average of ν collisions per second. The orders of magnitude of N and ν for the region in question are 10^2 cm.$^{-3}$ and 10^7 sec.$^{-1}$, respectively; but, as Budden has pointed out, although a small change in p_r does not result in any marked change in the form of his curves, changes in the value of h (the height of the upper boundary) have an appreciable effect. It is also known that the height of reflexion of very long waves is greater at night than by day, and the general agreement between the theoretical and experimental values of $\alpha(f)$ both substantiates the waveguide theory and the experimental method followed in this work. Moreover, the appropriate value of h for these very low-frequency waves can be inferred from the measurement of their attenuation.

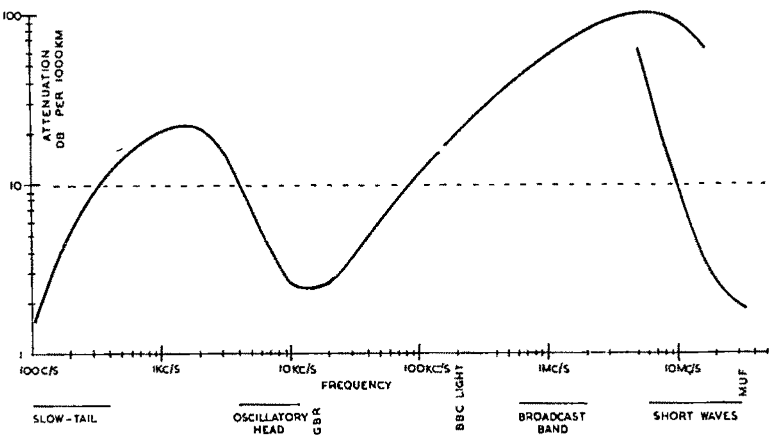


Fig. 4. Variation of attenuation with frequency. The curve for the frequency range 30 kc./s. to 30 Mc./s. is taken from Eckersley (ref. 2, Fig. 31)

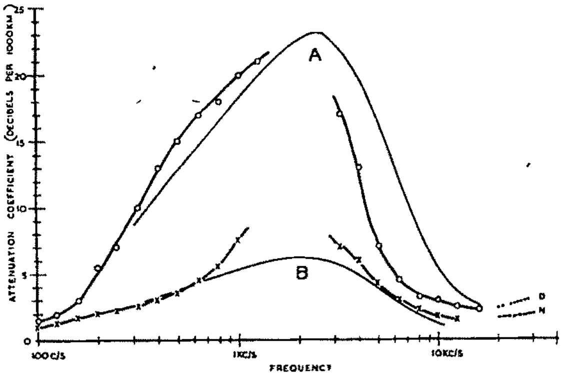

Fig. 3. Variation of attenuation coefficient with frequency for propagation over the ground

—○—○—, Day-time values; —×—×—, night-time values compared with the theoretical curves for different ionospheric parameters; *A*, ionospheric height, $h = 50$ km., $p_r = 6 \times 10^4$ sec.$^{-1}$, and *B*, for $h = 80$ km and $p_r = 2 \times 10^5$ sec.$^{-1}$. Eckersley's values, ...; *D*, day, and *N*, night

The attenuation curves shown in Fig. 3 were derived from atmospherics originating in European storm centres and relate to propagation over the ground. A difference, however, has been found for Atlantic sources giving an appreciable sea-path, the most striking difference being the improved transmission of signals at the higher frequencies, particularly in the region of 5 kc./s. This is undoubtedly an important factor in determining the characteristic type of atmospheric observed from Atlantic sources. Further, the diurnal and seasonal differences in propagation, which will be dealt with elsewhere, clearly follow changes in the ionosphere. For all ionospheric conditions the same type of attenuation curve is obtained. There is a marked selective absorption band, and this is associated with a discontinuity in the group velocity of the waves. Calculations have shown that the group velocity of the atmospheric 'slow tail' component is less than that for the higher-frequency 'oscillatory head', and that in the neighbourhood of the absorption band the group velocity decreases rapidly.

Finally, in Fig. 4, we link the results of the work now described with the attenuation curve for long-distance day transmission of radio signals of frequency up to about 30 Mc./s. as given by Eckersley[2]. This curve gives a fair idea which waves are the least attenuated and can travel to the greatest distances. It is a remarkable property of the ionosphere that extremely low-frequency waves less than two or three hundred cycles per second only suffer the same small attenuation as that assigned to the short waves so extensively used in world-wide communication.

The work described here was carried out with the co-operation of the Meteorological Office Sferics Organization for the location of the sources of atmospherics, and without which the investigation would not have been possible. We gratefully acknowledge our indebtedness to the Director of the Meteorological Office and his staff, also to the Department of Scientific and Industrial Research for a grant to cover the cost of equipment.

Sensitivity of the Mouse Testis to the Mutagenic Action of X-rays

Dr. C. Auerbach is a recognized authority on the induction of mutations, and her publications are likely to carry considerable weight. There is a danger, therefore, that the recent letter in *Nature*[1] (claiming to have detected greater mutational sensitivity in spermatids than in sperm) may have greater weight attached to it than the results would warrant. The authors admit the paucity of their data; but a number of other criticisms can be made.

The usual method of classifying sperm samples in the mouse is by time from irradiation rather than order of the litters conceived by it. This is the classification used by Russel and Hertwig, with whose results Auerbach and Slizynski compare their own. It would be of interest, therefore, to learn whether the alternative classification of these data gives the same picture of variation in sensitivity.

The class sizes are rather small for the χ^2 test to be applied to the variation due to the order of litters, but this yields a χ^2 of 5·8056 for 7 degrees of freedom, which is non-significant ($P = > 0{\cdot}5$). Drs. Auerbach and Slizynski have crammed a large part of this non-significant χ^2 into 1 degree of freedom which they have selected as giving the maximum difference between two groups.

Finally, if more extensive observations did confirm their empirical conclusions, there would remain the question of interpretation. Auerbach and Slizynski expected to find spermatids more sensitive than mâture sperm. Thus, when they believed they had found an ultra-high mutation-rate in the fifth and sixth litters, they assumed that these represented the irradiation of spermatids and that their three-week mating period represented at least all post-meiotic stages. But this is most unlikely. My own work (unpublished) has shown that following a dosage of 200 r., male mice remain fully fertile for five weeks, throughout which period dominant lethals are detectable. After a sterile period of about one week, full fertility is restored without dominant lethals. Thus the interval from meiosis to the utilization of the sperm initiated at that meiosis is about six weeks, and Auerbach's and Slizynski's samples, as those of other workers using doses of 400–600 r. and higher, were probably confined to irradiated sperm or at most late spermatids. Presumably spermatids irradiated with the higher doses fail to produce viable sperm.

[1] Auerbach, C., and Slizynski, B. M., *Nature*, 177, 376 (1956).

We are grateful for the opportunity of replying to Dr. Bateman's criticism.

(1) The main and most pertinent of his objections is levelled against the small scale of our experiment. We fully agree with him on this point. We thought we had made this clear when we described our work as a "pilot experiment", for which "confirmation on a larger scale is desirable". It is true that, from purely statistical point of view, it would not b permissible to apply a test of significance to a difference between two parts of a series which as a whole shows no significant deviation from homogeneity Nevertheless, we felt justified in applying such a tes to the two non-overlapping groups of points in ou curve; for our working hypothesis had been that translocation frequency would show just such discontinuity about midway through the presterile period, and that the change would be from a lowe to a higher frequency. We based this expectatio on the much more extensive work by Hertwig[1] an Russel[2], which clearly shows that, after irradiatio with either X-rays or neutrons, dominant lethality is higher in the late than in the early stages of th presterile period. Since with the doses used by thes workers 30 per cent or more of dominant lethal presumably are due to inviable translocations, i would indeed be unexpected to find that translocations do not follow the same trend. The fact tha our results agreed with expectation was taken to reinforce the findings on dominant lethals and together with these, furnish 'presumptive evidence for a varying degree of sensitivity in post-meioti stages of spermatogenesis. Again we thought w had made this clear in our communication.

The remainder of Dr. Bateman's objections ar based on his own observations. Since these have no been published and are only vaguely hinted at in hi communication, we could not, and cannot now, take account of them. Whatever the nature of these observations, they appear to contradict results by Snell, Hertwig, Russel and others[3]. Admitting the possibility that Dr. Bateman's newer data may make a re-assessment of the older work necessary, we can at the moment base our conclusions only on these older, generally accepted results.

(2) We considered that the number of copulations would be a better measure of sperm utilization than time after irradiation. For *Drosophila*, Dr. Bateman himself has shown[4] that sexual activity, more than time, determines rate of sperm utilization. For the mouse, Hertwig has shown the same[1]. In fact, however, there is scarcely any difference between the grouping of our data by time or by litter number All litters in our first group were conceived between the first and eleventh day after irradiation, and the remainder between the eleventh day and the onse of sterility in the third or fourth week. The only overlap was a fifth litter of one male, which had been conceived on the eleventh day.

(3) Russel[3], basing himself on all available evidence up to 1954, states that "there is now almost unanimous agreement that spermatocytes, spermatids and sperm are resistant to radiation and that spermatogonia are quite sensitive". In a footnote he mentions that also primary spermatocytes "show appreciable sensitivity", and this agrees with Hertwig's opinion. We therefore felt justified in the assumption that, by testing all litters from the presterile period, we were sampling all post-meiotic and, possibly, late meiotic stages, and that therefore the increase in translocation frequency after the fourth litter was due to admixture of spermatozoa which at the time of treatment had not yet reached maturity. Whether these immature stages should be called "spermatids", or "late spermatids" (as Dr. Bateman does), seems a secondary question, which cannot be decided on the present evidence. The relevant point is the existence of a stage in spermatogenesis, prior to complete matura-

tion of the sperm and probably after meiosis, which is more sensitive than mature spermatozoa. The only alternative to this interpretation is that the amount of chromosome damage is increased in irradiated mature spermatozoa which are stored in the testis. This possibility has been considered by Hertwig, who tested and rejected it on the evidence of experiments in which irradiated males were kept for seventeen days before their first matings.

(4) Dr. Bateman seems to give much weight to the observation that in his own experiments with 200 r. the presterile period and one week of sterility together extended over six weeks. However, the length of the presterile period varies considerably between experiments (see Table 12–1 in ref. 3) and is certainly, as established by Hertwig, dependent on the amount of sexual activity of the males. The length of the sterile period varies even more between experiments and is determined mainly by the dose and the correlated more or less severe damage to spermatogonia. The sum of these periods is therefore not suitable for determining the time interval between meiosis and the availability of mature sperm. This interval is almost certainly much shorter than six weeks, as shown by older histological observations (see ref. 3) as well as by newer work with labelled phosphorus[5].

A Convulsant Alkaloid of *Dioscorea dumetorum*

An alkaloid, dioscorine, has been isolated from various species of yam of the family Dioscoreaceae. Pinder[1] has summarized the history of this, confirmed its molecular formula as $C_{13}H_{19}O_2N$ and has documented certain of its chemical and physical properties[2]. A similar alkaloid has been extracted from a further species common in the wild state in Nigeria and identified by its botanical characteristics and typically small starch grains as *Dioscorea dumetorum* (Yoruba name, èsúru[3]).

The latter alkaloid has not been obtained crystalline, but has been extracted and purified by various procedures; together with its crystalline salts, its analysis supports the formula $C_{13}H_{21}O_2N$. Its infra-red and ultra-violet spectra differ from those reported for dioscorine. Thus the *D. dumetorum* alkaloid shows a single absorption maximum at 2080 A. on a calibrated 'Unicam' spectrophotometer as compared with a maximum at 2170 A. reported for dioscorine. The chemistry of the former is being further investigated.

When injected into mice, the alkaloid of *D. dumetorum* acts as a convulsant poison. The convulsions are usually clonic at first, later tonic and may be followed either by death or recovery. When injected by the intra-peritoneal route, using a freshly prepared 1 per cent aqueous solution, the *LD*50 is approximately 65 mgm./kgm. Concentrations of 10^{-5} reduce the response to acetylcholine on the isolated guinea pig ileum and isolated rabbit duodenum preparations. At a dose-level of 20 mgm./kgm. the responses of the cat's blood pressure to acetylcholine and to adrenaline are altered. The depressor effect of the former is reduced, and the pressor effect of the latter is enhanced. No local anæsthetic effect could be demonstrated. Dioscorine[2] apparently lacks atropine-like properties in the concentrations mentioned above, nor does it potentiate the action of adrenaline on the cat's blood pressure.

We are indebted to Mr. B. Reiff for technical assistance. Grants from the Nigerian Government Fund for the Investigation of West African Drugs and Medicines are gratefully acknowledged.

Aminomalonic Acid Decarboxylase: a New Enzyme

Aminomalonic acid was first described by Baeyer[1] in 1864, who found that heat treatment converted the amino-acid smoothly into glycine. Knoop[2] suggested the intermediary formation of aminomalonic acid in the biological formation of glycine from serine. But Haas[3] could not find evidence that it is a precursor of glycine in the rabbit, either in experiments on the whole organism, or in the isolated liver, or with liver homogenate. Shemin[4] has claimed to have excluded aminomalonic acid as an intermediate in the metabolic change of serine to glycine from results obtained by isotopic studies. However, this view was criticized by Ogston[5].

In the present communication, we report the presence in animal tissues of an enzyme which catalyses the decarboxylation of aminomalonic acid to glycine. This enzymatic activity was first observed in the homogenate of silk-gland tissue and afterwards in rat-liver homogenate.

The enzyme solutions used in the present work were prepared by homogenizing the posterior silk-glands of silkworms as the fifth instar with 3 vol. of 0·15 *M* potassium chloride and centrifuging off the undissolved material. The test system contained 0·5 ml. of aminomalonic acid solution (88 μmoles per ml., ammonium salt), 1·0 ml. of phosphate or acetate buffer and 1·0 ml. of the enzyme solution.

The rates of the reaction were followed in two ways. In one procedure the determination of carbon dioxide production was carried out with the conventional Warburg manometric apparatus. The amount of glycine formed was also determined. Aliquot samples were taken from the reaction mixtures and deproteinized by the addition of one-third volume of 95 per cent alcohol and boiling for 1 min. in the water-bath. The filtrates were assayed for glycine by a quantitative paper chromatographic technique. The glycine formed was also identified as its 2,4-dinitrophenyl derivative.

The activity of this enzyme solution, expressed as µl. carbon dioxide formed per hr. per 250 mgm. fresh tissue, was about 80. The rate of the reaction was found to be proportional to the time of the reaction over a period of 90 min. under the conditions employed, showing that the kinetics of this reaction is zero order for a limited time. The Michaelis constant was determined as $6 \cdot 5 \times 10^{-2} M$.

The *p*H optimum for the decarboxylation of aminomalonic acid was found to be at 5·9–6·1. The crude enzyme solution did not decarboxylate malonic acid, aspartic acid or glutamic acid.

When the crude enzyme solution was held at 70° for 10 min. or at 100° for 5 min., enzyme activity was entirely destroyed. Several inhibitors were tested, and it was found that the enzyme activity was inhibited completely by hydroxylamine at a concentration of $10^{-3} M$ and also by potassium cyanide at a concentration of $10^{-2} M$.

The activation energy of this enzyme – substrate system was determined over the temperature-range 27°–42°, and found to be about 14,600 calories. This value is considerably lower than that for non-enzymatic decarboxylation in the system $0 \cdot 3 N$ sulphuric acid – aminomalonic acid.

The activity of this preparation was not affected by dialysis against distilled water for three days at 0°–4°. The enzyme was partially purified by fractionation with ammonium sulphate and absorption on and elution from aluminium hydroxide $C\gamma$ and the product was about thirteen times as active as the starting material.

Our results indicate that the decarboxylation of aminomalonic acid takes place by the action of a new enzyme which we propose to call 'aminomalonic acid decarboxylase'.

This work is continuing and will be reported in full elsewhere.

New Amino-Acid – Glycosides isolated from Tryptic Hydrolysates of Milk Products

THE protein – sugar complex formed by interaction between the free amino-group of protein and reducing sugar recently became of interest to food chemists as the first intermediate in the amino-carbonyl (or Maillard) reaction of those systems. The formation of such a protein – sugar complex in milk products, for example, heated milk and dried skim milk, has been confirmed by Henry *et al.*[1] and Patton *et al.*[2] respectively. On the other hand, it has been known that carbohydrate is contained in casein and bound with the amino-acid residue of it in the form of glycoside[3,4]. In consequence, it seems reasonable to assume that carbohydrate can exist in these protein materials either as preformed or as secondarily formed glycoside.

Table 1

	Amino-acid – glycosides	
	I	II
Hydrolysed products by 6*N*-hydrochloric acid	Glucose Galactose	Galactose
Colour reaction with developer: Benzidine	Positive	Positive
Colour reaction with developer: Resorcine	Negative	Positive
Colour reaction with developer: Ninhydrin	Positive	Positive
Hydrolysed products by β-glucosidase	Galactose	Galactose
Alkaline methylamine reaction (for 1 ~ 4-bond) (ref. 7)	Positive	Positive
Cystein-carbazol reaction (for ketose) (ref. 8)	Negative	Positive

While the chemical behaviour of the preformed protein – sugar complex, that is to say, mucoprotein and mucopolysaccharide, and the formation of secondary complexes are now well known, the chemical properties of the complex have not so far been investigated in any detail. The present experiments refer to the isolation and identification of amino-acid – glycosides which are the fundamental constituents of the secondarily formed protein – sugar complex in milk products.

The amino-acid – glycosides were isolated from the tryptic hydrolysates of evaporated milk and dried skim milk by the procedure of Inoue *et al.*[3], and Masamune *et al.*[4], except that the large-scale multiple paper chromatogram was used for purification of the crude material. The developed paper was sprayed with aniline hydrogenphthalate and ninhydrin reagents. The chromatograms gave three spots (I ~ III) corresponding to amino-acid – glycosides. The R_g values calculated from four chromatograms of I, II and III showed, respectively, 0·21, 0·55 and 0·87.

To confirm the presence of these compounds in milk protein, casein[5] and whey protein isolated by the method of Kondo *et al.*[6] were used to prepare amino-acid – glycosides according to the procedure described. Paper chromatograms from both these substances gave essentially the same spot, corresponding to III. The most reasonable conclusion to be drawn from these results is that I and II are secondarily formed glycosides, and that III is originally present in raw milk.

On the basis of the results shown in Table 1, it is suggested that the carbohydrate constituents of glycosides I and II were β-galactosyl-α-glucoside (lactose) and β-galactosyl-1-deoxy-α-fructoside (lactulose), respectively. The liberation of these disaccharides from the glycosides by treatment with 'Amberlite *IRA*-410' in the H+ form confirmed the presence of these glycosidic linkages in them. The presence of the disaccharide of I and II in the eluate was proved by comparison with corresponding standard compounds.

The aglycones of these materials were liberated without decomposition of the peptide bonds by treatment with *N* hydrochloric acid. As paper chromatograms sprayed with ninhydrin gave a spot of the same R_F for various solvents, it seemed that the aglycones of I and II are identical and are derived from the same secondarily formed protein – sugar complex in the milk products. The constituent amino-acids of the aglycones were histidine, alanine, lysine, leucine, with traces of glutamic acid, aspartic acid, serine and valine. Accordingly, it may be concluded that I is converted to II in accordance with the Amadori rearrangement, and that this rearrangement is carried out on the glucose residue bound to the amino-radical of the aglycone. It may also be seen that the terminal amino-acid of aglycone bound to those carbohydrates is lysine derived from casein as shown by some workers[9,10].

I wish to thank Profs. R. Sasaki and T. Nakanishi for advice and criticism. These investigations are being continued, and a full account will be published elsewhere.

Oxygen Consumption and Active Transport of Sodium in the Isolated, Short-circuited Frog Skin

FOR the isolated, short-circuited frog skin with Ringer solution on both sides, it has been found that the active transport of sodium is equal to the current required to reduce the potential difference across the skin to zero[1,2]. It is also a well-known fact that the active transport of sodium depends on the oxygen supply to the skin. Francis and Pumphrey[3] found that oxygen-free Ringer solution caused an irreversible disappearance of the potential difference across the kin in the course of 20–40 min.

It was the purpose of the present study to investigate the relation between sodium transport and the oxygen consumption in the frog skin (*Rana temporaria*). In principle, the apparatus employed was the ame as that used by Ussing and Zerahn[1]; but it was made exclusively of glass, since Andersen and Lehmann (personal communication) have found that 'Perpex' is not suited for such investigations. The solution was circulated by the action of a magnetic field on an iron core sealed into glass. The apparatus was assembled with the frog skin placed between the wo halves, filled with the required solutions and closed by means of two ground joints greased with ilicone.

The oxygen determinations on the solutions were made by the Winkler method as modified by Krogh[4].

The compartment on the inside of the skin was filled with Ringer solution to which vasopressin was added in some experiments in order to increase the sodium transport and hence the oxygen consumption. During the actual experiment the compartment on the outside of the skin is filled with Ringer solution. In this way, the sodium transport can be recorded by reading the short-circuiting current, and the oxygen contents of the solutions can be determined before and after the experiment. This procedure gives the total oxygen consumption and sodium transport.

However, one cannot expect that all the oxygen will be used for active transport of sodium, and the oxygen consumption was therefore also measured when no sodium transport occurred. This is done most easily by removing the sodium ions from the outside compartment by replacing the Ringer solution with distilled water. The oxygen then consumed by the skin is not used for sodium transport and may be subtracted from the total oxygen consumption as a blank.

Control experiments were performed before and after the sodium transport experiment. All the measurements were made on the same skin, and the skin was cut free and weighed after the last control period. Oxygen consumption and sodium transport were both expressed in µequivalents/hr. in order to make them directly comparable. Control runs with the apparatus filled with Ringer solution and secured with silicone grease instead of mounting a frog's skin showed that the oxygen concentration of the solution in the apparatus did not change during 2 hr. (the usual time for an experimental period). This proves that nothing outside the frog's skin interferes with the oxygen consumption.

Some representative experimental results are shown in Table 1. It is seen from column 3 that the total oxygen consumption in µequiv./hr. is often smaller than the number of µequiv. of sodium transported (column 2). The net oxygen consumption is 20–25 per cent of the sodium transported (column 6), that is, for each additional oxygen atom consumed, eight to ten atoms of sodium can be transported. The last column indicates the oxygen consumption in millilitres per gram of the wet weight.

Stapp[5] defined coulomb efficiency as

$$\frac{\text{total coulombs generated by skin}}{\text{coulomb equivalents of total oxygen}}$$

This ratio expresses, as we now know, the amount of sodium transported per gram equivalent of oxygen used. Stapp found in frog skins that were partially short-circuited by means of an external conductor coulomb efficiencies varying from 10 to 65 per cent, and he was surprised at this high value.

Linderholm[2] calculated the coulomb efficiencies from mean values of current and oxygen consumption in a large series of experiments; he arrived at a figure of 82 per cent for the short-circuited skins. This result is not in contradiction with the results

Table 1

Date	Active sodium transport (µequiv./hr.)	Total oxygen consumption (µequiv./hr.)	Net oxygen consumption (µequiv./hr.)	Coulomb efficiency (per cent)	Net oxygen consumption, as per cent of active sodium transport	Oxygen consumption (ml.gm.$^{-1}$hr.$^{-1}$)
March 9	10·8	6·95	2·57	155	23·8	–
April 4	6·50	5·33	1·65	122	25·3	0·118
April 5	5·87	7·16	1·42	82	24·3	0·155
April 19	10·0	6·47	2·51	155	25·1	0·163

given in Table 1. These results were observed mainly with skins with a high sodium transport, in some cases obtained by adding mammalian posterior pituitary extract. It may be added that in experiments with skins that were not short-circuited, Linderholm found an average coulomb efficiency greater than 100 per cent.

The present experiments show that more than one equivalent of sodium is transported for each equivalent of oxygen taken up. The coulomb efficiencies observed by Stapp and in some experiments by Linderholm were less than 100 per cent, and this led Linderholm to assume a one-to-one sodium to oxygen relationship. Since, however, the epithelial layer, which is presumably responsible for the sodium transport, represents only one-sixth of the skin weight, such an assumption would require an unreasonably high oxygen consumption in this layer, even if all the oxygen were used for sodium transport.

It is possible that the oxygen consumed by the skin during the control periods (no transport of sodium) may be used for sodium transport when sodium becomes available, the net oxygen consumption being thus only an extra consumption. In this case the amount of oxygen utilized for the transport of one equivalent of sodium will be somewhere between the net consumption and the total consumption. Whether this will fit into the theory advanced by Conway[6] may be a question of interpreting his symbols. The low relative oxygen consumption does, however, suggest that more than one step of the oxidative metabolic cycle is involved in the transport of sodium.

A more detailed report of this work will appear in *Acta Physiologica Scandinavica.*

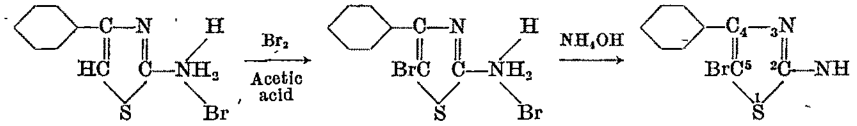
Non-metallic Fungicides

In the course of investigations on the synthesis of 2-amino-4-aryl thiazoles and their derivatives, it was decided to examine their fungicidal properties, as they contain a cyclic grouping, —N—C—S—, which is present in the structure of some of the well-known fungicides[1], and the presence of lipophilic and polar substituents like aryl- and amino-groups in the thiazole nucleus is expected to increase the fungitoxic properties of the thiazoles as reported earlier[2]. The recent use of some thiazole derivatives as fungicides[3] has greatly stimulated work in this direction. The introduction of halogens into the benzene and other aromatic nuclei of various phenolic compounds greatly increases their fungicidal properties[4], and as bromo-derivatives are often more potent than the chloro-compounds, it was thought worth while to introduce bromine into the thiazole nuclei with the hope of augmenting their fungicidal and other activities. In the present communication seventeen different 2-amino-4-aryl (phenyl; p-tolyl p-ethyl phenyl; p-methoxy and p-ethoxy phenyl β-phenylethyl and β((p-methoxy)phenyl)ethyl; 2 : dimethyl phenyl and 3 : 4 dimethylphenyl; α- an β-naphthyl; o- and p-hydroxy phenyl; m- an p-amino phenyl; p-bromo phenyl and 2-thienyl thiazoles have been prepared by the method of Kin and Hlavacek[5] by allowing different aryl methy ketones to react with thiourea in the presence c iodine. These compounds have been brominated witl bromine in acetic acid medium after protecting th amino-group either by converting it to the hydrobromide salt or by acetylating it. In all these case bromine entered position 5 of the thiazole nucleu The position of bromine was ascertained by th inability of such compounds to undergo couplin with diazotized aniline, which usually takes place a position 5[6] if it is free.



All the seventeen bromo thiazoles have bee screened for both fungicidal and bactericidal actio For fungicidal assay, the method of Montgomery an Moore[7] was used. *Piricularia oryzae* Cav., th causative organism of rice blast, was used as the tes fungus. The compounds 4(p-hydroxy phenyl), 4(α naphthyl) and 4(p-bromo phenyl), 5-bromo thiazole completely inhibited spore germination at concentrations of 20, 20, 22 p.p.m. respectively, and at concentrations of 10, 12, 10 p.p.m., spore germinatio was only 50 per cent. The unbrominated thiazole inhibited spore germination at a concentration c 90 p.p.m.

The Rideal–Walker serial drop dilution metho was used for the study of the antibacterial activity The test organism was a 24-hr. culture of *Staphyl coccus aureus.* While some of the unbrominate thiazoles were active in 1 : 8,000 (*M.E.D.*) dilutio 4(m-amino phenyl), 4(p-ethoxy phenyl), 4(α-naphthy 5-bromo thiazoles showed activity in 1 : 20,00 (*M.E.D.*) dilution, and 4(β-naphthyl), 4(β-pheny ethyl) 5-bromo thiazoles showed activity at a dilutio of 1 : 15,000.

Details of this work will be published elsewher I thank Dr. M. K. Rout, reader in chemistry, fo his interest and help in the work, and Mr. S. Y Padmanavan, mycologist of the Central Rice Researc Institute, Cuttack, for supplying the culture of th test fungus for the fungicidal work.

Potassium Ion Stimulation of Hydrocarbon Oxidation by a Soil *Corynebacterium* sp.

The oxidation of straight-chain aliphatic hydrocarbons by a soil *Corynebacterium* sp. has been described previously[1]. The present communication demonstrates that the rate of hydrocarbon oxidation by washed suspensions may be stimulated markedly by potassium ions, which, however, have little effect on the oxidation-rate of possible intermediates.

Suspensions of the bacteria were grown either in a synthetic glucose broth deficient in potassium ions, or in nutrient broth, *p*H 7·0, incubated two to three days at 26° C. on a shaking machine. The synthetic medium had the composition 10 gm. glucose, 3·0 gm. ammonium nitrate, 1·5 gm. diammonium hydrogen phosphate, 0·25 gm. magnesium sulphate, 0·1 gm. calcium chloride, trace amounts of ferrous, zinc, cupric, manganese and molybdate ions per litre. The harvested cells were washed once with distilled water, shaken overnight at 26° C. to reduce endogenous respiration, centrifuged and resuspended in distilled water (1 ml. suspension equivalent approximately 1·0 mgm. total cell nitrogen). The hydrocarbons were obtained from L. Light and Co., Colnbrook, England. Respiratory exchanges were measured by the Warburg technique at 27° C. in 0·02 *M* tris (hydroxymethyl) amino methane buffer *p*H 7·0. 0·05 ml. hydrocarbon was added from the side-arm.

The effect of potassium ions (0·0008 *M* final) was tested on the rate of oxidation of *n*-hexadecane, *n*-tetradecane and *n*-decane by suspensions of *Corynebacterium* sp. harvested from potassium-deficient media. There was an initial lag period of low oxygen uptake during which potassium ions caused a slight but consistent inhibition of the oxidation-rate. The lag period varied from 1 to 2 hr., depending upon the hydrocarbon oxidized. There followed a marked stimulation of the rate by the added potassium ions. The respective overall oxygen consumptions in the presence of the C_{16}, C_{14} and C_{10} paraffins were stimulated 231, 108 and 122 per cent by 0·0008 *M* potassium ions in 7 hr. No further stimulation was obtained by adding ten times this concentration of potassium ions. *n*-Octane was oxidized much more slowly, but after 7 hr. a net oxygen uptake of 125 µl. in the presence of potassium was observed, compared with 43 µl. in its absence.

The effect of other monovalent cations on hydrocarbon oxidation by potassium-deficient cells was investigated. 0·0008 *M* ammonium ions, after 6½ hr. incubation, stimulated *n*-hexadecane oxidation even more than potassium ions (225 compared with 168 per cent). Rubidium ions were less effective (138 per cent). Caesium, sodium and lithium ions had no significant effect.

Similar results were obtained with *n*-decane as substrate, except that 0·0008 *M* ammonium ions had no effect upon the oxidation-rate, and rubidium ions only stimulated after 5 hr. incubation. In a separate experiment, however, it was shown that 0·008 *M* ammonium ions, after 4 hr., stimulated *n*-decane oxidation 111 per cent compared with 114 per cent stimulation by an equivalent of potassium ions. Rubidium ions (0·008 *M*) again stimulated only after a lag period (35 per cent in 4 hr.).

The monovalent ions were added as their chlorides. The stimulation achieved is due to the cation, since identical results were obtained with equivalent amounts of potassium chloride, sulphate and nitrate.

Table 1. STIMULATION OF *n*-DECANE OXIDATION BY POTASSIUM IONS USING FRESH AND LYOPHILIZED CELLS OF *Corynebacterium* SP

Period of ageing cells at 4° C. (days)	Fresh cells			Lyophilized cells		
	Oxygen consumed (µl.)		Percentage stimulation	Oxygen consumed (µl.)		Percentage stimulation
	Decane + 0 008 *M* K^+	Decane only		Decane + 0 008 *M* K^+	Decane only	
0	339	282	20	307	220	40
1	346	287	21	285	159	79
3	335	280	20	270	134	102

Each cup contained cell suspension ≡ 0·52 mgm. cell nitrogen (non-lyophilized cells), or 0·42 mgm. cell nitrogen (lyophilized cells) in 2·5 ml. 0 01 *M* (final) 'tris' buffer *p*H 7·0, incubated at 27° C. for 3½ hr.; 0·1 ml. *n*-decane was added from the side-arm.

The stimulation of hydrocarbon oxidation by potassium ions may be demonstrated in another way. Lyophilized cells of *Corynebacterium* sp. grown in nutrient broth showed a marked increase in potassium stimulation of *n*-decane oxidation, when aged in 0·025 *M* 'tris' buffer, at 4° C., compared with identically treated cells of the same suspension which had not been freeze-dried (Table 1).

The effect of potassium ions on the rates of oxidation of the aliphatic monohydric alcohols (range, ethanol to *n*-undecyl alcohol) and of the monocarboxylic acids (range, acetic to *n*-decylic acid) by potassium-deficient cells was investigated. 0·0008 *M* potassium ions had no effect upon the oxidation-rates, although identical concentrations of the cation caused a 244 per cent stimulation in 6½ hr. of oxidation of *n*-hexadecane by the same suspension. If the potassium ion stimulation of hydrocarbon oxidation is a direct effect upon one of the enzyme systems involved, then it would appear it must exert its influence before the formation of likely intermediates such as the fatty alcohols and acids. Further work with cell-free extracts is proceeding to this end.

Magnetically Induced Vortex for Small-scale Aerated Culture Studies

The advantages of aerating liquid cultures of bacteria to enhance the yield are well known. The use of sparger aeration techniques on a small scale is subject to certain disadvantages due to difficulties in sterilizing the air supply and controlling the frothing of the medium—particularly when it contains serum.

Aeration by the production of a vortex in the medium has been described by E. B. Chain *et al.*[1]. This method provides a simple means of finely dispersing the air bubbles and at the same time automatically controls frothing. On a small scale such a vortex can easily be induced by means of a magnetic stirrer, thus obviating the necessity for sterile stirrer paddles and shaft seals. No forced air supply is required, the exchange through a conventional cotton-wool plug being sufficient for the organisms so far cultivated.

We have employed this method for the pilot-scale production of suspensions of *Pasteurella septica*, 'Insein' strain[2], for vaccine investigations. 1,200 ml. amounts of 'Tryptose' broth (Difco) at *p*H 7·3 were sterilized in 4-litre boiling flasks, a magnetic stirrer bar being enclosed with the medium. The flasks were inoculated with 1 ml. of an 18-hr. broth culture of the organism and incubated at 37° C. The medium in the flask was rotated by means of a magnetic stirrer at such a speed that a continuous stream of fine air bubbles was dispersed by the rotating stirrer bar. Growth curves based on bacterial dry weights were plotted. The peak of the logarithmic phase of growth occurred at approximately 18 hr., at which point the bacterial dry-weight content of the medium was 0·1556 gm./100 ml.—equivalent to ten times Brown's tube 5. A non-aerated control contained, at this point, 0·0152 gm./100 ml., indicating approximately ten-fold increase in yield due to aeration.

The state of capsulation of the organisms was determined by microscopical examination of films stained by an indian ink/methyl violet method. There appeared to be no decrease in the size of the capsule in such aerated cultures when compared with films made from infected blood.

This method has also been employed for the cultivation of *Asterococcus mycoides* for antigen production. The medium used was 'Tryptose' broth supplemented with 10 per cent yeast extract and 10 per cent pig serum at a *p*H of 7·6.

A. mycoides appears to be highly sensitive to mechanical agitation during the lag phase of cultivation. It was found to be advantageous to incubate the inoculated flasks for 18 hr. before starting the stirrer, otherwise on some occasions no growth took place. A bacterial dry-weight growth-curve estimation showed that the peak of the logarithmic phase of growth occurred at approximately 24 hr. after commencement of aeration. At this point the bacterial dry-weight content of the culture was 0·0368 gm./100 ml. This figure is similar to the mean of 0·0322 gm./100 ml. previously recorded in sparger aerated culture[3].

A Mutant of *Drosophila* without *Iso*xanthopterine which is Non-Autonomous for the Red Eye Pigments

*Iso*xanthopterine has recently been found in tissues of various anthropods[1,2]. It seems to be a common and regular constituent of normal genotypes of many species. We also found this substance in the following mutants of *Drosophila melanogaster*: *b, bw, ca, car, cd, cl, cn, e,* g^2, kar^2, *ltd, lt,* lz^{cl}, *ma, mah, p,* pn^2, *pr,* rs^2, *se, sed, st, v, w,* w^a, *y*. In certain genotypes such as *w* and *bw*, however, the *iso*xanthopterine disappears from the body[2] during the first days of imaginal life.

By studying the inventory of substances obtained from a new mutant with reddish-brown eyes, we discovered that this genotype of *Drosophila melanogaster* does not at any stage of development contain *iso*xanthopterine. This biochemically exception mutant was isolated from one of our laborato stocks; for the respective gene we determined t locus 51 ± 1 in the third chromosome. We th searched for known Mendelian eye-pigment facto within this chromosomal region and found that little-known mutant, *rosy* (*ry*), which was discover and approximately located by Bridges[3], correspon phenotypically and genetically with our mutant, f which we now use the term "*rosy*^{2}" and the symb ry^2. The F_1 hybrids ry/ry^2 have the same reddis brown eyes as both their parents, and they, t do not contain *iso*xanthopterine.

Table 1 FLUOROMETRIC VALUES OF THE RED PIGMENTS OF SIN EYES IN ARBITRARY UNITS

Exp	Host	Implant	*n*	Mean and its standard error	
				Host	Implant
I *a*	+ ♀	+	16	27·0 ± 0·75	14·5 ± 0·8
b	+ ♂	+	18	22·3 ± 0·80	12·3 ± 0·5
II *a*	ry^2 ♀	ry^2	10	8·3 ± 0·71	6·8 ± 0·5
b	ry^2 ♂	ry^2	4	5·25 ± 0·64	5·25 ± 0·4
III *a*	+ ♀	ry^2	10	26·77 ± 0·50	15·0 ± 0·8
b	+ ♂	ry^2	14	23·33 ± 0·75	13·29 ± 0·7
IV *a*	ry^2 ♀	+	12	10·25 ± 1·09	7·69 ± 0·7
b	ry^2 ♂	+	11	6·91 ± 0·58	5·0 ± 0·4

In addition to the mutant eye colour and the la of *iso*xanthopterine, there are some further featur characteristic of our *rosy*^{2} allele. The Malpighi tubes become inflated, and they contain in the lumens large inclusions of a yellow- to orange-colour excretion material. The viability of our ry^2 sto is reduced at 25° C.; 30–60 per cent of the imagin die either before, during or shortly after hatchi from the puparium. Thus ry^2 behaves as a *P* semilethal[4].

The reddish-brown eye-colour is due to a conside able reduction of the red pigments, and in the co binations $cn/cn, ry^2/ry^2$ or $v/v, ry^2/ry^2$ the eyes beco orange, owing to further lack of the brown omm chrome pigments.

By transplanting eye disks and other larv primordia, we have studied the inventory of fluore cent pigments of ry^2 organs after their developme in normal hosts (+) and vice versa. Each met morphosed transplant was chromatographed and i fluorescent substances compared with correspondi organs of the host and untreated controls. In th way the amount of pigment was determined fluor metrically on the chromatographic paper by a meth used earlier[5]. A group of representative experimen is summarized in Table 1.

Table 1 shows the following results: (1) A tran planted abdominal eye usually does not form much red pigment as an *in situ* eye of the san genotype (Exp. I and II). (2) Eye disks of ry^2 beha non-autonomously in wild-type hosts (+); they c form as much red pigments as transplanted + ey in + hosts (Exp. III and I). (3) Transplanted + ey do not behave autonomously when developing in r hosts; their pigment formation is inhibited by t mutant host (Exp. IV and I).

It was further shown that ry^2 eye implants nor ally become pigmented not only in + hosts but al in *bw, ca, cn, ma, mah, p,* rs^2, *se, w* and w^a.

We then found that the (unknown) substance substances which ry^2 host eyes need in order become normally pigmented can be supplied especial by implanted larval fat bodies and Malpighian tub of ry^+.

A second biochemical character of ry^2 also behaves non-autonomously. Implanted Malpighian tubes, fat bodies, testes and eyes from a + donor cause, in ry^2 testes, the formation or at least the accumulation of *iso*xanthopterine.

The investigation of the gene-conditioned synthesis of *Drosophila* eye pigments has hitherto been much hampered, since most of the colour mutants behaved autonomously as transplants as well as towards fed or injected substances. Only *vermilion* (*v*) and *cinnabar* (*cn*) could be influenced experimentally, so that an analysis of the genic action of the respective loci on the formation of brown ommochrome pigments became possible (compare the well-known work of Beadle, Ephrussi, Clancy, Tatum, Butenandt and others). With regard to the red pigments, however, no suitable mutant with non-autonomous development was known. Thus the *rosy* mutant provides an approach to a developmental and biochemical analysis. A detailed report of our studies will be published in the *Zeitschrift für induktive Abstammungs- und Vererbungslehre*.

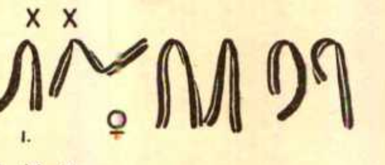
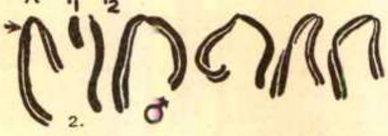
Chromosomes of the Common Shrew

BOVEY[1] reported that two male specimens of the common shrew (*Sorex araneus* L.), from Switzerland, had a sex-chromosome trivalent at first metaphase of meiosis. He did not examine female chromosomes, so was unable to determine whether the sex-chromosome mechanism was $XY_1Y_2 : XX$ (the female having one sex-chromosome *less* than the male) or $X_1X_2Y : X_1X_1X_2X_2$ (the female having one sex-chromosome *more* than the male). Study of four male and two female shrews collected in Britain confirms the presence of a sex-chromosome trivalent in the male and shows that the female has but two sex-chromosomes (XX).





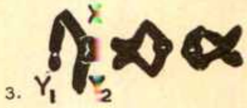


Fig. 1. Female. Two X-chromosomes and the two largest autosomal pairs. × 2,400

Fig. 2. Male. X-, Y_1- and Y_2-chromosomes and the largest two autosomal pairs. × 2,400

Fig. 3. Male. First metaphase showing the sex trivalent and the largest two autosomal bivalents. × 2,400

Three unequal-sized sex-chromosomes are present at metaphase of spermatogonial mitosis (Figs. 2, 5), and these form a trivalent at first prophase and metaphase of meiosis (Fig. 3). These male sex-chromosomes are a large nearly V-shaped chromosome (X), a long rod-shaped chromosome (Y_2) of nearly equal length to the largest arm of X, and a small chromosome (Y_1). In addition, there are two large pairs of approximately V-shaped (metacentric) autosomes, and a number of smaller autosomes. In female bone marrow cells (Figs. 1, 4) two X-chromosomes of identical appearance to that of the male, the two large pairs of metacentric autosomes, and the smaller autosomes are present. The acrocentric Y_2 and the short Y_1 are absent in female cells. A similar $XY_1Y_2 : XX$ sex-chromosome system is known in the marsupials *Potorous tridactylus*[2] and *Protemnoden bicolor* (= *Macropus ualabatus*) (Sharman, G. B., unpublished results) and has also been reported in the rodents *Gerbillus pyramidum*, by Matthey[3], and *G. gerbillus gerbillus* by Wahrman and Zahavi[4].

At prophase of meiosis the trivalent of *Sorex* is composed of two parts, one of which shows the same degree of condensation as the autosomes, whereas the other shows precocious prophase condensation like the sex bivalents of other mammals. We thus conclude that the compound X-chromosome has arisen by a reciprocal translocation between an ancestral X-chromosome and one member of a pair of acrocentric autosomes. Assuming permanency of the end segments of chromosomes (telomeres), this calls for a 'two-break' rearrangement. Presumably one break took place in the homologue of Y_2 and resulted in the loss of an almost terminal centromere, whereas the other took place near the end of one arm of the ancestral X-chromosome. The point at which

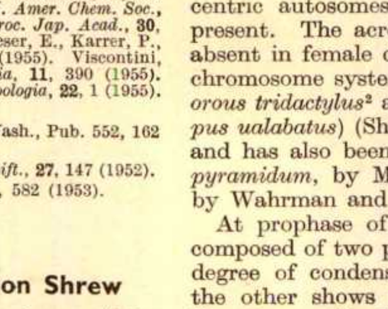

Fig. 4. Female, *S*6. Photograph of a squash preparation of bone marrow pretreated with hypotonic saline. There are twenty-five chromosomes, ten of which are rod-shaped and show a two-armed as distinct from a four-armed structure. × 2,400

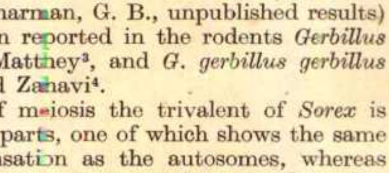

Fig. 5. Male, *S*1. Photograph of a squash preparation of spermatogonium. There are twenty-three chromosomes. Rod-shaped Y_2 overlying metacentric chromosome at 3 o'clock. Four small rods and Y_1 in centre of plate. × 2,400

the broken chromosome ends probably rejoined is indicated by an arrow in Fig. 2. This point can be detected in some mitotic metaphase preparations by the different degrees of condensation of the two types of chromatin making up the compound X. The evolution of the XY_1Y_2 system in *S. araneus* thus appears to parallel the evolution of the same type of system in *Potorous tridactylus*[2], where (in contradiction to White's statement[5]) the mode of origin of the multiple system is clear. A comparison of Bovey's figures[1] with the chromosomes of my material indicates that he has mistaken one of the smaller metacentric autosomes for the X-chromosome. As is obvious from Figs. 1–5, the X-chromosome is among the largest of the set and its origin, as explained above, requires that one of its arms be longer (or at least as long as) the Y_2-chromosome. This is not so in the sex-chromosomes as pictured by Bovey, whose caryograms show the Y_2 (Y_a in his notation) to exceed the combined lengths of both arms of the X-chromosome.

The chromosome number in six specimens of *S. araneus* studied varies between twenty-two and twenty-five. The number of sex-chromosomes is constantly two in the females and three in the males, so that autosomal numbers vary between nineteen and twenty-three. The common shrew, therefore, shows cytological polymorphism, which can be explained on the assumption that what White[6] calls "centric fusions" (that is, Robertsonian changes) have occurred between non-homologous acrocentric autosomes. In all specimens examined there are, almost certainly, thirty-six autosomal arms, some of which are represented either by one metacentric or by two acrocentric autosomes. Apart from the observations of Wahrman and Zahavi[4], intrapopulational chromosomal polymorphism in mammalian species does not hitherto appear to have been reported. Five of the six chromosome counts obtained during this survey were, of necessity, determined from bone marrow preparations, the animals having been captured out of the breeding season. This survey will be resumed in the spring, and these and further observations will be fully reported elsewhere.

This study was carried out at the Medical Research Council Radiobiological Research Unit, Harwell, where, through the courtesy of its director, Dr. J. F. Loutit, I was provided with laboratory facilities while receiving financial support from the Nuffield Foundation. I wish to thank Dr. C. E. Ford for helpful supervision and Dr. Dennis Chitty, of the Bureau of Animal Population, Oxford, for collecting one of the specimens used.

Two Modes of Inheritance of the Short-styled Form in the 'Genus' *Oxalis*

AN investigation to find the mode of inheritance of style-length in the tristylic species *Oxalis articulata* Savign., the gardeners' *floribunda*, was begun in 1949 when the genetic situation in *O. valdiviensis* had been established[1,2]. In the latter species inheritance is disomic; there are two linked dominant genes, that for Short being epistatic to Mid, and the long-styled form is the double recessive.

Data obtained from *O. articulata* revealed a different situation, for when a Long and Mid were crossed reciprocally, both plants having one Short parent, Shorts appeared in their progenies as follows:

	L	M	S	Total
L × M	28	56	35	119
M × L	19	51	41	111
	47	107	76	230

Ten Longs from the M × L progeny were crossed to a Short. In the following year, three of these Longs gave only Longs, 360 in all, and seven gave 452 Longs : 495 Shorts, which fits a 1 : 1 ratio (χ^2 is 1·9525 for 1 degree of freedom). Five Mids from the L × M progeny were selfed; one gave only Mids and Longs and four gave a quarter Shorts, altogether 150 out of a total of 561 plants grown (χ^2 is 0·9037 for 1 degree of freedom).

Although the proportion of Shorts obtained from the reciprocal cross first mentioned is more than a quarter ($\chi^2 = 7·9362$ for 1 degree of freedom) the occurrence of any Shorts suggests that this form is recessive. Had there been any doubt that some unknown factor was influencing this ratio, it would have been removed by the performance in the following year. These data also show that Longs and Mids can be either homozygous or heterozygous at the S locus. Of the fifteen plants tested, four were homozygous where a third were expected. This situation is in complete contrast to that which exists in *O. valdiviensis*. On the other hand, both species are similar in that the short gene, whether dominant as in *O. valdiviensis* or recessive as in *O. articulata*, is epistatic to Mid. It is remarkable that two such different modes of inheritance of the short-style form should exist in the same genus.

O. articulata segregates for pink and white flowers and also has a diluting factor which has no discernible effect on white petals. Linkage of the Short locus and that for pink flower colour has been found. In 1954 eight pink Mids known to be in repulsion (Sp/sP) were crossed to white Shorts (sp/sp). Six of the progenies obtained gave 333 recombinants out of a total of 1,289 plants. The other two progenies were heterogeneous, and, therefore, are not included for the purpose of estimating the recombination fraction. Using the method of maximum likelihood, we find this is 25·8 ± 1·2 per cent.

The situation at the Short locus is similar to that found by von Ubisch[3] in *O. rosea*, although, rather confusingly, she used the dominant symbol for the short allele. She also showed that the loci for short style and pink flowers are linked with 25 per cent crossing-over. Other species tested in this Department are *O. hirta* L., form *E*, *O. tragapoda* Salter and *O. bowiei* Lindl. These three species have been found to have a dominant Short as in *O. valdiviensis*. The results may be summarized as follows:

Dominant Short	Recessive Short *
O. valdiviensis	*O. rosea*
O. hirta L., form *E*	*O. articulata* Savign.
O. tragapoda Salter	
O. bowiei Lindl.	

A more extensive publication elsewhere will be delayed so that inheritance of the Mid form in O. *articulata* may be included. I wish to thank Captain T. M. Salter for collecting and sending the South African species mentioned together with many others, and Sir Ronald Fisher for his constant help and encouragement.

Moult Adaptation in Relation to Long-distance Migration in Petrels

Meinertzhagen[1] has described in South Greenland eas (*c.* lat. 60° N.) flocks of wing-moulting, and often temporarily flightless, great shearwaters (*Puffinus gravis*) which migrate trans-equatorially northward from their Tristan da Cunha breeding grounds lat. 37° 6′ S.). He suggests that it "needs to be explained why the Great Shearwater moults in its winter quarters, whilst the Fulmar (*Fulmarus glacialis*) moults while the young are hatching". (The fulmar, of course, breeds locally.)

In the course of a study[2] of the breeding cycle in elation to the trans-equatorial migration of the hort-tailed shearwater (*Puffinus tenuirostris*) we have accumulated data that have bearing on the point raised above.

Many widely unrelated species undergo a postnuptial moult involving the uninterrupted and more or less serial replacement of the feathers of tail, wings, body and head (for example, the rook, *Corvus rugilegus*)[3]. In other species, such as the fulmar, body moult comes first, immediately followed by the hedding of wing-quills[1,4,5].

During our investigation of *P. tenuirostris* on its Tasmanian breeding grounds, we found that all fifty-hree sexually mature examples examined in the post-uptial phase moulted only on the head and body. Although ovulation occurred in November, flight- and ail-feathers were not replaced before the shearwaters departed in April on their long migration into North Pacific and Arctic waters. It was concluded hat the annual replacement of the feathers most nvolved in flight must be delayed until the termination of this long journey.

Examination of the literature showed that this is ndeed what happens. *P. tenuirostris* has been collected while moulting its wing- and tail-feathers in orthern waters in June and July[6,7]. Further, two ther shearwaters of broadly comparable trans-quatorial movement pattern exhibit a similar post-migratory wing moult. Thus, *P. griseus* has been bserved moulting in wing and tail in the northern hemisphere summer[8,9] and *P. gravis* (as mentioned bove) has been similarly observed by a number of uthors[1,10–13]. An especially remarkable divergence n moult-timing probably occurs even between subpecies. Thus, while *P. puffinus mauretanicus* (which reeds in the Balearic Islands and undergoes only restricted migration or dispersion) carries out the whole of its post-nuptial moult without delay[14], there is a suggestion that *P. p. puffinus* delays the replacement of its flight (but not most of its body) feathers until after crossing the equator to its southern hemisphere 'wintering' grounds[15].

From the above data there emerges clear evidence of the evolution of a moult adaptation related to the migratory requirements of species that undergo a long post-nuptial migratory movement. Moult in all adult shearwaters probably begins during the nesting period; but in trans-equatorial migrants there is a hiatus that allows the retention of the wing- and tail-feathers until after the completion of their post-nuptial journey.

Once the flocks reach their contra-nuptial quarters the moult is completed in a short, sharp burst. The sea is then bestrewn with moulted feathers[7,8] and in the case of one species at least some individuals may be temporarily unable to fly[1]. But the long, arduous journey is now behind them.

The Langmuir Paradox in Discharge Plasmas

In a recent communication, Gabor, Ash and Dracott have described the detection of oscillations in a positive ion sheath separating a section of wall from the positive column plasma of a low-pressure arc in mercury vapour[1]. The oscillations were studied by passing a pencil of cathode rays through the sheath, and were found to have two main components, one with frequencies of up to about 100 kc./s., and the other with frequencies of the order of 100 Mc./s. We have been investigating the fluctuations of similar discharges by the alternative method of withdrawing oscillatory energy through the main electrodes (anode, cathode) and probes to tuned detectors, and have obtained what appear to be comparable experimental results. Our method does not permit of observation over individual periods of a few hundredths of a microsecond, as does Gabor's, but yields a long-time Fourier analysis of the fluctuations.

Accounts have already been published of the lower-frequency band[2]. It has some nearly monochromatic components, but consists mostly of 'noise' with an almost flat spectrum of intensity per unit frequency band versus frequency. The latter can be accounted for by the occurrence of pulses of ionization with appropriate time-constant superposed on the main steady ionization in the discharge. It can be largely prevented from reaching a probe by making the latter negative. It originates where sections of the discharge are unstable, particularly in the cathode sheath when this contains a potential minimum[3]. Its presence does not appear essential for maintenance of the discharge.

The high-frequency band has also been found to have a nearly flat spectrum, between about 15 Mc./s., below which it is usually masked by the more intense lower-frequency noise, and 120 Mc./s., the highest frequency we have studied. The energy which can be withdrawn is almost independent of probe potential, and roughly of the order of magnitude to be expected from the random thermal motion of electrons in the plasma ; we have not been able to make an exact comparison with the electron-thermal noise, owing to uncertainty as to what equivalent resistance is to be attributed to a plasma in this connexion. This high-frequency 'noise' may be related to the sheath oscillations reported by Gabor *et al.*, the fields of which have maximum amplitude at the wall, that is, in our case, the probe surface. They remark that both the amplitude and the frequency of the oscillations were variable, particularly the former, and that the oscillations were not necessarily coherent over an area of wall sheath ; the frequency spectrum will therefore be broad, although it is not certain that it would be as flat as we have found the high-frequency 'noise' spectrum to be.

It seems to us uncertain that a 'Langmuir paradox' necessarily arises near a hot cathode, where fast primary electrons from the thin space-charge sheath on this electrode are present. These may regenerate the high-energy tail of the main plasma group of electrons in two ways if this is being lost to the wall : first, by collisions with the gas molecules, and secondly and possibly more efficiently, by means of high-frequency oscillations in the primary beam and volume of the plasma. Whatever the mechanism of these oscillations may be, they are definitely associated with considerable randomizing of the primary beam in both energy and direction[4].

Isosterism and Molecular Fourier Transform : Crystal Structure Determination of 2-4-Dihydroxybenzoic Acid as related to that of 2-Hydroxy-4-aminobenzoic Acid

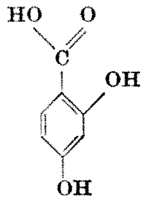
ISOSTERIC organic compounds, that is, compound differing only in the nature of one more atom o substituent groups, often crystallize in quite differen lattices. Using the older X-ray techniques, knowledge of the crystal structure of one member of a isosteric pair may thus be of little help in solvin the structure of the other member ; but the ne Fourier transform techniques[1] allow the investigato to take full advantage of such a situation. This i especially easy if the molecules happen to be plana and centrosymmetric, or if they associate to for centrosymmetric groups.

Table 1

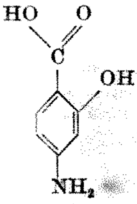
	a	*b*	*c*	*α*	*β*	*γ*	*Z*	Space group
2-4-Dihydroxybenzoic acid*	7·05	9·67	11·81	98° 50′	109° 28′	91° 43′	4	C^1_i–$P\bar{1}$
2-Hydroxy-4-aminobenzoic acid	7·28	3·82	25·33	—	103°	—	4	$C^5_{2h}P2_1/c$

* A number of water molecules ranging between ½ and 3 per mole of compound is given in the literature (see "Beilstein", **10**). W have, however, been unable to find any water in the crystal. This result has been confirmed by analysis, and it seems likely that the loss of weig due to the easy decarboxylation of this compound might be responsible for the erratic results reported in the literature.

An example of this method of analysis is th determination of the crystal structure of 2-4-dihydroxybenzoic acid (I), a compound which is isosteric with 2-hydroxy-4-aminobenzoic acid (II).



(I)



(II)

The crystal structure of the latter had already bee established[2] when it was decided to investigate th structure of the former. The unit cells of these tw compounds are quite different (Table 1), (II) bein monoclinic and (I) triclinic. Structure II had bee found to contain centrosymmetric dimers linke together by hydrogen bonds. The same pairing wa therefore also expected to occur in (I), in which cas the space group was likely to be $P\bar{1}$. This was con firmed, first by the absence of any piezoelectri effect, and later by plotting the intensity distributio of $0kl$ reflexions ; this distribution was of the hype centric type[3], actually indicating the presence centres of symmetry additional to that required b the space group $P\bar{1}$. As there are four molecules i the unit cell, this implies two centrosymmetric dime related by the centre of symmetry of the space grou

To find the arrangement of the molecules in th unknown structure (I), the Fourier transform of th known molecular structure (II) was calculated b sampling the electron density distribution projecte on 010 and correcting it for the tilt of the dim with respect to this plane. Two weighted reciproc lattice sections were now prepared from the $h0l$ an $0kl$ intensities of (I). With the help of a simple devi (described elsewhere by one of us[4]) the calculate transform was projected in turn on each of the

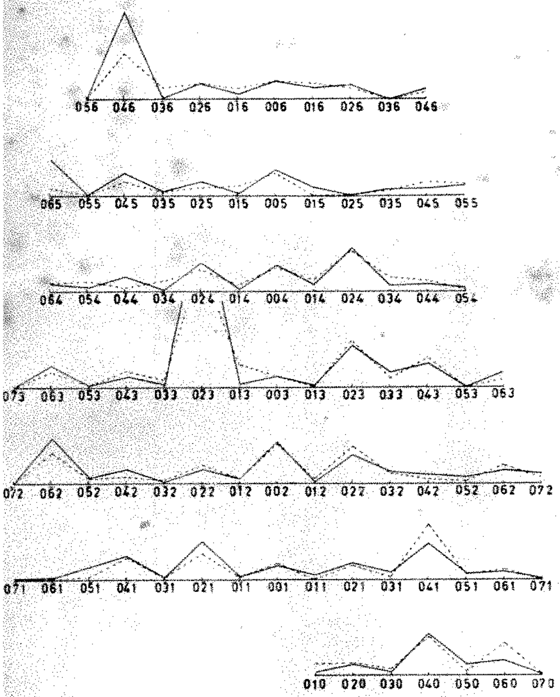


Fig. 1. Comparison between experimental amplitudes F_{0kl} (dotted line) and sampled values of the Fourier transform corrected by the fringe function (full line)

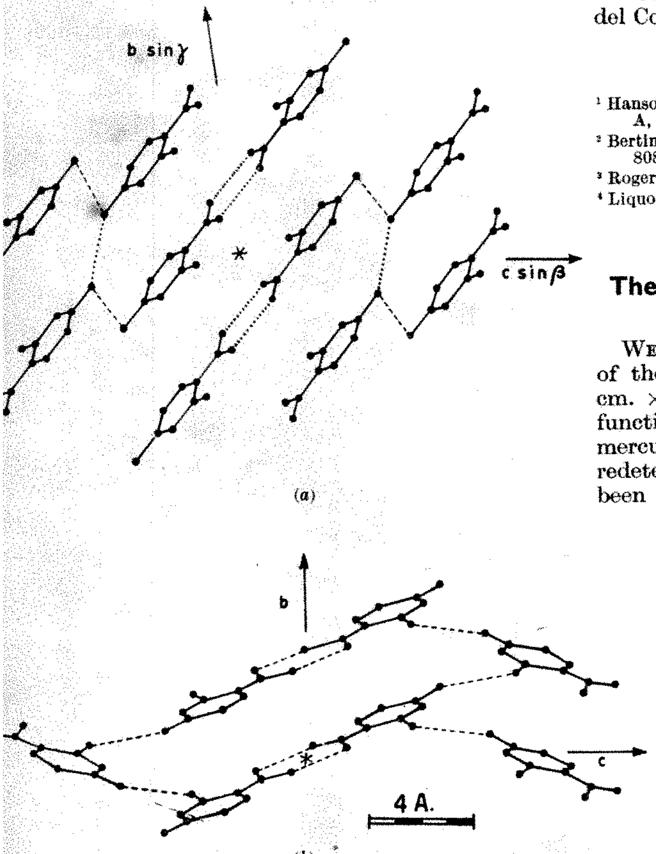

(a)

(b)

Fig. 2. Schematic drawing of the packing of molecules in the unit cell of (a) 2-4-dihydroxybenzoic acid and (b) 2-hydroxy-4-amino-benzoic acid

sections, and molecular orientations giving the best fit were found by trial. At the same time the nodes of the fringe function relating the centres of the two dimers could be recognized from a characteristic trend of the $0kl$ reflexions, giving these centres the approximate co-ordinates of $0\ \frac{1}{4}\ 0$; $0 - \frac{1}{4}\ 0$. On further refinement the centres had to be displaced slightly from these positions. After this had been done, and the sampled transforms had been corrected by a suitable fringe function, the agreement shown in Fig. 1 was obtained for the $0kl$ reflexions, which may be considered good enough to establish the packing of the molecules in the unit cell with a fair degree of accuracy (Fig. 2).

The packing turns out to be quite different in the two isosteric compounds, despite their common tendency to form hydrogen-bonded pairs. Further analysis of the differences between the two structures was not pursued, because considering the similarity in their physico-chemical properties, such differences would be expected to be very small.

We wish to thank Prof. Giacomini for putting at our disposal an apparatus to test the piezoelectric effect, and the Rockefeller Foundation for a grant to one of us (A. R.). We are also indebted to Dr. M. F. Perutz for a critical reading of the manuscript.

The First Townsend Ionization Coefficient for Hydrogen

We have completed independent measurements of the first Townsend coefficient α/p_0 (ionizations/cm. × mm. mercury at 0° C.) for hydrogen as a function of the parameter E/p_0 (volts/cm. × mm. mercury at 0° C.). In view of the several partial redeterminations of this quantity that have recently been reported, we feel that early mention of our results may be of interest.

The results are shown in Fig. 1, where α/p_0 is plotted against p_0/E. Those by Rose are taken at pressures $0{\cdot}5 < p < 45$ mm. mercury, and those by De Bitetto and Fisher at pressures of 100 and 200 mm. mercury. Throughout the range $0 < p_0/E < 0{\cdot}045$, α/p_0 can be represented within the experimental error (± 2 per cent) by the function:

$$\alpha/p_0 = 5{\cdot}1 \exp(-139\, p_0/E)$$

Outside this range, the curve passes through the following points: ($0{\cdot}050$, $4{\cdot}6 \times 10^{-3}$); ($0{\cdot}055$, $2{\cdot}1 \times 10^{-3}$); ($0{\cdot}060$, $8{\cdot}9 \times 10^{-4}$); ($0{\cdot}065$, $3{\cdot}6 \times 10^{-4}$).

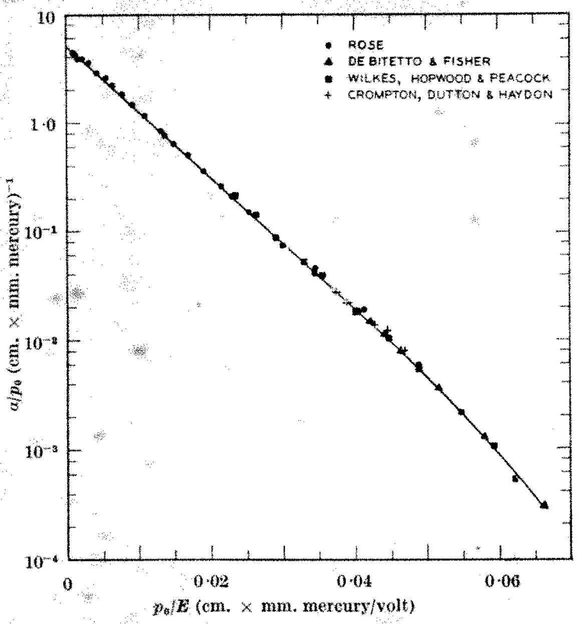

Fig. 1. The first Townsend coefficient α/p_0 (ionizations/cm. × mm. mercury at 0° C.) for hydrogen as a function of p_0/E (mm. mercury at 0° C. × cm./volt)

It is interesting to compare our results with those already published. Before doing so, it is essential that all be reduced to the same temperature, such as 0° C. In this connexion, it is unfortunate that the temperature at which the results are meant to apply is not always explicitly stated.

In the range $0 < p_0/E < 0{\cdot}025$, the present results agree fairly well with those of Ayres[1]; but at larger p_0/E, his results lie substantially above ours. At $p_0/E = 0{\cdot}06$, for example, Ayres gives $\alpha/p_0 \approx 1{\cdot}8 \times 10^{-3}$. Observations taken by Hale[2] extend throughout the range $0 < p_0/E < 0{\cdot}04$; they are higher than ours at both extremes, and lower by a factor $\approx 1{\cdot}8$ at $p_0/E = 0{\cdot}01$. We find excellent agreement with the recent results reported by Wilkes, Hopwood and Peacock[3] ($0{\cdot}027 < p_0/E < 0{\cdot}062$), and also with those reported by Crompton, Dutton and Haydon[4] ($0{\cdot}037 < p_0/E < 0{\cdot}046$). However, results at higher p_0/E reported by Crompton, Dutton and Haydon in an earlier communication[5] lie considerably above ours.

Complete discussions of these and other related observations will appear elsewhere. That part of the work performed at New York University has been supported by the U.S. Office of Naval Research.

Tensile Strength of Liquid Helium II

The tensile strength of a liquid is defined as th maximum negative pressure (P) that a liquid in a isothermal metastable state can sustain before return ing to a two-phase system. Mathematically, thi might be expressed as the value of P at whic $(\partial P/\partial V)_T = 0$, where V represents the volume of th liquid at temperature T. According to Temperley[1] if Van der Waals's equation of state be assumed t hold for a liquid and the condition that $(\partial P/\partial V)_T =$ be applied, the tensile strength may be calculated Benson and Gerjuoy[2], in working with the reduce form of this equation, arrived at :

$$\varphi^3 - \frac{9}{4\theta}\varphi^2 + \frac{3}{2\theta}\varphi - \frac{1}{4\theta} = 0 \qquad (1$$

where $\varphi = V/V_c$, $\theta = T/T_c$, $\pi = P/P_c$ and the sub script c stands for critical value, by applying th condition :

$$\frac{V_c}{P_c}\left(\frac{\partial P}{\partial V}\right)_T = \left(\frac{\partial \pi}{\partial \varphi}\right)_\theta = 0 \qquad (2$$

Values may be assigned to θ and the resulting cubi in φ will give rise to a real root which may in tur be substituted in

$$\pi_{\text{min.}} = \frac{3}{\varphi^2} - \frac{2}{\varphi^3}$$

to give reduced values of the tensile strength.

Consider, for example, the case of nitrogen, whic has $T_c = 126{\cdot}06°$ K. and $P_c = 33{\cdot}5$ atm. Accord ing to equations (1) and (2), the tensile strength shoul be about 109 atm. at 69·3° K. This value is muc higher than that found experimentally both b Misener and Hedgcock[3] in 1953, and by Misener an Hébert in the present work. However, as Temperle points out, this could be due to (*a*) the presence o impurities in the liquid, (*b*) the possibility of variatio with temperature of the constants in the Van de Waals's equation, that is, departure of the equatio of state from a true representation of the state o the liquid.

For helium, with $T_c = 5{\cdot}26°$ K. and $P_c = 2{\cdot}2$ atm., the tensile strength at 1° K. becomes 25·9 atm This value again is much higher than that foun by us.

As Misener and Hedgcock pointed out in 1953, i would seem reasonable that a static method o measuring tensile strength should give rise to tru values, since these are essentially static in characte Accordingly, a modification of their bellows arrange ment, which in turn was an adaptation of Vincent' apparatus[4], was constructed. The apparatus show in Fig. 1 was the working section at the end of 1¼-in. german silver tube suspended in a doubl Dewar flask arrangement. The circular plates, 4 an 5, along with their three interconnecting rods, pro vided a rigid support for the top of both bellows Three more brass rods fixed the lower plates 1 and so that they could move together. When liquid fro the innermost Dewar flask was allowed to fill th top bellows, it could be sealed off by means of th needle valve 6. The latter was controlled from outsid the Dewar assembly by the rotation of a vertica hollow Monel tube welded at the top to a stainle steel threaded shaft. The required seal about th shaft was effected by means of an O-ring. Gas fro a source at controlled pressure was fed through th Monel tube 7 into the lower bellows. As the pressu

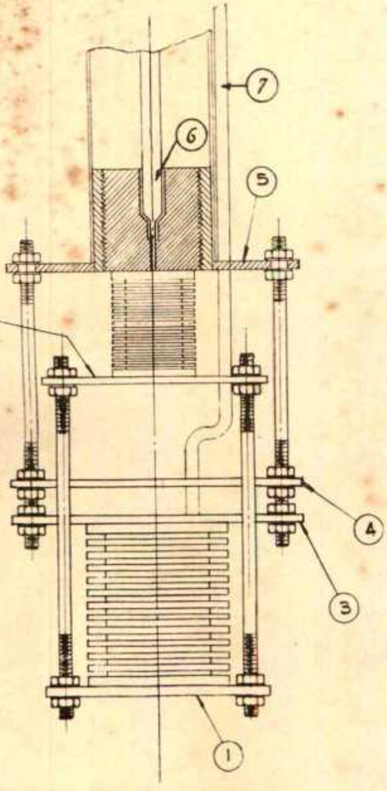

Fig. 1. Pressure-loaded bellows apparatus for tensile strength of liquids

as slowly increased, the level of 2 remained station- y until the maximum negative pressure on the quid in the upper bellows was reached. Beyond is pressure, plate 2 suddenly moved downwards observed through the telescope of a cathetometer. ne value of this maximum pressure was taken to the tensile strength of the liquid in the upper llows.

Since the values obtained in the readings of the s supply were the pressure values above zero-level the lower bellows, the problem of determining the fective cross-section of each bellows was of import- ce. Proceeding in a fashion quite similar to that Vincent, a load F was attached to the lower llows, the upper bellows was left open to atmo- heric pressure, and the load vs. tension found to be 1·37 kgm./ m. Next, gas under known essures replaced the load and a libration of pressure P vs. ex- nsion gave approximately 0·16 m./cm.²/mm. Obviously the ective cross-section A, from F/P, ve 8·56 cm.². As this value rresponded fairly closely to that lculated from the mean outer and ner radii of the bellows (8·73 cm.), was assumed that for purposes of e present experiment, the calcu- ed values of the effective cross- tion of the upper bellows would correct. It followed then that e excess pressure applied to the ver bellows, multiplied by 1·95, uld give the required values of e tensile strength.

As a preliminary experiment, the tensile strength of liquid nitrogen was measured between 64° K. and 76° K. The tensile strength increased with decreasing temperature and the numerical values were substantially in agreement with those found by Misener and Hedgcock, namely, about 3·5 atm. at 71° K.

In liquid helium II at a number of temperatures between 2·147° K. and 1·092° K., no 'break' in the motion of the upper bellows could be observed. As soon as the working pressure was applied, the bellows began to elongate. The rate of elongation was too large to be accounted for by any possible 'film flow' through the closed needle valve. It is concluded, therefore, that if there is any tensile strength at all for liquid helium II, its value as measured by this bellows method is less than 0·3 atm.

We wish to thank the Physics Department of the University of Toronto for the use of the facilities of its Low Temperature Laboratory for this investigation. We would like to thank particularly Dr. H. Hallett and his staff, both for their encouragement and their assistance during the experimental work.

Examination of Fossil Coccoliths in the Electron Microscope

Recently, the use of the electron microscope in investigating the form of fossil coccoliths has been reported by Deflandre and Fert[1], and a preliminary revision of the taxonomy has been given by Braarud, Deflandre, Halldal and Kamptner[2]. The published electron micrographs show little more than the outline of the coccoliths and must be supplemented by examination at lower magnifications with the optical microscope. This unsatisfactory situation is due to the coccoliths being opaque to the electron beam. The difficulty has been overcome by examining shadowed replicas of the coccoliths, which give

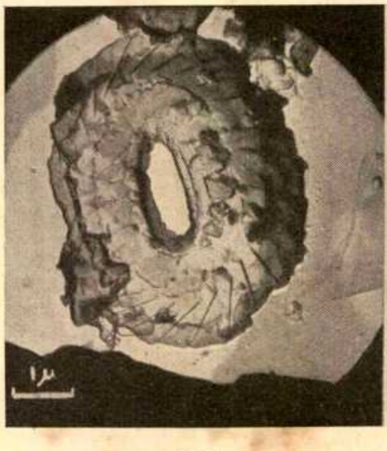

Fig. 1

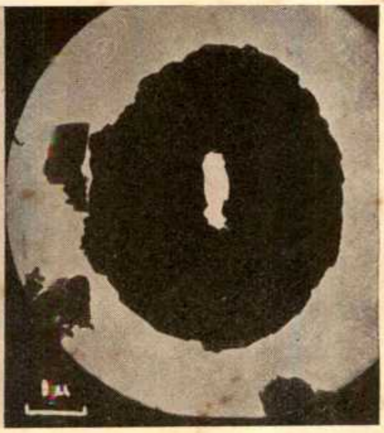

Fig. 2

excellent information about the relief as well as the outline of the coccoliths. The accompanying illustrations compare a shadowed replica (Fig. 1) with a similar coccolith photographed in the transmitted beam (Fig. 2).

The method used in preparation is similar to the silica transfer technique applied by Hall[3] to the study of protein crystals. The replicas of coccoliths were made by dispersing coccoliths, obtained by scraping the rock, in distilled water and supporting this dispersion on a 'Formvar' film. The whole was then coated with a thin evaporated carbon film and the 'Formvar' dissolved in acetone. Finally, the coccoliths were removed with dilute hydrochloric acid and the remaining replica shadowed with gold–palladium.

The method has been applied to coccoliths from the White Band of the Kimmeridge Clay of Kimmeridge, Figs. 1 and 2 being of the dominant coccolith type present. The structure of spirally arranged calcite crystals and central perforation is clearly seen in Fig. 1. It is felt that adequate descriptions of coccoliths should require similar illustration, and that re-examination of existing types by this technique is imperative to establish a satisfactory classification.

Modification of the Bulk Mechanical Properties of Water by Complex Formation in Dilute Solution

A solution of 75 per cent aqueous glycerol shows considerable viscosity (six times that of water) but no structure, so that small bubbles rise to the surface slowly but at a rate predictable from Stokes's law. A 0·07 per cent solution of agar, on the other hand, is only about 4 per cent more viscous than water; but eddies in it are destroyed as rapidly as in the glycerol. Air bubbles rise to the surface in characteristic jerks, and if small enough become trapped. Clearly a certain critical stress has to be exceeded in order to break the molecular framework.

It has now been found that a solution of 0·01 per cent cetyl trimethyl ammonium bromide and 0·005 per cent β-naphthol, added in that order to tap water, resembles the above-mentioned agar solution in its mechanical properties. Its viscosity is only about 2 per cent greater than that of water, eddies are rapidly destroyed and bubbles become trapped. A new feature, however, is the considerable elasticity shown, so that an eddy is not simply damped out but is reversed. Most of the life of a swirl set up in volumes of 500 ml. or less is, in fact, spent in motion in the reverse sense to the initial. With c as the concentration of cetyl trimethyl ammonium bromide in p.p.m., the β-naphthol being at $c/2$ throughout, and t the time in seconds before motion first stops, it was found that the relation $\log t = 0{\cdot}42 + 28/c$ was obeyed between $c = 50$ and 500. The size of the eddy was defined by using 50 ml. of solution in a bottle of 4·3 cm. internal diameter, a rapid swirl being timed with a stop-clock.

When distilled water is used, more material i required, the efficiency of tap water (London) bein part of a general salt effect, probably due to anio adsorption by the complex. Details of the chemistr of this and similar systems are being submitted else where, but the easily controlled 'thickening' of larg volumes of water in this manner should be of interes in hydrodynamic and sedimentation studies.

"Zoonoses in East Africa"

In the report of the recent conference in Kampala Uganda, "Zoonoses in East Africa"[1], I was quote as suggesting that *Trypanosoma rhodesiense* had de veloped from *Tr. brucei* by repeated passages throug *Glossina pallidipes*. My thesis was, in fact, almos the exact opposite of this. I emphasized that a the evidence so far shows that the property o infectivity to man which alone distinguishes *T* *rhodesiense* from *Tr. brucei* is an extremely stabl one and that there has never been a known case o interconversion of these two. On the other hand I pointed out, in any area where *Tr. rhodesiens* had appeared, either it could be traced to direc introduction by infected human beings from a know source, or the other human infective 'species', *T* *gambiense*, had been known to be present in the are for some time.

I stressed the association of *Tr. gambiense* wit the *palpalis* group of *Glossina* and of *Tr. rhodesiens* with the *morsitans* group and indicated that *G* *pallidipes* was consistently present in areas wher *Tr. rhodesiense* had appeared some time after *T* *gambiense*. There are several areas in which, thoug the appearance of *Tr. rhodesiense* might conceivabl have been due to direct transport, it also might hav been due to the conversion of *Tr. gambiense* into th more virulent form, *Tr. rhodesiense*. Such areas ar Busoga in Uganda, Buvuma Island in Lake Victori Uganda, Central Nyanza in Kenya and North Mar in Kenya. *G. pallidipes* occurs in all these area Further, *Tr. rhodesiense* is believed to have originate from the Luangwa Valley in Northern Rhodesia the end of the first decade of this century, whe *Tr. gambiense* was known to have been introduce in the previous two or three years. This area is o of the largest in eastern Africa of a mixed popul tion of *G. pallidipes* and *G. morsitans*.

At the Kampala conference I put forward th hypothesis that *Tr. rhodesiense* has always originate from *Tr. gambiense* and made the tentative suggestio which is supported by small pieces of other evidenc that the conversion to the more virulent huma infective form may have been due to repeate transmission by *G. pallidipes*.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Tuesday, May 22

Wright-Fleming Institute of Microbiology (at St. Mary's spital Medical School, London, W.2), at 5 p.m.—Prof. F. W. gers Brambell: "Transmission of Passive Immunity"* (Almroth right Lecture).

Tuesday, May 22—Friday, May 25

Textile Institute (in the Winter Gardens, Blackpool)—Confer- ce on "New Yarns and Fabrics".

Wednesday, May 23

Royal Society of Medicine, Endocrinology Section (at 1 mpole Street, London, W.1), at 5 p.m.—Annual General Meeting; lowed by a discussion—"Dwarfism and Some Nutritional Factors". ening Speaker: Prof. A. C. Frazer, followed by Dr. C. E. Dent d Dr. S H Taylor.

Eugenics Society (at the Royal Society, Burlington House, cadilly, London, W.1), at 5.30 p.m.—Dr. F. M Martin: "Home ckground and Selection for Secondary Education".*

British Institution of Radio Engineers (at the London School Hygiene and Tropical Medicine, Keppel Street, Gower Street, ndon, W.C.1), at 6.30 p m.—Dr. K. Froome. "The Measurement the Velocity of 'Light' by Electronic Methods".

Society for Analytical Chemistry (joint meeting with the od Group of the Society of Chemical Industry, at the Chemical ciety, Burlington House, Piccadilly, London, W.1), at 6 30 p.m.—ientific Papers

Thursday, May 24

British Institute of Radiology, incorporated with the Rontgen ciety (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), 8 p.m.—Annual General Meeting. 8.30 p.m —Ordinary Meeting, lowed by Prof. F W. Spiers: "Radioactivity in Man and His vironment" (Presidential Address).

Thursday, May 24—Monday, May 28

British Mycological Society (at Flatford Mill)—Spring Foray.

Friday, May 25

Biochemical Society (at Rothamsted Experimental Station, rpenden, Herts), at 10.45 a.m.—Scientific Papers.

ociety for Analytical Chemistry, Physical Methods Group int meeting with the Photoelectric Spectrometry Group, in Physical Chemistry Laboratory, South Parks Road, Oxford), at 0 p.m —Meeting on "Nuclear and Para-Magnetic Resonance".

British Psychological Society, Education Section (at the iversity of London Institute of Education, Malet Street, London, C.1), at 7 p.m.—Mr. H. E. O. James: "Ethnic Prejudices and ir Reduction by Educational Means".

Royal Institution (at 21 Albemarle Street, London, W.1), at p.m.—Prof. Cyril S. Smith: "The Structure of Metals as Seen der the Microscope".

APPOINTMENTS VACANT

pplications are invited for the following appointments on or ore the dates mentioned:

ranslator/Abstractor (with a knowledge of engineering subjects l ability to translate accurately and speedily from at least two eign languages) at the Central Electricity Authority Head-rters, London, S.E.1—The Director of Establishments, Central ctricity Authority, Winsley Street, London, W.1, quoting Ref. /809 (May 25).

ecturer (with a first- or second-class honours degree in chem-y, and special qualifications in physical chemistry) in the School Chemistry—The Director, Robert Gordon's Technical College, erdeen (May 26).

enior Laboratory Technician for work in the Chemistry, ysics and Biology Laboratories—The Secretary, Paddington hnical College, Saltram Crescent, London, W.9 (May 26).

esearch Assistant (with special qualifications in physical mistry, and preferably previous experience in some branch of ymer science) in the Department of Chemistry—The Registrar, University, Manchester 13 (May 28).

hysicists (2) (one with experience in electronics and the other radiotherapy), to work in a laboratory engaged in experimental routine work for the medical staff—The House Governor, King's lege Hospital, Denmark Hill, London, S.E.5 (May 29).

epartmental Demonstrator in Cytology, and a Research ficer in Cytology—Prof. C. D. Darlington, Botany Department, University, Oxford (May 31).

ppenheimer Geological Fellows (suitably qualified graduates recognized universities and institutions) in the Institute of ican Geology—The Registrar, The University, Leeds 2 (May 31).

esearch Assistant to take charge of Electron Microscopy (in-ling electron diffraction)—Prof. R. M. Barrer, F.R.S., Imperial lege, London, S.W.7 (June 1).

Osborne Reynolds Research Fellow (with experience of research in hydraulics and capable of independent work) in Engineering—The Registrar, The University, Manchester 13 (June 2).

Physicist or Mathematician (with a first- or second-class honours degree or equivalent, and preferably with a good knowledge of physical principles underlying engineering design) at a Ministry of Supply Research and Development Establishment near Sevenoaks, Kent, for general physico-mathematical work in relation to the performance and instrumentation of armament components—The Ministry of Labour and National Service Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.163/6A (June 2).

Physicist (with a good honours degree or equivalent) at the National Coal Board's Coal Survey Laboratory in Cardiff, to initiate studies of the physical and mechanical properties of South Wales coal seams—The National Coal Board, Staff Department, Hobart House, London, S.W.1, quoting SS/266 (June 2).

Assistant Lecturer in Mathematics—The Registrar (Room 9, O.R.B.), The University, Reading (June 4).

Lecturer or Assistant (Grade B) (with teaching and research experience) in Geology up to B.Sc. (Special) standard—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (June 4).

Research Assistant in Chemistry (Organic) in connexion with a grant from the British Empire Cancer Campaign Committee, for work on the organic chemistry of nucleotides—The Registrar, The University, Manchester 13 (June 4).

Assistant Lecturer or Lecturer (with special interests in petrology) in the Department of Geology—The Registrar, University College, Singleton Park, Swansea (June 5).

Senior Lecturer (with a research interest in a branch of applied mathematics) in Mathematics—The Secretary, Royal Technical College, Glasgow (June 6).

Lecturer in Bacteriology—The Secretary of University Court, The University, Glasgow (June 9).

Shell Students in Chemical Engineering—The Registrar, King's College, Strand, London, W.C.2 (June 9).

Tutorial Research Student in Mathematics (pure or applied)—The Principal, Royal Holloway College, Englefield Green, Surrey (June 9)

Assistant Lecturer in Organic Chemistry—The Secretary, The Queen's University, Belfast (June 11).

University Lecturer (preferably specialized in statistics) in Mathematics—The Secretary of the Appointments Committee of the Faculty of Mathematics, The Arts School, Bene't Street, Cambridge (June 13).

Sessional Lecturer (preferably specialized in historical, cultural and Eurasian geography) in the Department of Geography—The Chairman, Department of Geography, McMaster University, Hamilton, Ontario, Canada (June 15).

Technician in the Department of Zoology—The Registrar, University College of Wales, Aberystwyth (June 15).

Lecturer in Psychology—Joint Clerk to the University Court, College Gate, St. Andrews (June 16).

Lecturer in Mathematics at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (June 23).

Assistant Lecturer or Lecturer in the Department of Zoology—The Registrar, University College of Wales, Aberystwyth (June 30).

Plant Physiologist; Statistician (Biometrician); Assistant Sylviculturist; and an Assistant Entomologist in the Wattle Research Institute of the University of Natal—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (South Africa, June 30)

Scientific Assistant (with some knowledge of biological, preferably horticultural, research and the ability to make abstracts in clear English from several foreign languages)—Commonwealth Bureau of Horticulture and Plantation Crops, East Malling, Maidstone, Kent (June 30).

Waite Chair of Agricultural Chemistry—The Registrar, University of Adelaide, Adelaide, South Australia (June 30).

Lecturer (with British university qualifications or equivalent, and some experience in teaching geology in a university department of geology and geography) in Geology, at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, July 15).

Director (with wide research and administrative experience and ability to co-ordinate research in the various divisions of the Institute) of the Central Electro-Chemical Research Institute, Karaikudi, South India—High Commission of India, Establishment Department, Aldwych, London, W.C.2, quoting 4/104A (July 22).

Research Assistants (2) (with a good honours degree in physics and adequate research experience) in the Department of Physics, to undertake research on the preparation and properties of infra-red emitting phosphors, under the direction of the Head of the Department—The Registrar, The University, Hull (July 31).

Assistant Master (with a good honours degree) to teach Physics up to advanced and scholarship levels—The Headmaster, Nottingham High School, Nottingham.

Bacteriologist to assist with the control and investigation of sterile procedures in the Blood Products Laboratory—The Secretary, Lister Institute, Elstree, Herts.

Director (with at least a second-class honours degree, or equivalent, with extensive experience in any branch of freshwater biology, biochemistry or soils chemistry) of the Fish Culture Research and Training Institute, Malacca, to be responsible for the overall administration of the Institute and for the direction of the research programme including research into the fundamental processes underlying pond culture, genetics, physiology of breeding, etc.—Director of Recruitment, Colonial Office, London, S.W.1, quoting Ref. BCD.65/23/02.

Experimental Physicist (preferably with a degree in physics or mathematics and previous laboratory experience, or at least G.C.E. advanced level in science subjects, or equivalent), to take charge of the construction and operation of a neutron velocity selector for the new research reactor DIDO—Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 546/34.

LECTURER IN AERODYNAMICS—Head of the Aeronautics Department, Imperial College, London, S.W.7.

LECTURER IN INORGANIC CHEMISTRY and a LECTURER IN ORGANIC CHEMISTRY, at the Wolverhampton and Staffordshire Technical College—Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton.

LECTURER (with a good honours degree and able to prepare students for the B Sc. (Special, London, External) and A.R.I.C. examinations) IN ORGANIC CHEMISTRY—Clerk to the Governors, Luton and South Bedfordshire College of Further Education, 63–69 Guildford Street, Luton, Beds.

LECTURER (with a good honours degree and teaching experience) IN EDUCATION—The Principal, The College, Chester.

LECTURER (with a special interest in organic chemistry, and with research experience) IN CHEMISTRY (Ref. S.1); and an ASSISTANT (Grade B) (preferably with teaching experience) IN CHEMISTRY (Ref. S.2)—The Principal, Hatfield Technical College, Roe Green, Hatfield, Herts.

LECTURER (with good academic qualifications and experience in the food industry) IN FOOD SCIENCE—The Secretary, Royal Technical College, Glasgow.

MASTER (with a good honours degree) TO TEACH MATHEMATICS to advanced and scholarship levels, with some subsidiary physics—The Headmaster, Queen Elizabeth's Grammar School, Blackburn.

METALLURGIST OR PHYSICIST (with an honours degree in metallurgy, physics or related subject) for research in problems of liquid metals, intermetallic compounds, and alloy transformation phenomena as they are related to behaviour in nuclear reactors—Prof. J. G. Ball, Department of Metallurgy, Imperial College, London, S.W.7.

PHYSICIST OR ENGINEER (with a first- or second-class honours degree or equivalent in physics or engineering, and considerable research and development experience in the instrument electronics field or related systems of engineering in the aircraft industry), at the Royal Aircraft Establishment, Farnborough, Hants, to lead a small team on the assessment of guided weapons systems, with particular concern for radar and guidance aspects—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.176/6A.

SCIENTIFIC OFFICERS (with a first- or second-class honours degree, and preferably research experience) IN THE GENERAL PHYSICS DIVISION, for research on controlled thermonuclear reactions—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 532/34.

SENIOR PHYSICS MASTER—The Headmaster, Ellesmere College, Shropshire.

LECTURES AND COURSES

UNIVERSITY OF EDINBURGH

Principal: Sir Edward Appleton, G.B.E., K.C.B., D.Sc., F.R.S.

DIPLOMA IN ELECTRONICS AND RADIO

The one year postgraduate diploma course in electronics and radio will commence on October 9, 1956, and will provide specialized training for those wishing to proceed to research in this field or to employment in industrial organizations. Applicants should hold an honours degree in electrical engineering, mathematics or physics The main lecture courses are in network theory, principles of valve circuits, transmission and radiation theory, and particles in fields. Laboratory and field work will be arranged to support the lecture courses. A limited number of grants can be made available for suitable candidates.

Further particulars and application forms can be obtained from the Assistant Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, 8.

JOHN MacPHERSON,
Assistant Secretary to the University.

NORTHERN POLYTECHNIC

HOLLOWAY ROAD, LONDON, N 7

POSTGRADUATE STUDIES IN CHEMISTRY
PART-TIME COURSE FOR THE M SC DEGREE IN CHEMISTRY

Subjects of study will entail the application of modern techniques to the investigation of organo-compounds of boron, silicon and phosphorus, and students may elect to specialize in organic, physical-organic, physical or inorganic chemistry. Special attention may be given to chromatography including gas phase chromatography.

Graduates and students in their final year of study should apply now for further details.

GRESHAM COLLEGE, BASINGHALL Street, London, E.C 2. Tel. MONarch 2433 Four Lectures by Professor J. L D'Silva, D.Sc, M R C P (Gresham Professor in Physic) on "The Tissues and the Utilization of Oxygen" Tuesday to Friday, May 22 to 25—The Lectures are free and begin at 5 30 p m

OFFICIAL APPOINTMENTS

CHELSEA POLYTECHNIC

MANRESA ROAD, S W.3

DEPARTMENT OF GEOLOGY

Head of Department: W. F. Fleet, M Sc., Ph D (Lond), A R.I C, F.G S

Applications are invited for the post of either Lecturer or Assistant (Grade B) in Geology up to B Sc. (Special) standard Candidates should possess teaching and research experience. Ample time and facilities for research will be provided The present salary scales attached to the grades are as follows:—(a) Lecturer, men, £965 by £25 to £1,065 per annum, women, £799 11s by £20 to £1,065 per annum plus London allowance Placing on the scale will be in accordance with previous service in a similar capacity, (b) Assistant (Grade B), men, £525 to £820, women, £482 3s. to £820, plus additions for training and degree and London allowance of £36 or £48, according to age Placing on the scale will be in accordance with previous service in a similar capacity, and/or industrial experience

Further particulars and form of application may be obtained from the Clerk to the Governors. Applications should be submitted not later than June 4.

UNIVERSITY OF OXFORD

BOTANY DEPARTMENT

The following two posts, providing opportunities for teaching and for research, are available in this department. Both will be for three years and renewable with increments. Salaries £500 to £800 per annum according to age and qualifications, plus F S.S U. (1) Departmental Demonstrator in Cytology, age 25 to 30 (2) Research Officer in Cytology, age 22 to 27.

Apply before May 31, 1956, to Professor C D Darlington, Botany Department, Oxford

---

BIOCHEMIST, GRADUATE, BASIC GRADE, required urgently for research work in relation to steroids. Temporary appointment, for a year in the first instance. Salary, according to qualifications and experience (minimum £475 plus London weighting), and conditions as laid down by Whitley Council for Health Services—Apply, giving names of two referees, to Group Pathologist, Mental Hospitals' Group Laboratory, at West Park Hospital, Epsom, Surrey

---

ATOMIC ENERGY RESEARCH ESTABLISHMENT

HARWELL

has vacancies in the

SCIENTIFIC OFFICER CLASS

for research on controlled thermonuclear reactions. The fields of investigation include the properties of highly ionized gas, spectroscopy, hydromagnetics and electro-magnetism Posts are available for both fundamental and applied research.

A first- or second-class honours degree is essential and research experience desirable

Salary. Appointments will be made according to age, qualifications and experience in the Grades of Principal Scientific Officer, £1,339 to £1,771 per annum. Senior Scientific Officer, £1,174 to £1,339 per annum. Scientific Officer, £555 to £948 per annum.

Contributory pension scheme, five-day week. Excellent working conditions and generous leave allowances

Married officers living outside the Establishment's transport area will be eligible for housing under Authority arrangements or, alternatively, substantial assistance towards legal expenses incurred in house purchase will be available.

Send postcard for application form to Establishment Officer, A E R E, Harwell, Didcot, Berks, quoting reference 2253/532/34

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF PHYSICAL SCIENCES

Applications are invited for the following posts Fellow, Department of Geophysics, Fellow, Department of Nuclear Physics. For the first post practical experience in station seismology and geophysical prospecting is desirable The successful candidate for the second post will be required to work with the 600 KeV or 1 25 MeV Cockcroft-Walton machine or with the 33 MeV Electron Synchrotron The main research projects involve studies of the level structure of light nuclei and studies of the photodisintegration process. The commencing salary and range for Fellows are determined within the limits £A 1,550 to £A 2,200 The appointments will initially be for five years. Thereafter the Fellows will be eligible for permanent appointment. Superannuation on the F S.S U. pattern will be provided and reasonable removal expenses will be paid.

Further details are available from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close on July 2, 1956.

Research Scholarships in all Departments of the University have recently been advertised, particulars are available on request Closing date May 31, 1956 Applications for Scholarships in this School will, however, be accepted up to July 2, 1956

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

Applications are invited for two Lectureships, one light and one heavy electrical engineering, in the Department of Electrical Engineering, to take effect from October 1, 1956. Candidates should possess a good honours degree in electrical engineering, and preferably have completed a graduate apprenticeship, or have had good industrial experience Salary in the range £700 by £50 to £1,000 and upwards, according to qualifications and experience, with F S S U and family allowances Duties will include undergraduate and postgraduate teaching and the undertaking of research.

Applications, stating age, academic qualifications and experience, together with names of two referees, should reach the Head of the Department of Electrical Engineering, Imperial College, London, S W 7, not later than May 31, 1956

THE BRITISH SOCIETY FOR RESEARCH in Agricultural Engineering has a vacancy for a Scientific Officer for work connected with the mechanics of soil cultivation Candidates should have first- or second-class honours degree in mathematics or physics and students graduating in 1956 will be considered Salary scale £514 to £933 according to age and experience. F S.S.U —Application forms from Secretary, N I.A E, Wrest Park, Silsoe, Beds

PHYSICS IN MY GENERATION

a selection of papers by

Max Born

F.R.S.

By selecting some of his popular writings covering a period of 30 years the author has illustrated the process of transformation of the classical philosophy of physics into a modern form which culminates in Niels Bohr's "Principle of Complementarity."

Two of the most widely read of his books show a startling change of attitude to some of the fundamental concepts of science—a change which reflects the enormous advance in our knowledge and understanding of the atomic world during these three decades. They are "Einstein's Theory of Relativity" of 1921, and the American edition of "The Restless Universe" of 1951. The author has taken the introduction of the former as the first item of this collection, the postscript to the latter as its last.

HUMAN MOTIVES IN FUNDAMENTAL RESEARCH

DR. VANNEVAR BUSH'S reports as president of the Carnegie Institution of Washington, besides oting outstanding features of the current research vork of the Institution, have frequently discussed mportant general questions of wide interest such as he relation of the Institution to the Government or he place of the independent research institution. On etiring from the presidency of the Institution at the nd of last December, Dr. Bush devoted the whole f his final report* to considering the real motives in undamental research, asking why we pursue such esearch at all and what it is that unites us in common ffort and urges us on. When we have a group of trong and able men, capable of desiring acclaim and eward from the world in other ways, yet who choose o pursue the path of science, though the individual teps of their advance are often appreciated only by heir immediate associates and the pecuniary rewards r their effort are small, we must look deep for the rue motives.

Emphasizing first that he is concerned with ındamental science—with seeking out the facts of ature and their inter-relations without attempting o apply them immediately to the needs and desires f man for physical comfort, power to control the rces of Nature or freedom from disease—Dr. Bush oints out that the very fact that the pursuit of ndamental science offers side-paths for those who ould follow them is one true and worthy motive beind all that we do. There may be a long interval etween such fundamental work and its practical pplications; but we are conscious, he said, of the roblems with which humanity will struggle long fter present fundamental researches have been erged in the general advance of science, and we are nfident that later generations will complete the ork. Dr. Bush reminds us that we are only just ow learning how the simple organisms, the interplay f which with our organic structure affects our whole ves, operate, and that there is a long path towards complete grasp of their biochemistry and structural ganization, offering many fascinating opportunities r research. Beyond the study of such organic echanisms lies the problem of man's mind itself, s chemical, electrical and structural elements, underanding of which is an essential preliminary to any ue knowledge of ourselves, our possibilities and our mitations.

Dr. Bush goes on to indicate more precisely the ide horizons of fundamental science. Looking at an's present material progress, we can see that he is eaded for catastrophe unless he mends his ways and kes thought for the morrow. It is not simply a atter of the use to which man may put atomic sion or fusion, or a trained virus, and that these omentous questions must be resolved by other patterns of thought than those of long-range fundamental science; or again, that the scientist's deep interest in them is primarily as a citizen and member of the community. His background in science may enable the scientist to counsel wisely with those who apply science or other disciplines; but even apart from wars, Dr. Bush thinks man is still heading for trouble. The world's population is increasing at a rate which renders distress, famine and disintegration inevitable unless we learn to hold our members in check. The resources of the world are being used up at an appalling rate, and new methods of extending the food supply can only postpone the crisis; perhaps they will allow time for communication and education to produce the general understanding essential to a sound solution. While demands for energy can probably be met for a long time to come, the situation is very different with mineral resources, and it will be necessary to place geology, for example, on a firmer scientific basis if we are to continue to find and exploit natural deposits.

It is not suggested by Dr. Bush that in all this we find the sole, or even an effective, motive for fundamental science. Much research, he comments, is done as a matter of habit—a remark which has implications that should be continually examined if effort in research is not to be wasted. Dr. Bush goes so far as to assert that many a research programme is conducted in which the investigator has no clear idea just what he is trying to find out, or what it would mean if he found it, and that men may work for years without stopping to examine critically the relevance of their effort. That is a danger in research against which some precaution should be taken, for to do so is not to banish curiosity as a motive, or even emulation or competition. Indeed, it may well give both a more effective place in scientific motivation by bringing it to some extent under control.

For all this, in Dr. Bush's view, the prime motivation in scientific effort extends far beyond casual and monetary reasons, and even beyond the thought that what we do may, in its small way, benefit the human race in its struggle to control itself and its environment. The scientist, he argues, lives by faith quite as much as the man of deep religious convictions, and he has no doubt that nearly all scientists believe in free will. Although they have built a magnificent structure of materialism, to admit free will into the rigid systems postulated by materialism is to abandon materialism altogether, and in building a theoretical universe based on a system of experiment, observation and logic, the scientist assumes freedom of choice as an act of faith.

No one, Dr. Bush believes, looks on the current scene with more freedom of spirit than the scientists, whose vision is both broad and deep but who at all times must understand the limitations of their methods if they would avoid fallacy and the false application of those methods where they inherently do not apply. Thus, behind all other motives there is, he suggests, a deeper and more powerful one, which for the present can only be expressed in the faith that man can learn to know and to understand, and that it is good to exercise that power and to strive for the extension of our wisdom. This is the primary faith that carries men of science forward in their great adventure, and no other faith is essential. This faith and this sense of participation, acknowledged by scientists only in their rare thoughtful moments, leads them forward, just as it is faith of some kind that has caused men of all callings in all times to strive and to hope.

---

* Report of the President of the Carnegie Institution of Washington the Year ending June 30, 1955. Pp. 9. (Washington, D.C.: Carnegie stitution of Washington, 1955.)

Dr. Bush's interpretation of scientific motivation will be read with respect and with deep interest even by those scientists who do not entirely agree with his interpretation ; and not the least for the moving passage in which he takes leave of his colleagues and, in wishing them the luck which is an essential ingredient of successful scientific careers—C. V. Boys once put it as high as thirty per cent—displays the warm interest, expectation and confidence with which he will continue to watch their work. There, indeed, he hints at a motive that explorers like Scott and Shackleton and Younghusband have notably found among men of science—the spirit of adventure —and Younghusband has put this into words similar to those of Bush. "The human race will never be satisfied until it has completed its knowledge of its surroundings. We want to know everything about this planet, even its furtherest confines, because we not only have to adapt ourselves to our surroundings but in the true spirit of man we have to master them. And we cannot master them until we have full knowledge of them."

This element of adventure alone suffices to impart one of luck or chance, and in considering the organization of fundamental research it is well, therefore, to take account not merely of the factors or conditions which strengthen the motives urging the scientist on his quest but equally those which reduce chance or luck to a minimum by providing the most favourable atmosphere for creative, original work. That is in effect to seek to provide the conditions in which the scientist can most effectively pursue his search for truth. While Dr. Bush does not come very close to Sir Edward Appleton's plea to the British Association for the intrinsic value of science as one of the great human experiences and in that sense rank it among the motives of the scientist, we are brought to much the same conclusion. His address, moreover, has some points in common with discussion of design and chance in discovery and invention by Prof. René Taton, of Paris, in the December 1955 issue of *Impact*. The conditions which stimulate discovery and invention may well be those which promote the free flow of ideas and facilitate, if not new ideas, at least the recognition or reception of new ideas.

Prof. Taton in this article is not concerned with motives, except in so far as they affect the organization of creative scientific and technological work so as to provide the most effective stimulus for the harmonious and fruitful development of science; to this he suggests we ought to be giving very careful consideration. It is obvious that anything we can do to foster or strengthen the motives of scientific research, either fundamental or applied, and still more generally the scientific spirit and outlook, should be an important factor in increasing the numbers of scientists and technologists so widely needed. It might well offer some contribution towards relieving the shortage in Britain of science teachers, which is one essential factor in any long-term expansion seeking to draw in more of the early school-leavers and to direct both boys and girls from the arts side to science.

Prof. Taton's penetrating paper is the more valuable in that, while he gives due weight to the role of chance and accident and even to error, he never over-estimates that part, and he examines even more carefully those antecedents of discovery that are often neglected. Here, and in examining the various types of failure and the influence of philosophical, political, social and economic factors in the environment of the scientist on discovery and invention, Prof. Taton is most stimulating, and his observations stress the conditions which we should seek to ensure for creative work. He suggests, fo example, that it would be worth while for psychologists to study more closely the way in which excessive concentration on a single line of research a preoccupation with ends which obscures possible avenues of reasoning, or the almost unconsciou adoption of a worthless hypothesis or of an unduly sceptical philosophical point of view, have contributed to the failures of even great scientists.

Prof. Taton thus emphasizes a line of inquiry akin to one indicated by Dr. Bush ; but his comments on the obstacles encountered from scientific o philosophical prejudices, and the difficult and unequa struggle in which the authors of many really fruitfu discoveries have had to engage before they could wi recognition, have implications in the social and economic conditions of to-day which need mor attention than they have yet received. At this poin at least, Prof. Taton comes near to discussing motives and, although he does not accept the Marxist theory in suggesting that the choice of a line of researc may be influenced by economic and social factors at least to some extent, he is admitting that motive play a part in selection. Moreover, here he bring out more specifically than Dr. Bush the influence o team-work in research, both fundamental and applied

Only by team-work can much essential research b undertaken or brought to completion to-day. Th task here is to ensure that the conditions in whic creative work is most fruitful and in which scientif motives have full play are preserved and encouraged and that the conditions on which Prof. Taton comments are avoided. Prof. Taton has wisely emphasize some of the dangers which must be minimized i order that the process of discovery and inventio and the flow of new ideas may not be hindered. D Bush, in his valedictory address, however, seems go even deeper, and to reveal the primary faith a motive which it is for the scientist himself to cheris whatever the respect the community may care show for the motives of scientific research.

EXTENSION OF MICROCHEMISTRY

Handbuch der Mikrochemischen Methoden

Herausgegeben von Prof. Friedrich Hecht und Prof. Michael K. Zacherl. Band 2 : Verwendung der Radioaktivitat in der Mikrochemie. Radiochemische Methoden der Mikrochemie. Von Dr. E. Broda und Dr. T. Schönfeld. Messung Radioaktiver Strahlen in der Mikrochemie. Von Dr. T. Bernert, Dr. B. Karlik und Dr. K. Lintner. Photographische Methoden in der Radiochemie. Von Dr. H. Lauda. Pp. iv+423. (Wien: Springer–Verlag, 1955.) 486 chillings ; £6 18*s*. ; 81 D. marks ; 83 Swiss francs ; 9.30 dollars.

SINCE the early days of radioactive studies it was obvious that the new methods allowed physicists o extend their investigation to invisibly small quantities of matter ; the scintillation screen, or the Wilson chamber, made the effects of one single atom isible. A little later it was shown that various ranches of chemistry also could greatly benefit from he sensitivity of radioactive measurements, especially fter the knowledge of the practical inseparability of sotopes could be made use of. A further decisive npulse was given by the artificial production of adioactive isotopes of nearly every chemical element. It is no exaggeration to say that by these advances n entirely new chapter of microchemistry has been pened up, and it is only fitting that the editors of he "Handbuch der Mikrochemie", now in course of ublication, have decided to devote to it the large olume here under review.

The main part of the book is filled by an exhaustive urvey of all the different ways in which radioactive methods have been applied to microchemical studies. ecause of the great range of subjects, the relevant apers are to be found in a great variety of contexts nd in very different journals ; but the two authors ave wielded the scattered material into a clear gical pattern using as the basis of their arrangement ot the nature of the scientific problems investigated, ut—as it should be in a treatise on chemical methods —the techniques applied. Several tests have coninced the reviewer that in this framework every iginal paper in which radioactivity was used for a icrochemical problem has found its proper place, nd that the authors deserve no less praise for the are with which they have collected the material than r their well-thought-out presentation. Considering he number of papers summarized nobody will expect find in their survey many experimental details ; e reader ought to be satisfied to have been guided all relevant original publications. Besides the ble of contents and the index of names and subjects here are, after each of the eleven chapters, surveys the literature discussed which will be a further lp for quick orientation in the vast material.

Although primarily meant as a guide for readers who are looking for the best radiochemical methods solve a special problem, there seems to the reviewer doubt that thanks to the strict logical presentation nd pleasant style of writing this treatise may also used by students who want to acquaint themselves a general way with this extension of microemical methods ; they will find it very helpful that e discussion of the particular methods ('isotopic lution', 'activation' etc.) is preceded by two introctory chapters on "Radioactivity as a Basis of crochemical Methods" and "The Chemistry of dioactive Matter". The authors have achieved the difficult task of writing a comprehensive 'Handbuch' which may also serve as a text-book.

The two much shorter articles which follow the main part of this volume fully maintain the high scientific standard ; they are a very useful supplement on the technical side, as they explain the various methods for the investigation of radioactive rays. In addition to such widely known apparatus as the Geiger–Muller counter, several new devices are described which have probably not yet found their way into many chemical laboratories and of which the scintillation counter is at present the most important. The editors are to be thanked for having enlisted the help of competent physicists in spreading a knowledge, through the medium of this book, of these new pieces of apparatus among chemists. The last chapter, on the employment of photographic methods in radiochemistry, serves the same very useful purpose.

F. A. PANETH

NUMERICAL ANALYSIS

Numerical Analysis

With Emphasis on the Application of Numerical Techniques to Problems of Infinitesimal Calculus in Single Variable. By Prof. Zdeněk Kopal. Pp. xiv+556. (London: Chapman and Hall, Ltd., 1955.) 63*s*. net.

THIS is a stimulating and timely book. Broadly speaking, it covers most of that part of the field of numerical analysis which depends on approximation by polynomials to a function of a single variable—there is no attempt to deal with matrix manipulations, the solution of equations, linear, algebraic or transcendental, or with functions of two or more variables. The book has defects, some of which will be mentioned later, but first it seems desirable to stress the particular merits of the book.

Prof. Z. Kopal goes to considerable lengths to place before the reader all the available methods of attack known to him, without presuming to dictate which formula should be preferred ; this means that the full range of methods is exhibited to a user with unusual requirements, and he can make his own choice. In these days, with the rapid development of automatic computers of various designs, this is an extremely valuable feature. Others who will appreciate this are teachers and instructors of budding numerical analysts.

The attention to the literature of the subject is impressive ; the author has investigated with obvious care a very wide range of references and has incorporated the results of his searches with considerable skill. Then again, the author has noticed a number of outstanding gaps in the development of the subject, and has made notable efforts to fill these or to initiate research on the problems raised. The result is that even experienced numerical analysts will find many things of interest, whether entirely new or offering a new and illuminating approach. For example, I found the description and use of the Hermite interpolation formula, which uses values of function and derivative at *n* points (see pp. 31, 354), and the discussion on the optimum interval for use in the evaluation of derivatives (see p. 104) to be of considerable value. The sections (IV–J, K) on the solution of differential equations by successive extrapolation give another example of the author's own researches, where he is at pains to find recurrence relations, approximating to given differential equations, which shall not introduce—as may so easily happen—accidental complementary solutions that eventually swamp the wanted solution.

Such instances could be multiplied; but it is also of interest to mention some points where I disagree with the author. Often the disagreement is the result of a discussion stimulated by the book, and this is one of its major merits—that it provokes discussion.

On p. 19 the Weierstrass approximation theorem is quoted as a blanket protecting all the methods outlined, with insignificant exceptions. It seems, however, that, when dealing with arguments x at equal intervals, functions such as $(1 + x^2)^{-1}$ or $\exp(-x^2)$ can scarcely be regarded as "insignificant exceptions", and for a fuller understanding of such cases, the cardinal function theory of E. T. Whittaker is needed. On p. 147, it is quite easy to introduce an extra $n!$ in the denominator on the right of (IV–F–13); this can make the difference between a finite and unlimited range of applicability. The preceding two misapprehensions are shared by earlier well-known works. On p. 243, since the equation (V—B—1) is homogeneous, the choice of boundary conditions (V—B—5) as $y(x_0) = y(x_1) = 0$ "for simplicity" is remarkable—it converts an ordinary problem of finding a solution to pass through two points into an eigen-value problem.

The numerical example on pp. 476 *et seq.*, dealing with the numerical solution of integro-differential equations, is unsatisfactory in a number of respects. The table on p. 479 has all values in the last column multiplied by 2; the values in the third column, taken from Chandrasekhar's paper, apply to 4-term Gaussian quadrature, and not to 2-term as stated (non-linearity of the table is obvious on inspection); and in any event comparison of "2-point Gauss" results with "Trapezoidal rule" results is inappropriate—the Trapezoidal rule uses only one point on the average to each interval. Again the table ignores $\mu < 0$, where disagreement is poor, and the discontinuity at $\mu = 0$. Nevertheless, the point to be made is a valid one, provided that there is some way whereby the high accuracy attained for values at the Gauss points can be used adequately in a final computational stage—ordinary interpolation with n points will not do, for it cannot adequately use $(2n-1)$th degree accuracy; the author is not unaware of this.

A further comment concerns Appendix 2 on "Optimum Interpolation". This is a most valuable account which includes a certain amount of current practice not previously available in published form. This appendix has given rise to considerable discussion, from which it has emerged that the statement on p. 61 concerning the modified Chebyshev–Everett formula is not, in fact, unassailable. The assertion by L. Fox, that the factor $-0{\cdot}184$ (or $-0{\cdot}18393$) is usually best, even for Everett-type interpolation, is correct. This question, a rather subtle one, cannot, however, be fully discussed in a review. Another misstatement concerns the so-called—and well-named—"Royal Road" formula. This is on p. 138 after (IV—D—13), where it is stated that "the desired second difference of $y(x)$ at $x = a_{-1}$ turns out to be expressible in the form of a rapidly converging sequence of backward differences of $y^{\text{II}}(x)$ of even orders". In fact, "even differences only" is associated exclusively with central differences, and such a central difference form provides a basis for the well-known methods studied by Gauss, Jackson, Numerov and others. Th backward difference form involves differences of al orders after the fourth, and seems to be new—an what a good idea!

These few points will serve to indicate the man merits of the book, and show that even the errors ar able to provoke healthy discussion.

In my view, the place for this valuable book is o the shelves of general libraries and of the smalle ones attached to computing establishments of al kinds, including those having automatic computers Those who teach or study numerical analysis especially, cannot afford to be without this book—i is a book for teachers and the rather specialist learner The reader will not find many numerical illustrations for these he should use Hartree's "Numerical Analysis"; but this book will not show the wide choice o methods exhibited by Prof. Kopal. The book i very readable, though prolix in parts where it stresse the obvious (it was based originally on lecture notes and this is detectable); in other parts very clos attention is needed. It is a book well worth consulting—and possessing.

J. C. P. MILLER

IMAGE AND ORIGINAL

Operational Calculus based on the Two-Sided Laplace Integral

By Dr. Balth van der Pol and Dr. H. Bremmer
Second Edition. Pp. xiii+415. (Cambridge: A the University Press, 1955.) 60*s.* net.

LET $h(t)$ be a given function defined on the whol interval $-\infty < t < \infty$. The linear functiona

$$L[h(t)] = f(p) = \int_{-\infty}^{\infty} pe^{-pt}h(t)dt \qquad (1)$$

is the *two-sided* Laplace transform or 'image' of th 'original' $h(t)$, as contrasted with the *one-sided* transform got by writing zero instead of $-\infty$ as the lowe limit of the integral. In terms of Heaviside's uni function $U(t)$ (defined to be zero when t is negativ and unity when t is positive) the one-sided is obtaine from the two-sided transform by putting $U(t)h(t)$ i place of $h(t)$ in (1). The domain of p is a strip o the complex plane bounded by two abscissæ, eithe or both of which may be infinite. The main technique of the operational calculus consists of replacin operations on the original by operations on th image. If, for example, this process leads to a expression for the image $f(p)$, the original $h(t)$ i inferred by inverting the integral in (1).

The subject of the book is the two-sided transfor for which the authors claim the following advantages (1) the class of functions suited to an operationa treatment becomes much larger; (2) the transformation rules are considerably simplified; (3) th entire treatment becomes more rigorous than th usual presentation of the one-sided integral in technical books. As to (3), much has been achieved b introducing concepts such as functions of bounde variation, upper and lower limits, and so on, usuall unfamiliar to the engineer and which here recei careful explanation and illustration. The omissio of proofs of some of the basic theorems has bee compensated for by giving references to other boo where they may be found. By such devices exposition a high standard of rigour has been pr served while still allowing room for an astonishingly large amount of illustrative work. Indeed, more than half the text is devoted to applications to differential equations, ordinary and partial, to electric circuit theory, difference equations, integral equations and other topics.

The chapter headings are as follows: (1) general introduction; (2) the Fourier integral as basis of the operational calculus; (3) elementary operational images; (4) elementary rules; (5) the delta or impulse function; (6) questions concerning the convergence of the definition integral; (7) asymptotic relations and operational transposition of series; (8) linear differential equations with constant coefficients; (9) simultaneous linear differential equations with constant coefficients; electric-circuit theory; (10) linear differential equations with variable coefficients; (11) operational rules of more complicated character; (12) step functions and other discontinuous functions; (13) difference equations; (14) integral equations; (15) partial differential equations in the operational calculus of one variable; (16) simultaneous operational calculus; (17) 'grammar'; (18) 'dictionary'.

The first edition was published in 1950. Into the second edition the following new paragraphs have been introduced: rules for the treatment of correlation functions; a note on the theory of distributions; a note on the Wiener–Hopf technique.

The book is written with exceptional lucidity and can be recommended alike to the mathematician and the engineer. L. M. Milne-Thomson

INTERPRETER OF SCIENCE

Science makes Sense

By Ritchie Calder. Pp. 192. (London: George Allen and Unwin, Ltd., 1955.) 12*s.* 6*d.* net.

Mr. Ritchie Calder's latest book can be commended to the participants in the current discussion on scientific language. It is more than a competent and readable piece of journalism; it is a demonstration that the nature and implications of scientific advance can be explained in non-technical language which the ordinary person can readily comprehend, and that this can be done by one who does not himself claim to be a scientist. Moreover, the conditions that must be observed for this to be done successfully are made clear: the scientist must take the trouble to explain to the non-scientist what he is doing and in terms not too specialized; the expositor, for his part, must be willing to listen and must have sufficient background to ask the significant questions. Where this is not done, the attempt breaks down, as may perhaps be seen in the present volume when Mr. Calder is tempted to quote chemical nomenclature. His inaccuracies will irritate the chemist, but they are not serious. They do, however, display a failure on the part of the chemist to convey accurately to Mr. Calder the significance of his jargon and on Mr. Calder's part a failure to consult which is tantamount to neglect of the maxim: "Always verify your references".

Such minor blemishes apart, the book is a real contribution to the popular understanding not only of the great scientific advances of the past half-century but also of the way in which they were achieved. It is an admirable exposition of the nature of scientific thought and method. Moreover, while Mr. Calder's style is lively and picturesque, he holds his imagination in check: in gaining his reader's attention he does not lose a sense of proportion or perspective. The balance and emphasis are almost invariably correct, in spite of the wide field over which he ranges—from the Lunar Society of the mid-eighteenth century to the impact of science and technology on industry and society and the home life of to-day. Five chapters on great discoveries show how they were made, and do so in a way that refutes decisively the idea of magic with which popular thought often clothes the scientist and science.

For that alone the book is worth while. There are minor blemishes: here and there a quantity is false, a wrong note is struck, a word or a phase jars, or (more rarely) a proposition or interpretation could be challenged; these things are not the result of Mr. Calder's flair for the picturesque or of any failure in interpretation, though they may sometimes be due to a sense of values on which opinions may differ. The book should interest the scientist, through the competence of its technique of exposition and scientific and technical accuracy, as much as the story it tells will fascinate the non-scientist. R. Brightman

HISTORY OF ASTRONOMICAL INSTRUMENTS

The History of the Telescope

By Dr. Henry C. King. Pp. xvi+456. (London: Charles Griffin and Company, Ltd.; Cambridge, Mass.: U.S.A. Sky Publishing Corporation, 1955.) 50*s.*

The 456 pages of this excellent book are evidently the result of a truly tremendous amount of research by Dr. H. C. King. The fact that more than sixteen hundred page references are given in nearly as many individual publications further shows the thoroughness and completeness of the factual data.

He starts, in a most satisfying manner, with the earliest device known for the positional observation of the Sun—the sundial—and from there carefully examines each facet of each stage of the optical and instrumental development which culminated in the large present-day telescopes. His style throughout is easy and, in spite of having to be concise, never gives the impression of jerkiness. The book is quite definitely a history of telescopes rather than a history of astronomy, although the two are obviously closely related. As the author points out in the preface, ". . . instrumental improvements receive more attention than the discoveries made through them. The description of Sir William Herschel's 20-foot reflector, for example, occupies more space than his theory of stellar distribution, and far greater importance is attached to the introduction of silvering processes than to the discovery of, say, the planet Neptune".

It would be supremely easy in a book of this sort to dwell at undue length on certain aspects of the subject about which the author is particularly interested or is particularly knowledgeable. Alternatively, it would be simple to become tainted by insularity and make it a book of British achievements in telescopic design, with one or two chapters to cover the efforts of other countries. The author has done none of these things. His review of the subject appears to be very well balanced, the efforts of the scientists and instrument makers of the United States, Britain and the different Continental countries each receiving their due amount of space. It is ironical, but no fault of Dr. King, that the largest two working telescopes in Britain at the time of his going to press were so lacking in novel features that they have correctly received no mention except: "Other large Grubb–Parsons instruments of the thirties are the 36-inch reflectors of Edinburgh and Greenwich . . ."

There are very few points to which the reader can take exception. Perhaps the most obvious of these is the incompleteness of the index. A book of this nature, packed with facts which frequently cannot be placed in chronological order, needs not only a complete index but also one with every possible cross-reference. In particular, it seems that references to instruments in British observatories are least complete. A second point is the omission of a summary of the important dates and events, together with a fairly complete list of observatories with their instruments. Otherwise, I have only noticed trivial errors in the text.

Perhaps naturally, there is little scope for humour in such a book. Consequently, the following remark produced a smile when in another context it might have been overlooked: "After Colby's survey of Scotland, the instrument [a portable zenith sector] was placed for safety in the Tower of London, where it was destroyed in the fire of 1841".

It is difficult to decide whether a history book should stop with the chronicling of all known relevant facts. Historical facts are of the greatest importance; but they become of even greater interest if they are accompanied by a critical examination of events. Why, for example, do certain developments take place at a certain time while other seemingly obvious developments have to wait for many years? Possibly Dr. King feels he has done his part by assembling the facts, and that the deductions are better made by the reader. Of this I am not so certain.

Dr. King deserves the very highest praise for bringing so much work to a stage where one has to look hard indeed to find any adverse comment. The book is well printed on good paper and has just the right number and choice of illustrations and diagrams. The price is not excessive by modern standards, and there is every reason to believe that the future will find this book on the library shelves of all concerned with astronomy, optics or scientific instruments. H. E. Butler

ANALYSIS OF WEATHER CHARTS

Principles of Meteorological Analysis

By Walter J. Saucier. Pp. xvi+438. (Chicago: University of Chicago Press; London: Cambridge University Press, 1955.) 75*s*. net.

Not long ago there were two schools of thought in meteorology: one school held that weather has its origin in the higher atmosphere and is only a by-product of more important events there; the other maintained that the irregular distributions of land and sea, mountain and plain, and heat and cold on the Earth's surface produce our weather systems and that these react on the atmosphere above with an intensity that diminishes progressively with height. Meteorologists now know that changes occur at the top of the troposphere as rapid, as frequent and as violent as those near the surface and are related to them: though the bulk of differential heating and the friction in the atmospheric engine occur at the bottom, the main cogs and flywheels are higher up But no one yet knows how the parts fit together.

Strictly, as a man of science, the meteorologist should eschew attempts to forecast the behaviour of the atmosphere until he has a coherent and properly tested theory of its mechanism: but the optimism of his predecessors, based on inadequate knowledge of the real intricacies of their task, and perhaps also the occasional successes of the weather-lore man, have forced his hand: the meteorologist has had to work empirically, using his hypotheses for forecasting as he goes along. Circumstances have now given him his chance to put things right. To cope with the flood of information about conditions up to great heights that is needed several times a day for aviation, he has sought the help of high-speed computing machines, and to use them he has had to devise models in mathematical terms for describing the simpler features of the atmosphere. These models have already been used with promising results for forecasting the changes of the next day or two; but until the potentialities of the newer processes are thoroughly explored, the forecaster will still need to analyse his own charts. Now this in itself is a complex task. It demands a long training in constructing a three-dimensional picture of the atmosphere from separate charts of horizontal and vertical sections, and also in accounting for the changes from one set of observations to the next.

But although analysis is an essential stage in the preparation of any forecast, the writing of the first text devoted wholly to the subject has been left to Prof. W. J. Saucier, associate professor at the Agricultural and Mechanical College of Texas, and formerly instructor in meteorology in the University of Chicago. In every respect Prof. Saucier has produced an excellent book—clear and comprehensive, with enough diagrams and physical explanations to make the reading easy, and with the right amount of mathematics for rigorous stiffening. The first third is concerned with the necessary tools and techniques —the atmospheric variables and their physical relationships, stability, the characteristics of the various kinds of chart and diagram, and the theory and practice of scalar analysis. In the main business of the text, the author discusses analysis of surface charts and isobaric and isentropic charts for higher levels, vertical cross-sections of the atmosphere and the kinematics of airflow; the chapters on each of these sections should make rewarding reading for the experienced forecaster as well as for the trainee, and will take him over a wide range of up-to-date thought on the functioning of the atmosphere from the forecaster's point of view. As befits their nature and their place in a book of this scope, large-scale and local features and charts for tropical regions are treated more sketchily (forty pages in all) in the last three chapters.

The text is well documented both by footnotes on each double-columned page for particular references, and at the end of each chapter for more general reading. Throughout the work the author has succeeded in combining a sound treatment of the physical processes with his account of the empirical principles of analysis, and he has striven to treat the atmosphere as a single system the parts of which interlock through great depths and over wide areas even though the mechanism is not yet fully understood. J. M. Stagg

Atlas du Ciel

Par Vincent de Callatay. Pp. 151+11 photographies. (Bruxelles: Les Éditions de Visscher, 1955.) 450 Belg. fr.

THIS is a star atlas for amateurs. The author certainly succeeds in catching the eye by a series of maps of considerable beauty in which the stars appear white and the sky black. The maps are not obscured by printing further information on to them; instead, the constellation names and boundaries, star names, co-ordinates and further information are added by means of subsidiary maps and tables.

There are nine maps depicting a full hemisphere from various aspects, and in these there is no differentiation of the magnitudes of the stars shown. Then follows the main series of twenty-seven rectangular maps each covering a region of about 70° × 50°. For these the magnitudes (down to the fifth) are differentiated, but not very clearly. Those maps referring to the northern and equatorial regions of the sky have north at top, while the southern maps have south at top. Running through the book is a useful description (in French) of the various types of object in the sky and of other astronomical matters, but this text matter is not particularly connected with its nearby map. At the end there are twelve fine photographs chosen from the Mount Wilson–Palomar list of celestial objects.

The arrangement is not a very convenient one for those who wish to use the book as a working star atlas. It is somewhat difficult to locate the appropriate map, and then it is necessary to look elsewhere (sometimes over the page) to interpret it. Some minor inconsistencies and inaccuracies can be detected.

C. W. Allen

Semi-Micro Organic Preparations

By Dr. J. H. Wilkinson. Pp. x+94. (Edinburgh and London: Oliver and Boyd, Ltd., 1954.) 8*s.* 6*d.* net.

DR. J. H. WILKINSON joins the growing band of chemists who have published their methods of preparing organic compounds on the so-called 'semi-micro' scale. Since one of his recipes requires 50 c.c. of one reagent and 4·5 c.c. of another, 'small-scale', which many favour, would seem to be the better term.

In an opening section of eleven pages, the author describes his techniques, which include not only customary small-scale types but also pieces of apparatus of his own design. In the remaining pages he gives clear instructions for a variety of preparations ranging from the simple esterification to catalytic hydrogenation, and to the more elaborate exercise requiring the use of a reagent such as aluminium *iso*propoxide. He blends with his instructions valuable comments on the reaction in question and directs attention to significant points of theory.

The experiments do not run in a sequence and do not cover any particular syllabus, the intention being to show what can be done on the small scale. As with other enthusiasts, Dr. Wilkinson occasionally overworks an innovation. Thus he uses a special apparatus for the preparation of tribromaniline, when surely a drop of each reagent brought together on a watch-glass would suffice. Nevertheless, this is a helpful book for those desirous of becoming acquainted with these economical and time-saving methods.

G. Fowles

The Science Masters' Book

Series 3, Part 2: Chemistry. Arranged and edited by G. Fowles, with the assistance of E. H. Coulson and Charles Holt. (Experiments selected from Nos. 68–128 of *The School Science Review.*) Pp. xi+286. (London: John Murray (Publishers), Ltd., 1955. Published for The Science Masters' Association.) 17*s.* 6*d.* net.

THIS book contains selected experiments, apparatus and teaching devices from the *School Science Review* of the past eighteen years, divided into six parts which vary by design from the very elementary to the more advanced work of a sixth form. Throughout the book the lesson of what improvisation has meant to the schoolmaster is plain to see, and, if for this reason only, the book should be stimulating for teachers of any experience.

Of course, the selection is bound to meet with criticism; but it is a little difficult to understand why in some cases more pruning was not carried out, so leaving space for other experiments—three ways of showing the action of steam on magnesium are given, when the last and simplest would have sufficed. In all cases the essential details are given, and the diagrams are very clear; but here again some of the latter might well have been omitted without loss of clarity. As more than a hundred authors have contributed to this book, it is only to be expected that the standard of clear and concise English has not always been maintained; but the use of the word 'treat', the first person, and some asides are to be deplored.

A new departure is the introduction of theoretical comments and a list of references, and this is most pleasing and helpful. The later sections are very well done, particularly those on electrochemistry and small-scale work. The book as a whole should be a welcome addition to any science teacher's bookshelf.

J. C. Stredder

University Physics

By Francis Weston Sears and Mark W. Zemansky. Second edition, with Supplementary Problems. Pp. viii+1031. (Cambridge, Mass.: Addison-Wesley Publishing Company, Inc., 1955.) 10 dollars.

THIS book covers the whole of physics up to approximately ordinary-degree standard. It is lavishly illustrated with well-thought-out diagrams, 'multiflash' photographs of moving bodies in dealing with mechanics and sound, and one two-colour diagram. It should be very useful to the students to whom it is addressed. It is doubtful, however, whether it would fit in with the British university system; it is too elementary as an introduction for students who have passed Advanced Level physics at school and, in spite of its size (and weight), it does not include all that is usually dealt with in an ordinary-degree course. Rigidity and the twisting of rods, for example, are not included, nor the relationship between the elastic moduli.

The rationalized M.K.S. system of units is used for dealing with magnetism and electricity. Despite its obvious practical advantages, the reviewer thinks that it is not a suitable system for introducing the subject to elementary students, with its arbitrary introduction of the factor 4π, and the premature disclosure of the role of the velocity of light.

On the whole, however, the book contains many novel and interesting ways of presenting the various branches of physics, and university teachers in Britain may well profit by its study.

MINING RESEARCH ESTABLISHMENT, ISLEWORTH, OF THE NATIONAL COAL BOARD

By Dr. L. C. TYTE, C.B.E.
Director

THE Mining Research Establishment was founded by the National Coal Board in July 1952 within the Scientific Department under the director-general, Dr. Idris Jones. It is the first research unit of any size to be assembled in Britain for the study of mining problems other than those directly related to safety. The purpose of the Establishment is to carry out research aimed at increasing the efficiency of coal production, in which health and safety considerations are implicit, and it works in very close touch with the Board's Central Engineering Establishment at Bretby, which is responsible for engineering development.

The site selected for the Establishment was the former British Lion Film Studios at Isleworth, Middlesex; it covers an area of some six and a half acres and is situated in pleasant surroundings in the London area. Reconstruction of the existing buildings has been in hand over the past four years, and the present scheme will be completed before the end of the year. This will provide extensive modern laboratories, working spaces for large-scale technical experiments and adequate workshop and other ancillary services.

The initial plan was for an Establishment with a staff of 350, of whom 230 would be scientists and scientific technical officers, and having an annual revenue expenditure of about £300,000. Unfortunately, through the national shortage of scientists and technologists, this size has not yet been attained. Although the investigations are primarily of a physical and mechanical engineering nature, the range and complex nature of the work are such that it is usually advantageous to employ teams of staff trained in different disciplines. Thus, in addition to physicists and mechanical engineers, mining and electrical engineers, metallurgists, mathematicians, geologists and chemists are all making valuable contributions to the solution of the urgent national problems of coal mining.

Coal Winning

The most important task assigned to the Establishment is research into methods of improving techniques of coal winning, with prime emphasis on mechanization. This objective provides an interesting example of the constant interplay there must be in this work between laboratory experiments and underground field trials. Machines for winning coal from the seam employ cutting tools ranging from small, rapidly moving picks to large, massive, slowly moving wedges which may be applied continuously or impulsively. The machines are required to operate in a wide variety of conditions depending on the mechanical properties of the coal substance, the thickness, gradient and other geological features of the seam, and the nature of the roof and floor rocks and the forces and constraints which they impose on the seam. It will be appreciated that mechanical breaking down of the coal from the seam is not enough, but that mechanical means of loading the won coal on to the face conveyor system is an essential to increased mechanized productivity and is a feature of modern cutter-loader machines.

One of the lines of attack followed in the laboratory has been the examination of the mechanical properties of coal, including measurement of the elastic constants and a study of coal breakage. This work is complicated by the fact that, as a bedded material, coal behaves differently to forces normal and parallel to the bedding planes. Moreover, it is intersected by planes of weakness normal to the bedding planes which on the larger scale are known as cleats. Coal is also, petrographically, a very mixed substance. Hence, in order to restrict the total number of variables while still retaining a representative cross-section, nine coals have been selected for all experimental work. In spite of these difficulties, progress is being made in building up an understanding of coal breakage.

In parallel with these experiments, measurements are being made on the forces required to pull tools through blocks of coal and the influence of such factors as depth of cut, blade angle, direction of cleat to the direction of cut, the coal used, size of product, etc., on the peak and mean forces required. From earlier experiments of this kind, it was observed that the force required to draw a tool through hard coal was not uniform but rose to peak values at places of high resistance, afterwards dropping to low values when fracture of the coal had occurred at these points. This observation led to the idea of applying percussion to a plough blade, which would only be called into operation when the blade encountered locations of high resistance increasing the tension on the haulage chain. This had the advantage of reducing the peak loads on the haulage chain, thereby improving the stability of the plough, and gave promise of a machine capable of cutting coals too hard for attack by conventional static-bladed ploughs and of working in thin seams, for which there is currently an urgent need. Experimental models of such an 'auto-percussive' plough have been made and used underground, and this work is being prosecuted vigorously.

Coal is, of course, also won by blasting it from the solid, or undercut seams. As a means of improving safety in the use of explosives and of reducing the dust hazard mentioned below, the idea of blasting coal by explosive charges placed in holes already filled with water under pressure has been advanced and is in use experimentally in certain pits. Research is in hand to examine in detail the basic factors entering into this technique.

Strata Control

Almost all mechanized cutter-loaders requir 'prop-free' fronts; that is, coal faces without prop more or less up to the coal face but with the roo supported in this region by cantilever roof bars Increased output calls for increased rates of advanc of mechanized faces, and the trend will be to roo support systems advanced mechanically, and ulti mately automatically, rather than by manual resetting of props. To extend these techniques with safety, much more knowledge is required of the conditions they have to meet. Hence the first objective of the research on strata control has been to devise experimental methods for measuring underground the loads which props are called upon to withstand and the convergence and lateral movement between roof and floor.

The problems so far discussed are only concerned with the immediate protection of men working in the coal face; there is also the important problem of ultimate support of the overlying strata in the waste area which controls surface subsidence and the workability of other adjacent coal seams. Again, there is a wide field for pressure measurements both in packs built in the waste and also in the virgin rock before the coal has been extracted.

These measurements, important though they are, are only the first steps to obtaining an understanding of the stresses and movements in the strata induced by the operations of mining.

Driving of Tunnels

While much of British practice follows the procedure of making roadways in the coal seam, it is an essential feature of opening up new districts and developing new mines that tunnels and drifts should be driven through rock. The speed with which this can be done is of importance since, by this means, new coal resources can be made more quickly available for production and the capital cost of new workings reduced. Much can be done in this direction by studies of organization and management. This, however, is outside the scope of the Establishment, and is being carried out by the National Coal Board's Production Department; research is being devoted to the actual mining processes. Rock drilling is an important aspect of tunnelling and extensive investigations are being made. One of these is concerned with the incidence of 'clogging' with rotary-drill tools by the debris created in making the hole. Conventional twist-drill bits, both with streamlined and non-streamlined bit-rod connexions, Continental-type bits and hollow-type bits deriving from earlier work in the Establishment, have been compared.

The new technique of percussive-rotary drilling has been examined in a preliminary way, and the results indicate such promise that the work will be extended to find the most suitable combination of variables for coal-measure rocks.

In parallel with the experiments on drill design discussed above, a study has been made of the metallurgy of hard tool tips for drills. The relative parts played by abrasive wear and by chipping have been established, and although much work remains to enable the optimum cobalt content and grain size to be established for any particular purpose, it has been possible to draft a provisional specification for tungsten carbide drill-tip materials. Similar questions arise in determining the proper material to use for coal-cutting tools; but this is only one class of the many metallurgical problems arising in the ndustry, which is one of the biggest users of steel n Britain.

Underground Conveyance of Coal

When coal has been won at the coal face, it has then to be transported to the pit shaft. One of the steps in mechanization of pits during the past fifty years has been the introduction of belt conveyors for this purpose, and now more than 90 per cent of the coal raised is moved in some part of its journey to the pit bottom by conveyor. The Creswell Colliery disaster of 1950 directed attention to the fire hazard of rubber conveyor belting, and, following research, P.V.C. (polyvinyl chloride) belting is now obligatory for all new purchases of belting. However, although the introduction of P.V.C. has eliminated the inflammability of belting as an underground hazard, it does not mean that the perfect belt has been produced. Investigations are in hand to determine the optimum design and materials for the belt to have a long life of efficient service. Such factors as flexibility, distribution of load between the various plies and frictional properties of the surface are being examined; but for use in some situations in the pit, it would appear that random damage such as holing or edge tear are the most important factors to be considered.

Environmental Conditions

A consequence of working or disturbing coal and the surrounding rock strata is the emission of methane. This is well known to offer a serious explosion hazard. Research at Isleworth in this field is directed to improved instruments, both portable and fixed, for providing both an alarm or cut-out system when the percentage of methane in the mine air exceeds a prescribed level and also to give a continuous monitor record of the methane content. In addition, instruments are being devised to measure high methane concentrations required in connexion with methane-drainage schemes.

When coal or rock is broken, it is inevitable that some fine dust is formed. If this becomes airborne, the respirable portion (that is, less than 5 microns in size) presents a serious health hazard as the cause of pulmonary diseases. This has long been a matter of serious concern to the National Coal Board, which has devoted a great deal of effort to combat the scourge of pneumoconiosis. The part played by the Establishment is in dust assessment and study of means of suppressing it. The conception of the elutriator to eliminate the collection of dust larger than the size range required has simplified the counting of slides to determine dust concentrations, while the recent development of the 'long-running thermal precipitator', which will record the mean airborne dust concentration over a working shift, will do much to assist the determination of dustiness of working conditions. The problem of suppression of airborne dust has proved far less tractable. Experiments and theoretical considerations have shown that gravity water sprays are valueless for removing airborne dust in the respirable range from mine air, although, of course, this does not mean that water sprays may not be useful for consolidating dust before the coal reaches transfer points and hence reducing the amount of dust made airborne. However, studies in dust suppression by water and wetting-agent solutions have suggested that the particular coal concerned plays an important part in the effectiveness of such measures, and the problem is receiving further close attention. The difficulties of dust suppression underline the fact that the real solution is to minimize the dust produced rather than to attempt to deal with it once it has been made, and hence studies have been made on the production of dust by different methods of coal breakage and by technical methods of working such as drilling.

It is opportune to remark that fine dust coarser than the respirable faction is also a hazard in mining, since a cloud of such coal dust can participate in an explosion initiated by a methane gas explosion, augmenting the force of this latter explosion to a very marked degree. Work on this, as on all explosion problems, is done by the Safety in Mines Research Establishment and not by the Mining Research Establishment. Close touch and interchange of views is maintained between the two Establishments.

Although most British pits are fairly dry, the use of water for dust suppression increases the relative humidity of hot workings. The combined effect of high temperature and high relative humidity has a deleterious effect on the physical and mental working capacity of men. At the moment, this problem arises principally in headings, but future exploitation of deeper coal measures will make the problem more acute. A preliminary study is being made of the sources of heat to underground workings, of which one of the chief is heat flow from the virgin strata surrounding the opening, and of means of ameliorating working conditions.

Ventilation plays an important part in controlling the environmental conditions from whichever of the three sources discussed above the noxious effects arise. Again, the prime problem from the research angle is the precise measurement of the quantities concerned, such as air pressure, mass flow, temperature and humidity of the air stream.

Instrumentation

A recurrent need in all fields of mining is for more measurements and for instruments with which to make them. Due to the explosion hazard, all instruments must either be intrinsically safe or housed in a flameproof box. Instruments existing commercially to make the measurements required by the current research programme with the necessary degree of accuracy are virtually non-existent. Hence a considerable portion of the effort of the Establishment is devoted to devising and designing pitworthy instruments which will do their job safely under exacting conditions. There are advantages in using transistors as a substitute for valves, and a number of instruments are in the course of development which employ these devices.

Not merely are measurements required for the study of environmental conditions and the behaviour of strata but also to give a precise picture of the performance of a coal-winning machine underground. This is an entirely new field, and instruments are at present being devised and constructed to give comprehensive information on the forces encountered by, and the performance of, the 'auto-percussive' plough when working in a seam. This technique should give most valuable information for the design of new and improved machines of all sorts. The need for adequate instrumentation in environmental studies has already been mentioned; but it should be emphasized that this phase is only the provision of the tools to attack the main problems in those fields which are concerned with the improvement of underground working conditions.

Mining is a traditional industry in Britain and, as such, is one on which it is difficult for research to make an immediate impact. However, it is bristling with complex problems requiring urgent solution, and it is therefore a stimulating challenge to scientists and engineers. No doubt, in many cases, careful work will merely establish that current practice, resulting from an intuitive approach and long experience, is in fact soundly based. But the coal-mining industry must advance and is in fact advancing in its technique at an ever-increasing pace; and here scientific research will make its fullest contribution and reap its reward by helping the advance of national prosperity.

THE PLACE OF SCIENCE AND THE HUMANITIES IN EDUCATION

A DEBATE on the motion "That Science can provide as Good an Education as the Humanities" was organized by the Fine Chemicals Group of the Society of Chemical Industry, and was held in the Senate House of the University of London at 7 p.m. on April 20. Sir William Ogg was chairman of the debate, which was attended by some five hundred people. Speakers for the motion were the rector of the Imperial College of Science and Technology, London, Dr. R. P. Linstead, and Prof. A. R. Ubbelohde, also of that College. Speakers against the motion were the vice-chancellor of the University of Nottingham, Mr. B. L. Hallward, and the headmaster of Winchester College, Mr. H. D. P. Lee. After these speeches, brief contributions from members of the audience were made at the invitation of the chairman.

In the course of the debate, it was evident that there was some shift of targets, according to whether the speakers on either side were thinking of education chiefly at the school-level, or whether higher education was included and even specifically aimed at.

With regard to public school and secondary education, Mr. Hallward said that to include an even greater proportion of scientific subjects than heretofore, so as to produce more young technicians trained in science on something like the reputed Russian plan, could have grave objections with regard to their other opportunities and duties in adult life. Mr. Lee stressed the practical difficulties from the point of view of an already crowded school timetable. When essential school subjects such as English language and literature, geography and history have been provided for, and highly desirable subjects such as at least one foreign language and mathematics have been included, the distributable periods for more science or for other subjects are in practice quite limited. Furthermore, not much physics can be usefully taught at school before sufficient mathematics has been mastered.

These considerations were not really in conflict with Dr. Linstead's practical formula that everyone should acquire a very good knowledge of their own language and of mathematics, at least one foreign language (preferably living), general science and history and geography—chronology and the globe in Locke's words. Subsequent specialization in the arts or the sciences may occupy, say, two years at school and three at the university; but premature specialization is deplorable both for scientists and for non-scientists.

Prof. Ubbelohde said that though all would agree about the strength and grace contributed to the spirit of man by the new learning of the Renaissance, certain grave sources of weakness arise from the more mechanical practices of humanistic school teaching. Instead of giving real access to Greek and Roman civilization, all too often there is a prolonged and clumsy fumbling with rules of grammar and composition, and the mechanics of constructing Greek and Latin verses. Instead of teaching living foreign languages, schools often teach lists of words, irregular verbs and grammatical rules. Instead of teaching history as a living perspective of human thought and action, schools often concentrate on kings and queens and concubines and sometimes on archbishops and heretics.

Each of the speakers also dealt with broader philosophical aspects of education in science and in the humanities, and with higher education at the universities. Dr. Linstead quoted the "fanaticism of veracity" for which scientists were praised by Huxley; though this is only partly compensated for by the greater appreciation of beauty which may be attributed to humanists, the main influences which affect the moral and social education of a man come from outside his formal instruction and are essentially ndependent of the choice of his main subjects of study. A university student specializing in science, particularly for an honours degree, has to work very hard to master a large amount of factual material, and to complete the practical courses required. Particularly in the early years of a scientist at a university, these heavy demands on time leave far ess opportunities for general reading, for games and even for gossip. At first, science students appear to become more narrow, more specialized and even rather duller than their humanistic contemporaries; but at the postgraduate stage, after this novitiate in science, a great breadth of interests is discernible; comparisons at this level are by no means unfavourable to a scientific university education. In the research laboratory, both the critical faculties and creative power of students receive their maximum encouragement. This stimulation of the restless spirit of inquiry, and its real satisfaction by research, is an unforgettable educational experience. A positive advantage is the large element of practical work involving skilled use of the hands, which is an undoubted source of satisfaction to so many scientists.

Mr. Hallward and also Mr. Lee stressed the large gaps in an education specializing in pure science. Chief of these is that the sciences do not give access o judgments of value. In particular, science is amoral. It may provide just that knowledge which is required for automation, but science fails to give an understanding of human motives which are equally important for automation—for example, in dealing with trade union problems.

To focus this part of the debate, Mr. Hallward gave a list of some of the most compelling problems of our age, in order to point out that an education based exclusively on science could make the best ontribution to their solution in only very few instances. These were: (*a*) the spiritual and moral risis of Western civilization; (*b*) the conflict between Christianity and materialism; (*c*) international tension; (*d*) the growth of the power of the State and the tendency to sacrifice liberty for equality; (*e*) the evil power of certain dictators or oligarchs over men's minds, with the possibilities of 'brain washing'; (*f*) industrial strife, with special reference to current policies of 'beggar my neighbour' and certain aspects of trade union politics; (*g*) world population and food supplies; (*h*) education for leisure, shortening of the working day, the development of automation; (*i*) the triumph of ugliness and Philistinism.

Those opposing conceded that science trains the quantitative measuring faculty in the broadest sense. It develops human capacities for observation and experimentation, especially in the quantitative fields of experience. Popular use of the word 'scientific' to mean 'rationally argued' is, however, very superficial. Even where science can provide or suggest solutions to current problems, scientific training does not develop the faculty of arguing about opinions, or of persuading human behaviour. Both the emotions and the artistic sense are highly important for sound living, and are left wholly uneducated by science.

Prof. Ubbelohde stressed that an excessive preoccupation with specialized knowledge in either the arts or the sciences will fail to develop social faculties in a man or woman. But science has a real social contribution to make in the sense that even the humblest learner begins to understand by the earliest steps of his progress that he belongs to a house of many mansions, built by the labours of many workers and honouring named heroes from all over the world. Science gives one of the most direct entries to important activities that transcend national differences. So far from sensing barriers between the learning of various nations, scientists are keenly and indeed desperately aware of the interdependence of the peoples of mankind. To form a part, however humble, in an international advance upon ignorance and human helplessness is a social privilege which belongs naturally to scientists.

A second important educational fact about science is that many people find natural phenomena highly interesting. For example, Sir Walter Raleigh, Charles II and Dr. Johnson had all found solace from other troubles in a concentration on practical chemistry. Education to be effective must harness and guide real, substantial and perennial interest. Furthermore, since interest in natural phenomena can be developed and cultivated at various levels, scientific education tends to cement together rather than to separate various classes in the community.

A unique contribution to education made by science is in its approach to knowledge by experiment. This highly distinctive practice is quite modern. To utilize the full educational force of science, it is not sufficient to teach abstract sciences of the mind, such as mathematics. The mind must grow by learning to humble itself before objective facts of observation. By degrees it must learn to submit even the most forceful and imposing mental constructions to external tests. Almost in spite of itself the intellect learns that much human knowledge incorporates progressive experience. Knowledge inherited from precursors is important, but training particularly in the experimental sciences cannot induce complacency with inherited knowledge. Notwithstanding our shrunken world, the vast realm of knowledge remains wide open to scientific exploration. This maintains a freshness of outlook in scientific education; as is only natural, for humanistic learning the educational enthusiasm which was at its flood at the time of the Renaissance has by now undergone considerable attrition.

Each of the speakers, whether for or against the motion, made it clear that no support should be given to a humanistic education without access to science and the experimental method, or to an education that was wholly scientific without access to a training in values. Even from the strictly vocational point of view, the technological climate we now live in makes demands on education that are not fully met by past practice. Power on a very extensive scale has been placed in human hands during the past fifty years—as always in things human, power and knowledge for good or for evil.

We simply cannot allow anyone with any vocation of leadership or of effective service to remain wholly ignorant of science. In order to judge and to direct important policies, perspectives of action need to be viewed rightly; this includes judgments of potential contributions from science and technology. It is equally foolish to attribute our current malaise wholly to the ignorance of humanists at odds with forces they do not understand, or wholly to the rashness of uneducated scientists acting under the impulse of monstrous powers they should never have released. A new educational synthesis between humanism and science seems called for.

In this connexion, an important observation was made by one of the audience, Mr. J. A. Ratcliffe. The current forms taken by science teaching at schools and still more at the universities are determined by a strong vocational demand. By the time scientists or engineers or medical men or many othe university graduates leave the university, they ar expected to have acquired effective training in thei speciality. Teaching courses in science contain i themselves many of the benefits claimed for scientific education; but their need to provid effective specialized training makes it necessary t include features not in themselves of high educationa value.

A similar comment can probably be made abou specialized courses in humanistic subjects when thes aim at giving effective specialized training. It ca likewise be argued that the influence of the Renaissance grammarians still unduly affects education i classical subjects at school; unconsciously this i still organized to give a training which was of grea importance for those who needed accurate professional use of Greek and Latin. By thinking ou afresh the content of a course in general science a the university-level, including access to the experimental method, it should prove possible to mak even fuller use of the educational possibilities o science and to promote a new 'Greats' course combining humanities and sciences effectively.

With all this new 'tailoring', it is not yet clea whether the specialists in either camp will be able t impart the vital academic experience of study i depth of selected subjects to students of new hybri courses. The debaters did not enlarge on such doubts but were content to agree that appropriate access t the humanities and to the sciences is a necessar part of good education at the present time.

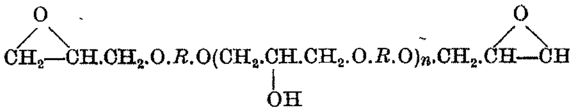
A. R. Ubbelohde

EPOXIDE RESINS

Under the title "Epoxide Resins, their Chemistry and Structure in Relation to their Properties and Applications", the Plastics and Polymer Group of the Society of Chemical Industry organized a symposium during April 11–13, which was held in the Beveridge Hall of the Senate House, University of London. About four hundred scientists registered for the conference, including forty overseas representatives of the United States, the Netherlands, Switzerland, Germany, Italy, Belgium, France and Sweden. Preprints of most of the papers presented were available before the meeting, so that authors needed only to summarize their contributions, with the result that ample time was available for discussion. Dr. S. H. Bell, chairman of the Group, acted as general symposium chairman; Dr. J. J. P. Staudinger, the late Dr. S. Whitehead and Dr. N. J. L. Megson took charge of the individual sessions, which were all well attended.

The considerable interest aroused by such a specialized subject as epoxide resins is to be attributed to the comparative newness of the materials, which have been commercially available for only a few years, combined with the outstanding properties of the products and a lack of detailed knowledge of their chemistry. They already hold a firm position as excellent adhesives, and they show great promise in the glass laminating field and for the potting and encapsulating of electronic equipment. Furthermore, as some of the papers showed, they are capable of extensive modification to yield products of potential value in other applications.

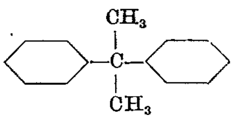
The reaction of epichlorhydrin with a phenol t give an epoxide derivative has been known for abou a hundred years, but the exploitation of the metho in the production of a polymer is a recent invention Epoxide resins were developed simultaneously b Ciba in Switzerland and by Davoe and Raynolds i the United States, and were first made on an industrial scale in 1950. The essential step is the reactio of epichlorhydrin with a bifunctional phenol, of whic diphenylolpropane (2 : 2-*bis*(4-hydroxyphenol) propane) is the commonest example. The type o molecule obtained can be represented by formula I



$$\overset{O}{CH_2\text{—}CH}.CH_2.O.R.O(CH_2.\underset{OH}{CH}.CH_2.O.R.O)_n.CH_2.\overset{O}{CH\text{—}CH}$$

(I)

where R is



The value of n will depend on such factors as rati of reactants and time of condensation. If n is unit or greater, then the characteristic structure is tha of an aliphatic aromatic polyether containing termin epoxy groups and pendent hydroxyl groups. Th molecule can be cured or hardened by the additio of dibasic acid anhydrides, such as phthalic anhydrid or of aromatic or aliphatic polyamines or relate compounds. The curing conditions and properties of the final resins will depend on the molecular weight of the original uncured resin and on the type of curing agent used.

As pointed out by Mr. E. S. Paice, commercial production depends on the large-scale availability of epichlorhydrin. This compound is now made as an ntermediate in the synthesis of glycerin through the hot chlorination of propylene, and production is ikely to be undertaken in Europe later this year.

The fourteen papers of the symposium, although very varied in character, can conveniently be grouped into four main categories: chemical aspects, including hardeners (five papers); modified resins (three papers); applications (two papers); and special aspects (four papers).

Chemical Aspects

Difficulties associated with hardeners were disussed by F. J. Allen and W. M. Hunter, with special reference to resins containing no free hydroxyl groups formula I, $n=0$). Hardeners such as phenolic resins may react in three ways, all of which lead to the ormation of a potentially reactive hydroxyl group. Epoxide/phenolic resin mixtures are stable for coniderable periods, and as a result are useful for making laminates, since impregnated sheets can be tored safely for several weeks. Acid anhydride hardeners are frequently used, but suffer from the defect that they are insoluble in the epoxide resin at room temperatures, so that mixing and curing have o be carried out at high temperatures and for xtended times.

Aliphatic and aromatic amines are more favoured because they can induce hardening at low temperaures. Furthermore, if polyfunctional amines are used, they can cause ready cross-linking. They may act catalytically, causing polymerization through poxide groups, or they may function by reacting with the resin. Tertiary amines or monofunctional secondary amines are typical of catalytic hardeners, which bring about ionization of epoxide groups.

Typical polyfunctional aliphatic amines are diethylnetriamine and triethylenetetramine. The disadvantages of such amines include development of a igh exotherm during hardening, whereby bubbling s caused in the resin; toxic properties; short pot-ife of resins made with them; and critical nature of esin/amine ratio. Some of these drawbacks can be vercome by using adducts or reaction products of the amines with other compounds, including the resin tself, acrylonitrile and ethylene (or propylene) oxide. uch adducts increase pot-life and reduce exotherms ut tend to bring about some deterioration in proerties of the cured resin. For general use, aromatic mines such as *m*-phenylenediamine and 4 : 4′-iaminodiphenylmethane are satisfactory, leading to igh heat-distortion temperatures and good mechancal properties.

Dr. W. Fisch, with Dr. W. Hofmann and Dr. J. Koskikallio, described chemical investigations on the ardening of resins (formula I, $n=1$ or more) with hthalic anhydride. Previous work had shown that the anhydride reacted with pendent hydroxyl groups o yield monoesters, and that the carboxyl group thus formed reacted with an epoxy group to give a diester and a further hydroxyl group, which could tself react with anhydride. Analytical studies of the reaction revealed the surprising fact that epoxy roups decreased much more rapidly than the diesters increased, and it therefore appeared that epoxy groups must take part in other reactions, for example, with hydroxyl groups. It was further found, surprisingly, that the reaction of anhydride with hydroxyl groups leads to an equilibrium which is strongly dependent upon temperature. Fisch concluded that a cured resin contains anhydride, monester and hydroxyl groups even after complete reaction of the epoxide groups.

Novel types of curing agent, namely, aniline-formaldehyde resins of low molecular weight, were described by Dr. R. E. Bishop. Such resins may be considered as closely related to aromatic amines of more conventional types, and in fact they yield cured resins having properties similar to those obtained by the use of 4 : 4′-diaminodiphenylmethane. The resins have advantages in being relatively cheap and in not possessing bad dermatitic properties.

The use of infra-red spectroscopy as a tool in following the curing of resins formed part of the subject of a paper by Dr. L. A. O'Neill and C. P. Cole. The results suggest that hardening of a resin with ethylene diamine proceeds through interaction of epoxy and primary amine groups, followed by reaction of an epoxy group with the secondary amine thereby formed. When highly complex polyamides are used as curing agents, cross-linking occurs at an earlier stage of reaction, although the resins are then somewhat softer. From chemical studies, O'Neill and Cole conclude that the esterification of epoxide resins with long-chain fatty acids (for example, from linseed oil) consists of a rapid attack of epoxy groups followed by a somewhat slower reaction with hydroxyl groups.

This last finding was confirmed by Dr. P. Bruin, who pointed out that since esterification by long-chain fatty acids uses up most of the epoxy groups, final curing has to proceed without making use of these groups. Dr. Bruin also discussed the mechanism of hardening with amines, as well as the potential use of phenolic resins (see Allen and Hunter, above). He pointed out that it is essential to strike a proper balance to prevent interaction of methylol groups in such resins, before the phenolic hydroxyl groups can react with the epoxide resin.

Modified Resins

The so-called 'polyepoxide' resins were described by Miss M. G. Ivinson, B. R. Howe and F. M. Karpfen. These materials are essentially phenolic resins in which the hydroxyl groups have been combined with epoxy residues. They yield a rigidly cross-linked system and, compared with normal epoxide resins, cure much more rapidly with primary amines.

A different type of modification can be made by making polyamides, derived from dimeric fatty acids. react with epoxide resins. A paper by D. E. Floyd, D. E. Peerman and Dr. H. Wittcoff devoted much attention to the mechanism of dimerization, it being uncertain whether the reaction is of Diels–Alder type or whether it occurs through Farmer's suggested conjugated free radical. The resins themselves are recommended by Wittcoff for surface coatings, adhesives, castings, tools and dies, potting and encapsulation, and for reinforced laminates; the outstanding properties are claimed to be low shrinkage, low exotherm, low volatility and low toxicity, combined with excellent adhesive and 'wetting' properties, and good dielectric strength.

Dr. T. F. Mika discussed the use of rubber-modified epoxide resins. Nitrile rubbers containing sulphur react through thiol groups, whereby mixed polymers are formed. The epoxide resin constituent acts as a reinforcing agent and confers improved solvent resistance and increased tear-strengths.

Applications

Mr. H. G. Manfield gave a comprehensive account of the use of epoxide resins in the potting and encapsulation of electronic equipment. The resins have special value in that they have good sealing properties. Manfield considers that their greatest future outlet lies in transformers, but pointed out various difficulties in this field. Supported by Dr. A. J. Warner, he made a plea for closer liaison between users and resin manufacturers, particularly from the point of view of electrical properties over a range of frequencies and temperatures.

The possible use of epoxide resins as stabilizers for polyvinyl chloride (P.V.C.) was discussed by Dr. E. C. A. Horner. When used with other compounds, not necessarily good stabilizers themselves, a synergistic effect is observed, whereby the resulting stabilization is better than that expected from either component separately.

Special Aspects

A paper by Dr. L. B. Bourne, a medical officer attached to a large organization, raised much interest since it dealt with handling precautions. Dr. Bourne stressed the toxic nature of many of the curing agents employed, and the necessity for extreme care in large-scale use. He considered, however, that the use of good barrier creams to reduce skin contact, efficient ventilation and the reduction to a minimum of quantities handled at any one time, combined with good training of personnel and the use of cautionary notices, could be adequate. He gave details o desirable treatments in case of need.

The important role of glass fibres as reinforcing agents was covered by Mr. K. J. Brookfield, who outlined the methods of production of fibres and described the special treatments now provided to improve adhesion of resins. These treatments include the use of methacrylato chromic chloride vinyl trichlorosilane and a new compound based on the interaction of allyl trichlorosilane with resorcinol.

The fundamentals of adhesion, with special reference to epoxide resins, were most lucidly presented by Dr. N. A. de Bruyne. Experiments on monomolecular films, determination of dipole moments and influence of chemical structure all lead to the conclusion that hydroxyl groups are largely, but not entirely, responsible for the good adhesive properties Measurements of differential strains in aluminium joints similarly suggest that the rise in breaking stress with hydroxyl content is associated with a fall in the residual stress.

The place of epoxide resins in industry was discussed by Mr. E. S. Paice in the final paper. Basing his conclusions on estimates in the United States he thought that, by 1960–62, the market in Great Britain should be between 7,000 and 10,000 tons a year. Of this amount, 55 per cent would be absorbed in surface coatings, and the remainder would go to 'potting' of electrical equipment, press tools, structural laminates, adhesives and miscellaneous uses Although increase in production would naturally lead to a reduction in price, he considered that epoxide resins would remain inherently more expensive than existing resins; nevertheless, he believed their special properties would ensure them a prominent place in industry.

N. J. L. MEGSON

OBITUARY

Mme. Irène Joliot-Curie

ALTHOUGH the health of Madame Irène Joliot-Curie had given cause for anxiety for several years, her death on March 17 came as an unexpected shock to those outside her immediate circle, not only to those who had known her personally but also to all who have worked or studied in the field of radioactivity. She was born in the stirring days of radioactivity when her parents were making their great discoveries, she grew up with radioactivity, and all her working life was devoted to its study. She bore an honoured name, to which she added lustre by many contributions of great importance in radioactivity and in the development of nuclear physics.

Irène Curie was born on September 12, 1897, the first child of Pierre and Marie Curie, *née* Sklodowska, a few months before the publication of the papers announcing the discovery of polonium and of radium. Her early training was interrupted by the First World War; during part of which she served as a radiographer, and afterwards she became 'préparateur' to her mother at the Laboratoire Curie of the Institut du Radium in Paris. Here she received a thorough grounding in all aspects of radioactivity, both physical and chemical, which gave a secure basis for her future work. Her first important paper was on the α-rays of polonium, presented for her doctor's thesis in 1925. In 1926 she married Frédéric Joliot, who had joined the Institut du Radium a year or two earlier as special assistant to Mme. Curie, and there began a collaboration of husband and wife in scientific work rivalling in productive genius even that of her parents. Equal in the partnership, each was a fitting complement to the other, and together they published some remarkable work. The most outstanding of their joint papers were published in the years 1932–34. In the first of these, on the radiation excited in beryllium by α-particles, they reported a very strange effect which provided the clue to the discovery of the neutron. Then, after studying the conditions of excitation of neutrons by the impact of α-particles on various elements, they turned for a time to the 'materialization' of positive electrons through the action of γ-rays of high energy This was followed by a systematic study of the radiations emitted from the lighter chemical elements under the impact of α-particles, which through the light of intuition—and good technique—led them, in early 1934, to their beautiful discovery of artificia radioactivity. An interesting feature of this discovery is that it was so long in coming; for the phenomenon of artificial radioactivity had been expected, and sought for, since the earliest days o radioactivity. For this discovery the Joliot-Curie were awarded the Nobel Prize for Chemistry in 1935

About two years later, Mme. Joliot-Curie was appointed by M. Blum as Under-Secretary of State for Scientific Research. This office and her numerous other duties must have absorbed a great deal of her time and attention; moreover, her health was showing signs of having been affected by her exposure to radiation during years of work with strongly radioactive materials. But her scientific work continued without abatement. With P. Savić, she examined in detail the artificial radioelements produced by the irradiation of uranium by slow neutrons, analysing the products and identifying them chemically, and she came within a hair's-breadth of recognizing that the phenomenon involved in the production of these elements was that of fission. Then came the Second World War and the German occupation of France, during the last year or two of which she retired to Switzerland with her two children.

When the French atomic energy project was started in late 1945, she was appointed one of the four scientific commissioners, the others being F. Joliot-Curie, P. Auger and F. Perrin. When Joliot was dismissed in 1950 on account of his Communistic activities, she retained her post and served the full term of five years; but on the reorganization of the Commission early in 1951 she was no longer included. During these years she was the chief link between the Commission and the Institut du Radium and the University of Paris, and she served as the Commission's representative on several committees. She continued at the same time to publish work on various aspects of radioactivity, for her ardour for scientific research was such that neither administrative duties nor failing health could keep her from her laboratory.

Her parents were both persons of strong and independent mind, and Mme. Joliot-Curie inherited much of their character as well as their scientific genius. She had a powerful personality, simple, direct and self-reliant. She knew her mind and spoke it, sometimes perhaps with devastating frankness; but her remarks were informed with such regard for scientific truth and with such conspicuous sincerity that they commanded the greatest respect in all circumstances. In all her work, whether in the laboratory, in discussion, or in committee, she set herself the highest standards and she was most conscientious in the fulfilment of any duties she undertook.

She leaves with her husband two children—a daughter Hélène, married to a grandson of the late Prof. P. Langevin, and a son Pierre.

J. Chadwick

NEWS and VIEWS

New Foreign Member of the Royal Society: Prof. R. B. Woodward

Robert Burns Woodward, professor of organic hemistry in Harvard University and recipient of many honours, has now been elected a foreign member of the Royal Society. In 1937 he was awarded the degree of Ph.D. at the Massachusetts nstitute of Technology and shortly afterwards moved to Harvard University. His work there has ranged over almost the whole field of organic hemistry, and has had an outstanding influence pon the development of the subject, particularly during the past decade. His most important contributions have been concerned with the elucidation f the structure of natural products and their total ynthesis, and in this his views on biogenesis have been of great value. His synthesis of quinine 1944), followed by his brilliant work culminating in the first total synthesis of the steroids (1951), has reated a new era in synthetic organic chemistry. He has regarded the complexity of some natural products as a challenge, and this he has met by applying in masterly sequence the methods now available to the modern organic chemist. His recent otal synthesis of strychnine will always be regarded as a classical achievement. His work on the elucidation of the structure of natural products is characerized by the use of physical methods which are uitably complementary to the chemical methods of tructural investigation. He was a pioneer in the use f ultra-violet and infra-red spectroscopic techniques in structural work, and the present popularity of these methods is in some measure due to his influence; his rules concerning the ultra-violet spectral properties of various chromophoric systems are of great value. Many natural products have been forced to reveal the secrets of their molecular architecture as a result of Woodward's attentions, and these have included patulin, sempervirine, terramycin, aureomycin, magnamycin, ajmaline and cevine and related veratrum alkaloids.

Astronomy in the Australian National University: Prof. Bart J. Bok

Dr. Bart J. Bok, who has been appointed to succeed Dr. R. v. d. R. Woolley in the chair of astronomy at the Australian National University, will take to Mount Stromlo a detailed knowledge of the problems of galactic structure and stellar statistics, to which he can apply observations obtained with the new 74-in. reflector of the Commonwealth Observatory. At Harvard, Bok was closely associated with Harlow Shapley, and Bok himself took a particular interest in the problems of the southern hemisphere, visiting the Harvard Observatory at Bloemfontein, South Africa, to secure observations with the 60-in. reflector. As a consequence of the closing down of the Harvard Southern Station, Bok has recently turned his attention to radio astronomy, and his appointment to the chair at Canberra will no doubt strengthen the contact between astronomy at Mount Stromlo and the radio astronomy work of the Radio Physics Laboratory of the Commonwealth Scientific and Industrial Research Organization at Sydney.

Beit Memorial Fellowships for Medical Research

The following Beit Memorial Fellowships for Medical Research have been awarded for research work at the places indicated. *Fourth-Year Fellowship* (£1,000 a year): Dr. Evelyn E. B. Smith, synthesis of hyaluronic acid and of specific polysaccharides in pneumococci (Departments of Bacteriology and Biochemistry, University of Glasgow).

Junior Fellowships (£800 a year): Dr. R. J. Shephard, changes in the dynamic pressure volumes and in the vital capacity of the lungs in man, with the view of elucidating various types of dyspnœa (Department of Physiology, Guy's Hospital Medical School, London); Dr. J. R. Tata, normal and abnormal pathways of metabolism of the thyroid hormones (National Institute for Medical Research, Mill Hill); Dr. V. C. Abrahams, physiology and pharmacology of the hypothalamus, particularly in relation to the control of water balance (National Institute for Medical Research, Mill Hill); and T. F. Slater, enzymic constitution of the mammary gland in relation to lactation and, in particular, the synthesis of milk proteins (Department of Biochemistry, University College, London).

Institution of Mining and Metallurgy: Awards

THE Council of the Institution of Mining and Metallurgy has made the following awards: *Gold Medal of the Institution*, Dr. J. A. Bancroft, in recognition of his long and distinguished services to the mineral industry in southern Africa and in the advancement of the science and practice of economic geology; *Honorary Membership of the Institution*, the Hon. C. A. Banks, in recognition of his services to the mining industry, with particular reference to his pioneering work in the introduction of air transport for the equipment of poorly accessible mineral properties; the Right Hon. Viscount Chandos, for his services to metallurgical industries in the United Kingdom; and Mr. G. F. Laycock, past-president of the Institution, for his services to the mineral industry and to the Institution; *Consolidated Gold Fields of South Africa, Limited, Gold Medal* for the session 1954–55, Mr. J. F. G. R. Heywood, for his paper entitled "Pressure Manifestations at Great Mining Depths on the Witwatersrand" (*Trans. Inst. Min. Metall.*, 64); and *The Consolidated Gold Fields of South Africa, Limited, Premium of Forty Guineas* for 1954–55, Dr. J. J. Brummer, for his paper entitled "The Geology of the Roan Antelope Orebody" (*Trans. Inst. Min. Metall.*, 64); *William Frecheville Student's Prize* for the session 1954–55, Mr. F. M. Vokes and Mr. W. G. Jeffery conjointly for their paper entitled "The Geology of New Consols Mine, Cornwall" (*Trans. Inst. Min. Metall.*, 64).

Avogadro Centenary Commemoration in Rome

THIS year is the centenary of the death of Amedeo Avogadro, the Italian chemist and physicist whose discovery of one of the fundamental laws concerning the behaviour of gases brought him universal fame. To mark the occasion, the Accademia Nazionale dei XL, of which Amedeo Avogadro was a member, is organizing a commemoration ceremony which will take place on June 6 in Rome at the Capitol in the presence of representatives of the Italian Government and of foreign countries and prominent personalities from Italian cultural life. Appreciations of Avogadro's work will be given by Prof. Francesco Severi, president of the Accademia dei XL, Sir Cyril Hinshelwood, of the University of Oxford, president of the Royal Society, Prof. Linus Pauling, of the Institute of Technology, Pasadena, and Prof. G. B. Bonino, of the University of Bologna.

International Control of Pelagic Fisheries

AFTER discussion for several years, the International Law Commission last year agreed on rules to allow coastal States to prevent the fisheries near their own shores being exploited to the point of extermination by larger States. On May 2, *The Times* reported an attempt by representatives of Mexico and India to delete the provisions for compulsory arbitration included in the draft for the settlement of disputes. There are some resources such as oil, non-migratory fish, guano, weed and other marine products for which local jurisdiction seems reasonable. Others, such as whales, seals, salmon and other migratory fish, can be fished just as successfully in the deep ocean a thousand miles away. They are the same stocks as are fished at the coast and can be conserved only by international agreement. The work and success of the International Whaling Commission and the North Pacific Fur Seal Agreement are striking examples of how regulation and international co-operation can be achieved. It is clear from the report in *The Times* that the Law Commission and the General Assembly of the United Nations, while prepared to support well-founded claims, will not favour the general establishment of frontiers on the high seas. To the marine scientist such divisions of the ocean will be particularly objectionable. The usefulness of the seas and oceans to the small States as well as to the principal maritime powers depends ultimately on international co-operation in their study and use. The international councils, unions, and United Nations organizations will do more to improve the fisheries than is likely to be achieved by imposing too many local restrictions. There would soon be no whales off any coast in the southern hemisphere if it were not for active international co-operation in the Antarctic. The same co-operative spirit will eventually be needed in other pelagic fisheries.

Colonial Advisory Council of Agriculture, Anima Health and Forestry

THE Secretary of State for the Colonies, Mr. Alan Lennox-Boyd, has amended the terms of reference o the Colonial Advisory Council of Agriculture, Anima Health and Forestry which was first set up in 1929 and its membership has been altered to bring it in line with its new functions. The new terms of reference are as follows: (1) to keep under review the genera conditions of agriculture, animal health and forestry in the Colonial Empire and to maintain contact with the work of the Colonial Governments in these spheres of development; (2) to advise the Secretary of State or individual Colonial Governments at thei request upon general policy and development o particular aspects of policy and development in the fields of agriculture, animal health and forestry (3) to bring to the attention of the Committee fo Colonial Agriculture, Animal Health and Forestry Research in broad outline such problems in these fields on which research or investigation is required (4) at the request of Colonial governments to visit o make arrangements for visits by other than member of the Council.

The membership of the Council is as follows Lord Lloyd, Parliamentary Under-Secretary of Stat for the Colonies (*chairman*); Mr. W. B. L. Monson Assistant Under-Secretary of State, Colonial Offic (*vice-chairman*); Prof. W. I. B. Beveridge, professo of animal pathology, University of Cambridge; Mr. W. H. Cashmore, director of the National Institut of Agricultural Engineering; Mr. C. Clark, directo of the Institute for Research in Agriculture Economics, University of Oxford; Sir Geoffrey Clay agricultural adviser to the Secretary of State for the

Colonies; Mr. F. S. Collier, forestry adviser to the Secretary of State for the Colonies; Prof. M. McG. Cooper, professor of agriculture and rural economy, King's College, University of Durham; Dr. W. Davies, director of the Grassland Research Institute; Prof. A. N. Duckham, professor of agriculture, University of Reading; Sir Frank Engledow, professor of agriculture, University of Cambridge; Mr. G. Lacey, adviser on drainage and irrigation to the Secretary of State for the Colonies; Mr. D. Martin, of Unilever, Ltd.; Mr. R. S. Marshall, adviser on animal health to the Secretary of State for the Colonies; Mr. D. Rhind, Secretary for Colonial Agricultural Research; Sir William Slater, secretary of the Agricultural Research Council. The technical secretary of the Council is Mr. L. Lord, assistant agricultural adviser to the Secretary of State for the Colonies, and the secretary is Mr. A. S. Gann, of the Colonial Office.

Shortage of Scientific Workers in Great Britain

A PAPER entitled "Technical Education—Shortage of Scientists, Technologists and Technicians", prepared for private circulation by Mr. John Wellens (24 Mossley Road, Grasscroft, near Oldham, Lancs), comments on the Government's recent White Paper, suggesting that the White Paper offers little that is new and effective and supporting Lord Simon of Wythenshawe's recent proposal for a Royal Commission of inquiry. Mr. Wellens suggests that a Commission should be established and directed to report within six months. It should examine such major problems as the distinction between technologist and technician, the training appropriate to each, and the practicability or otherwise of training both in the same institutions. Mr. Wellens stresses that a number of questions demanding urgent examination are glossed over or ignored in the White Paper, and thus the Commission should also consider the quantitative demand and its relation to the demands of other sections of our national life, the extent of the existing wastage and its prevention, the avenues and opportunities of co-operation between education and industry in technical education, apprenticeship and its problems, the utilization of technologists, and the purpose and place of the technical schools. The Commission as a result would prepare a national policy or plan and recommend the type of agency required to see that the plan is put into operation.

Mr. Wellens does not refer to the 'sandwich' scheme of courses; but he himself recommends that the proposed central agency should be so equipped, staffed and financed as to have additional functions, such as research, the continuous collecting and dissemination of information and consulting services. It should be responsible for keeping permanently in touch with appropriate agencies in other countries and should function continuously and actively. Those universities with a major interest in technology should establish chairs of industrial education to promote independent research. Mr. Wellens's concern appears to be to obtain as a matter of urgency constructive answers to the vital questions which he indicates and which the Government has largely ignored.

History of Science in India

AT a meeting of the Council of the National Institute of Sciences of India, held in May 1955, the question of compiling a history of science in India was considered (*Sci. and Cul.*, 21, No. 8; February 1956). It was decided that this history, when written, should be divided into three periods, namely, the earliest years up to A.D. 1200, the medieval period A.D. 1201–1800 and the British period A.D. 1801–1950. It was also decided to invite the views of existing institutes and academies in the country which are in a position to undertake this type of work. These include the Bhandarkar Institute, Poona, and the Asiatic Society, Calcutta. The idea of writing such a history of science was first mooted in November 1951 at a symposium on the history of sciences in South Asia, held in Delhi under the joint auspices of the National Institute of Sciences of India and Unesco. At the symposium the National Institute was invited to convene a group to study the history of science in India. In view of the expenses which will be involved, the National Institute has decided to approach the Government of India for a grant under the Second Five Year Plan to undertake the project it has in mind.

Virus Transmission by Aphids

M. F. DAY has reported on experiments undertaken with the view of determining the mechanism of the transmission of the potato leaf-roll virus by aphids (*Austral. J. Biol. Sci.*, 8, 4, 498; 1955). He states that the virus causing potato leaf-roll can be recovered from the hæmolymph of *Myzus persicae*, the aphid vector. Infective virus has also been separated from the bodies of infected vectors. The virus can be transmitted by an aphid after a moult, and infectivity is retained for at least eight days; during this time the aphid is able to infect many plants. *M. persicae* is a much more efficient vector than *Macrosiphum euphorbiae*. Experiments suggest that the virus multiplies to a limited extent in *M. persicae*. When this vector feeds on a plant containing a low concentration of virus there is generally a latent period (of approximately 20 hr. at 25° C.) between the acquisition feed and a successful inoculation feed. When the vector feeds on a source of high virus concentration, occasional transmission is obtained with short (approximately 2 hr.) acquisition and inoculation feeds. However, the percentage of transmissions under these conditions with the local strain of *M. persicae* is lower than that reported by American workers. No clonal differences in vector efficiency were found. Attempts to isolate strains of leaf-roll virus with different vector relationships were unsuccessful. The relevance of these results to the mechanism of transmission of viruses by insects is discussed. It is suggested that the occurrence of a latent period in a virus vector is indicative of the passage of the virus from the midgut into the salivary glands via the hæmocœle, and the multiplication of the virus in that vector.

National Research Council, Canada: Awards for 1956–57

THE National Research Council, Canada, has made 269 awards for 1956–57, totalling 345,500 dollars in value. They include 65 bursaries (800 dollars each) and 155 studentships (1,200 dollars each), tenable in Canada. Of the awards for study abroad, twenty-seven special scholarships, worth 2,000 dollars each, have been granted which will be held in the following countries: fifteen in Great Britain, nine in the United States, two in Sweden and one in France. Twenty-two postdoctorate overseas fellowships, worth 2,500 dollars each, have been granted for work in the following countries: fourteen in Great Britain, three each in France and Switzerland, and one each in Germany and the Netherlands.

Second International Congress on Acoustics, Cambridge, Massachusetts

The Second International Congress on Acoustics will be held during June 17–23 in Cambridge, Massachusetts—at Harvard University and the Massachusetts Institute of Technology. At the same time the Acoustical Society of America will hold its fifty-first meeting. The Congress is sponsored by the International Commission on Acoustics, which is part of the International Union of Pure and Applied Physics. The main programme of the Congress will be based on three themes: bioacoustics and noise control—human responses to sound (including hearing, psychological response and biological effects) and methods of noise control based on these responses; architectural and musical acoustics—the production of music and speech sounds and the design of enclosures for good conditions of hearing; and physical acoustics and sonics—acoustical studies of matter, propagation of sound, and application of acoustical techniques to technical problems. There will be special demonstrations of speech analysis and synthesis, and a number of exhibits by scientific, technical and manufacturing organizations. Further information can be obtained from the secretary of the Congress, John A. Kessler, Acoustics Laboratory, Massachusetts Institute of Technology, Cambridge, Mass.

The Night Sky in June

New moon occurs on June 8d. 21h. 29m., U.T., and full moon on June 23d. 06h. 13m. The following conjunctions with the Moon take place: June 1d. 00h., Mars 8° S.; June 7d. 18h., Mercury 5° S.; June 10d. 05h., Venus 3° N.; June 13d. 15h., Jupiter 7° N.; June 20d. 11h., Saturn 3° N.; June 29d. 14h., Mars 10° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Aldebaran on June 23d. 08h., Mercury 2·5° N. Mercury is too close to the Sun during the greater part of the month for observation, but at the end of the month it rises at 2h. 45m.—an hour before sunrise—and may be seen for a short period, its brightness being greater than that of a first-magnitude star. Venus sets at 23h. 30m. at the beginning of June, but draws closer to the Sun and on June 30 sets only half an hour after sunset; its stellar magnitude varies from −4·1 to −3·4, and the visible portion of its illuminated disk decreases from 0·140 until it is in inferior conjunction with the Sun on June 22d. 06h. Mars rises at 0h. 45m., 0h. 10m. and 23h. 25m. on June 1, 15 and 30, respectively, and has an eastward movement in Aquarius; it increases in brightness during the month owing to a small increase in the visible portion of its illuminated disk and also to its distance from the Earth decreasing from 76 to 58 million miles. Jupiter, visible soon after sunset, sets at 0h. 25m., 23h. 30m. and 22h. 40m. on June 1, 15 and 30, respectively; its stellar magnitude varies between −1·5 and −1·4 owing to its distance from the Earth increasing from 520 to 557 million miles. Towards the end of the month it is close to Regulus. Saturn, in Libra, sets in the early morning hours—at 3h. 30m. on June 1, one hour earlier on June 15 and two hours earlier on June 30; its stellar magnitude varies from 0·3 to 0·5 owing to its distance from the Earth increasing by 20 million miles. No occultation of stars brighter than magnitude 6 occur in June. Summer solstice occurs on June 21d. 10h. 24m., and the total time of sunshine in the latitude of Greenwich is then approximately 16h. 40m. A total eclipse of the Sun occurs on June 8 and is visible as a total eclipse only in the South Pacific Ocean, maximum duration 4m. 45s.; it will be seen in New Zealand at sunrise as a partial eclipse.

Announcements

Dr. Lloyd P. Smith, at present chairman of the Department of Physics of Cornell University, has been appointed president of the Research and Advanced Development Division and vice-president of the Avco Manufacturing Corporation, of New York. The Corporation manufactures a wide range of electrical and electronic goods, including defence equipment for the United States Government.

The Ford Foundation has given two grants of 4,250 dollars (£1,517) each to the University of Cambridge to assist the work of Prof. M. Fortes, William Wyse professor of social anthropology, and of Mr. E. R. Leach, lecturer in the Department of Archæology.

The following three new members have been appointed to the Board of Regents of the Smithsonian Institution, Washington, D.C.: Dr. E. L. DeGolyer, a petroleum geologist and senior member of the firm of DeGolyer and McNaughton, Dallas, Texas; Dr. C. H. Greenewalt, a chemical engineer and president of E. I. du Pont de Nemours and Co.; Dr. C. P. Haskins, a research biologist and president of the Carnegie Institution of Washington. The Board of Regents of the Smithsonian Institution is by law composed of the Vice-President of the United States, the Chief Justice of the United States, three members of the Senate, three members of the House of Representatives, and six citizen members.

The second display of instruments, organized by the Scientific Instrument Manufacturers' Association at the Instrument Centre, 20 Queen Anne Street, London, W.1, was opened on May 22 and will continue for three months.

The Hydrocarbon Research Group of the Institute of Petroleum is arranging a symposium on "Vapour Phase Chromatography" during May 30–June 1, to be held at the Institution of Electrical Engineers, Savoy Place, London. During the meetings there will be an exhibition of apparatus. Further information can be obtained from the organizing secretary and treasurer, Mr. H. C. Rampton, c/o The British Petroleum Co., Ltd., Chertsey Road, Sunbury-on-Thames, Middlesex.

An exhibition of fishery equipment, including echo-sounders, has been arranged in connexion with the fourth meeting of the General Fisheries Council for the Mediterranean, to be held in Istanbul during September 17–22 (see *Nature*, May 5, p. 831). Exhibition space will be available, free of charge, and special arrangements have been made for the temporary import, duty free, of equipment for display. Firms wishing to exhibit equipment should write, before July 15, to Mr. Cihat Renda, Meat and Fish Office (Et ve Balik Kurumu Umum Müdürlügü), Selanik Cad. 78, Ankara, from whom further information can be obtained.

NORTHAMPTON POLYTECHNIC, LONDON

OPENING OF EXTENSIONS

IT is exactly sixty years ago since the Northampton Polytechnic, in St. John Street, London, E.C.1, was first opened to students, and therefore it was fitting that in celebration of its diamond jubilee the Minister of Education, Sir David Eccles, should have been invited to declare open the new extensions. Since 1896 there has been a number of improvements both by way of alterations and additions to the original building (established on a site given by the fourth Marquis of Northampton—hence the name of the Polytechnic), and also by additional buildings, for example, the Connaught Building in 1932 and its annexe in 1939.

The present extensions form the first phases of a comprehensive scheme of expansion of the Polytechnic and have been concerned with the provision of new laboratories and workshops for a wide variety of subjects, including: aeronautics; hydraulics; production engineering; instrument manufacture; instrumentation and process control; heat engines; advanced applied physics; high-voltage testing.

Provision has also been made for a new and magnificent library known as "The Skinners' Library". The Worshipful Company of Skinners was a joint founder of the College, and its continuing interest has been maintained not only by its financial grants, but also through its representation on the governing body, the chairman of which has invariably been a 'Skinner'. The furniture and fittings in the Library have been provided out of a gift from the Company of £5,000.

Other amenities in the extensions include the Great Hall, which has a seating capacity of 700, and refectories for staff and students which will accommodate more than 400 at a sitting. The total cost of rebuilding and re-equipment is of the order of £400,000.

The reopening ceremony was held in the Great Hall at 3 p.m. on May 7. The speakers in order were Mr. Hamilton Fulton, chairman of the Governing Body, Sir David Eccles, Minister of Education, Mrs. Helen Bentwich, chairman of the London County Council, and Mr. Beresford Ingram, vice-chairman of the Governing Body.

After welcoming the Minister and the guests, Mr. Fulton spoke on the work of the Polytechnic and its place in the educational system of Britain. He emphasized particularly the value of its status as an aided institution; while acknowledging that the bulk of the financial support of the College was due to the liberality of the London County Council, the Governors did enjoy limited funds of their own, and this ensured for them that liberty and autonomy essential for efficiency and enterprise.

Mr. Fulton spoke of present students as "the life blood of our competitive capacity against production in other countries and the ability of our technicians and our technological institutions to cope with competition, provided they have the necessary support of organized labour".

Although the Governing Body could not have known it, the timing of the opening ceremony was but a few days too soon, as the Minister in his speech revealed by his guarded response to the chairman's demand for some information regarding the future status of the College under the Ministry of Education plans for higher technology. The Minister stated that while he could not say anything in anticipation of the forthcoming debate on the White Paper in the House on May 1, it was obvious that the White Paper had been misunderstood in regard to the number of colleges to be designated colleges of higher technology. A very much smaller number would be so designated to form, as it were, foundation members of this top level of the four-tier structure to be established. While the Minister could not say in which level the Northampton Polytechnic would be placed, he added: "It seems to me to be the Senior Engineering Institution in London and therefore a place to which we will have to pay great attention. . . . Here you have a remarkable College which I know has a great reputation, but it is the sort of college which must do something for technical education as a whole as well as for its own students. You are the kind of people who can raise the flag and it is flags that people follow".

The guests, who comprised local dignitaries, representatives of City Companies, donors of gifts, principals of colleges, headmasters, representatives of professional bodies and industry, old students, past members of staff, and the present members of the Polytechnic—governors, staff and students—were afterwards shown the various laboratories and workshops, where exhibitions and demonstrations were staged. Of particular interest was a colour film taken by the staff of the Ophthalmic Optics Department showing the fitting and use of contact lenses. Other exhibits included demonstrations in applied physics, applied chemistry, electrical engineering, heat engines, hydraulics, aeronautics, watch making and repairing, instrument making, materials testing, automobile engines and vehicle maintenance, etc.

The purpose of the present extensions has not been so much to increase the number of students it is possible to accommodate as to improve the facilities for the existing enrolment. Thus, laboratories which hitherto have had to perform a double function, for example, heat engines and hydraulics, have been replaced by separate laboratories with much more adequate space for each different function. In turn, this has made it possible to increase the amount of equipment in these laboratories. Something of the order of £65,000 worth of new equipment has been added in the past three years and a further £85,000 worth is expected over the ensuing three years.

The more important pieces of large equipment include: a Ferranti Pegasus computer for the Mathematics Department; a full-size anechoic room for the Acoustics Laboratory; a supersonic wind tunnel for the Aeronautics Laboratory; a variable-slope water channel for the Hydraulics Laboratory; an electrode boiler and a Rover gas turbine for the Heat Engines Laboratory; high-voltage testing equipment for the Electrical Department.

As an exception to the foregoing, the National College of Horology and Instrument Technology, which is housed within the Polytechnic, has gained three rooms for additional workshops and laboratories in order that more students may be accommodated.

TECHNICAL EDUCATION IN GREAT BRITAIN

ON April 29 the National Union of Students held a conference in London at the Polytechnic, Regent Street, to discuss the recent Government report on technical education. The conference was attended by representatives from industry, local education authorities, the student associations in technical colleges, and the staffs of technical colleges. There were short opening addresses in each of the three sessions; but the major part of the time was devoted to discussion, which was lively and stimulating throughout. The morning session was opened by Mr. A. A. Part, Under-Secretary at the Ministry of Education, who spoke on "Action on the White Paper". He said that though the report in the White Paper made rather few specific proposals, it did envisage a wide extension of all advanced work in both full-time and part-time day courses at technical colleges, that is, all work above the standard of the Ordinary National Certificate or the Advanced Level of the General Certificate of Education; it also implied that, although a limited number of colleges selected from those with 75 per cent grant would be made into colleges of advanced technology, the total number of technologists studying at an advanced standard must be increased beyond the capacity of the establishments designated as colleges of advanced technology, and thus there would still require to be a number of colleges receiving 75 per cent grant which would mainly do advanced work.

One of the chief developments would be in the greater use of 'sandwich' courses. It is hoped that larger firms might pay the apprentices, whom they send on such courses, and that students from smaller firms might be helped by extra State scholarships and major county awards, all of which would in future be tenable at technical colleges doing advanced work. (It was not made clear whether this would apply only to colleges of advanced technology or to all colleges with 75 per cent grant.) Mr. Part said that, to find the extra personnel for the advanced courses, we must tap the large reservoir of talent among those who have left school before eighteen and that we must provide ways for these students to equip themselves for proceeding either to sandwich courses or Higher National Certificate courses, both by persuading parents to keep their children at school until they are eighteen and by encouraging a far greater liaison between schools, industry and technical colleges. The intention is to approve a large building programme: £15 million will be approved now, and in June a further £15 million for the session 1958–59. Local education authorities are responding well in sending in building schemes.

Mr. Part also emphasized the need for increasing the number of trained technicians, and in the discussion this point was emphasized by a speaker, who said that it was a mistake to 'hive' off the training of technicians from the major technical colleges. Another speaker said that technical secondary schools must be taken out of major technical colleges because this leads to the local residents thinking of the technical college as a boy's school and also prevents the atmosphere in the college from being that of an establishment for adult students. Mr. Part, in reply, promised that the schools would be moved out in the near future.

In the afternoon the conference was addressed by Sir Harold Roxbee-Cox, vice-president of the National Council for Technological Awards (the Hives Council). He said that the report of the Council, which is to be published very shortly, will suggest provision of an award of second-class honours degree standard to students who are successful in an advanced course approved by the Council, but that this approval implies that a course will be recognized only in a college which has a high general standard both in the quality of its staff, facilities for research and in social amenities for its students.

The U.S.S.R. is training three times as many technologists per thousand of population as Britain, and it is only because the British I.Q. (by which Sir Harold meant "inventiveness quotient") is, he believed, higher than that of most other countries, that our shortage of numbers is not more serious. He has made inquiries from industrial firms employing more than 50 per cent of the trained technologists in Britain, and from their replies he estimates that these firms would like to increase their numbers of technologists by one-third now; he believes that, in view of developments in the U.S.S.R. and the United States, there will ultimately be a much larger demand in Britain. For this reason, the expansion envisaged in the White Paper is not enough, and Sir Harold hopes the Government will accelerate and expand the facilities offered. He thought that in time those now taking external degrees at the technical colleges would be drawn into taking a course for a 'Hives' award, but the national need is to train more technologists in addition to those now taking external degrees in any technology.

Mr. Roland Oliver, student secretary of the National Union of Students, spoke on "Counter Balancing over Specialization". He stressed the necessity for retaining a balance between science and the arts in a school course and the advisability of allowing the student at a technical college more time during his course for private reading and meeting other students. Many speakers afterwards pressed that schools should not only give those taking science subjects at advanced level some training in the humanities, but should also give those taking arts subjects some training in science. These speakers felt that the proportion of headmasters and headmistresses with an arts training is far too large, and that this tends to make boys and girls follow an arts course rather than a science or modern course, and also to make for a lack of appreciation of the value of a scientific education and of the importance of the work of the major technical colleges.

The teaching at technical colleges came under heavy fire from some student representatives, who maintained that there was not enough lecturing, that the students were treated like schoolboys, and that the hours of class attendance were much too large and permitted of little private study. Some university student representatives said that the hours were just as long in many science and engineering faculties in the universities and that this was inevitable in view of the laboratory work required. One felt that the truth probably lay between these two groups of speakers and that there was room for some shortening of hours and some modification of teaching methods, though not quite as much as some speakers proposed.

Students also maintained that the best way of liberalizing the education of a technical student is to combine the shortening of hours of class attendance with a great increase in 'union facilities'. It was pointed out how small are the union club rooms in most colleges compared with those in a university, giving as an example for comparison the new building of the University of London, and many speakers urged that the Ministry should insist that, in any approved scheme for the enlargement of a technical college, provision should be made for adequate rooms for student activities. One could not help being impressed by this demand, which would have the strong support of college authorities.

Dr. J. Topping, principal of Acton Technical College, who took the chair throughout the conference, said in his opening remarks that more had been written on technical education since the Second World War than on any other subject, and he hoped that we are now moving into an era of action. The present writer came away feeling that there was every hope that his optimism was justified. As Dr. Venables puts it in his recent book on technical education: "We shall make progress, so long as those, who believe that the next stage in technical education is an evolutionary process, realize that we have not all of geological time available in this rapidly changing world".

Mr. F. Copplestone, president of the National Union of Students, who thanked all the delegates for coming to the conference, said that it had been a success because of the contributions the delegates had made. This is true, but it is also true that this success could not have been achieved without the initiative of the National Union of Students, which is to be congratulated on providing this opportunity for all the partners in technical education to meet.

H. V. LOWRY

INSTITUTE FOR SCIENTIFIC RESEARCH IN CENTRAL AFRICA, BELGIAN CONGO

REPORT FOR 1953

THE sixth annual report of the Institute for Scientific Research in Central Africa*, covering the year 1953, includes besides the report of the director, M. L. van den Berghe, brief reports from the presidents of the various scientific commissions and sections, lists of the sections, committees and commissions, with their membership, and a list of papers published during the year by members of the staff of the Institute and associated investigators; this last-mentioned list is supplemented by brief summaries of the papers. M. van den Berghe emphasizes the contributions which the work of the Institute has already made in the region of Belgian Central Africa in the field of physical and social anthropology, population statistics, the physics of high solar altitudes, biochemistry of foodstuffs and the experimental zoology of invertebrates, and refers particularly to the participation of the Institute during 1953 in a number of scientific conferences in Africa. The second Anglo-Belgian seminar in the human sciences was held at Kampala during February 23–28, 1953, and a third conference was due to be held in 1955 at Astrida and Lwiro. The first Anglo-Belgian seminar on nutrition was also held at Kampala, during February 18–20, 1953, and was concerned particularly with the comparison and discussion of results obtained in the field of nutrition in Uganda and the Belgian Congo and with visits to laboratories and institutions in Uganda and the exchange of techniques. A second seminar was projected at Lwiro in 1955.

A meeting of experts nominated by the Scientific Council for Africa South of the Sahara for the co-ordination of social research in Africa south of the Sahara met at Kampala during February 28–March 2, 1953. The conference recommended the publication of a series of brief accounts of the existing organization for social research and the appointment of an inter-African scientific correspondent to visit the different institutions and survey the work in progress in this field. Two further conferences in 1955 covering demography and economics, psychology, linguistics, ethnography and sociology were also recommended. An international conference for the protection of the fauna and flora of Africa was held at Bakavu in October 1953, and also an Anglo-Belgian Government conference at Kigali on the tsetse fly, at which it was agreed that the Institute should immediately commence a detailed study in the region of Kakitumba, including research on both *Glossina* and trypanosomes and the determination of the fly-belt.

Construction of the central library of the Institute at Lwiro was begun in January 1953, and a new station at Ituri, two hours from Lwiro, designed for the general study of tropical forest at a medium altitude, was planned for construction in 1954. The work of the Institute during the year included studies of the entomology of Ruanda-Urundi and ethnological studies among the Balega, which were designed to provide a course of lectures for the Colonial School at Brussels on aspects of parentage, family life and political structure and associations among the Balega. Measurements of solar energy in the visible spectrum were continued, and the equipment at Lwiro was further extended. The systematic and ecological study of the molluscs of Tanganyika continued, and the fauna of the north-east border of Lake Tanganyika was also studied, while investigations were commenced on the birds of Lake Kivu, and particularly of the seasons of reproduction of birds living nearly on the equator. The electrophoretic method is being used for studying the proteinæmia among indigenous races in Ruanda-Urundi and also the evolution of serum proteins in infants up to two years of age. Special attention was given to the study of kwashiorkor at Kivu, and a study was commenced of the factors influencing the productivity of the African worker in the Belgian Congo and especially in agriculture. Linguistic studies included a systematic one at Tshumbe, in the region of Mondja, of the language known as Otatela. To facilitate the collection and collation of neuropathological material autopsy services for neurological cases have been organized. Numerous observations have been made on nutritional disorders, tuberculosis and sickle-cell anæmia; and researches were continued on *G. morsitans* and the biotopes of *Culex sylvestres* and particularly *Aedes simpsoni*, the transmitter of 'jungle yellow fever' in

Uganda. Observations on *Caecobarbus geertsi* Blgr. in the grottoes of the Lower Congo were completed, and studies were commenced into the emigration of the Banyarwanda and Barundi in East Africa, and the institutions of Bukahê and Bugabire. A study of the geographical distribution of the fish of the basin of the Ruzizi was completed in the first five months of 1953, and investigations of the stratigraphy of the groups of Urundi and of Ruzizi led to some definite conclusions. Other investigations were concerned with the African *Histoplasma duboisii* Vanbreuseghem, 1952, with the science of malnutrition and kwashiorkor and with the paludism of mammals and their invertebrate hosts.

THE SMITHSONIAN INSTITUTION

REPORT FOR 1954–55

THE report of the Secretary of the Smithsonian Institution for the year ended June 30, 1955*, which is accompanied by the financial report of the Executive Committee of the Board of Regents and by reports from the branches of the Institution as well as by those in the Library and on publications, welcomes the enactment of legislation providing for the planning and erection of a new museum building for the Institution. Congress has already appropriated 2,288,000 dollars for the immediate planning of this Museum of History and Technology, for which 36 million dollars are authorized, and the new Museum will house all the national collections that record and illustrate the political, cultural, industrial, scientific and military development of the United States. As planned, it will be both a museum of United States history and a museum of science, engineering and industry, and a series of modern halls illustrating the principal periods of that history from Colonial days to the present is planned, with other halls showing the development of particular devices or subjects, such as automobiles, mining, medicine, manufactures, engineering and science. It is hoped that construction will begin in 1957. Preliminary architectural studies were made during the past year for the projected new National Air Museum, and further progress was made in renovating major exhibits at the Institution.

Visitors to the Smithsonian Buildings totalled 3,895,017—nearly 250,000 more than in the previous year—and, with the estimated 3,476,584 visitors at the National Zoological Park and 814,932 at the National Gallery of Art, brought the total number of visitors to the Smithsonian Institution to 8,186,533. The Institution continues to administer the Bio-Sciences Information Exchange, which is charged with preventing the unknowing duplication of research support by the Armed Forces and other Government agencies; and the Exchange, which has developed techniques to maintain a rapid interchange of concise information on the support of research in the bio-sciences, reports that it has been able to supply adequate information in response to all requests. Among the 7,600,000 specimens received by the National Museum during the year were collections of mammals from Korea, Pakistan and Panama; birds from Panama; large collections of fishes from the Gilbert Islands, Liberia and the south-eastern United States; the W. N. Mann collection of ants; 3,200 polychæte worms, mostly from New England; four hundred corals from the Great Barrier Reef; plant collections from Mexico, Central and South America; thirty-five specimens of meteorites, two thousand Silurian and Devonian fossils from Canada; some three and a half million mounted foraminiferan specimens; an early Curtis steam turbine; the Dodrill–G.M.R. mechanical heart and important electrocardiograph equipment. Field work included an investigation of the plant mites and other types of small animal life in the Belgian Congo; an ornithological survey of Panama; and the collection of larvæ of small moths of the genera *Depressaria* and *Agonopterix* in Wyoming and adjoining States.

The Bureau of American Ethnology made progress with its archæological work on Southampton Island in Hudson Bay, and Dr. H. B. Collins continued to supervise the "Arctic Bibliography" which the Arctic Institute is preparing for the Department of Defence, Vol. 4 being issued in August 1954. Besides preparing his report on previous field researches, entitled "Modern Inter-tribal Organizations on the North-West Coast", Dr. P. Drucker initiated a programme of archæological research at the important Olmec site of La Venta, Tabasco, Mexico. Dr. F. H. H. Roberts continued to direct the River Basin Surveys, the field investigations under which consisted mainly of excavations; no palæontological studies were carried out. By June 30, 1955, archæological surveys or excavations had been made in 243 areas in twenty-seven States since field work was started in 1946; and, of the 4,345 sites located and recorded, 852 were recommended for excavation or limited testing. At the end of the fiscal year, 324 sites in forty-four reservoir basins in seventeen different States had been dug extensively or in part, and further details of the work of the three field parties operating in the Missouri Basin are given in the report as well as of field work in the Garrison Reservoir area.

The Astrophysical Observatory, in co-operation with the United States Weather Bureau, continued the calibration of Eppley pyrheliometers, and the simplification and automatic recording of silver-disk pyrheliometry. Solar radiation studies at the high-altitude station at Montezuma in Northern Chile were hindered by sky pollution due to smelting operations at copper mines, and at Table Mountain in Southern California a gradual increase in the amount of smog from the Los Angeles area has been noted for some years. The work of the Division of Radiation and Organisms on the photo-control of the formative and development processes in seedlings of the bean plant indicated that the far-red energy interferes with development by acting on a product of the photochemical reaction initiated by the red energy. In studies with the root-tip cells of broad bean (*Vicia faba*), it has been found that, if exposure to X-rays is preceded by exposure to red visible light, the incidence of chromosome damage brought about by X-rays is reduced by 30–50 per cent, but if exposure to X-rays is preceded by exposure to radiant energy from the far-red or near infra-red, the damage is increased by 30–40 per cent. Using differential centrifugation methods to fractionate avocado fruit tissue it has also been found that the fraction remaining after sedimenting cell walls, nuclear material, mitochondria, plastids and other particles within this size range, contains an enzyme system which, on the addition of auxin, markedly reduces the consumption of oxygen.

* Smithsonian Institution. Report of the Secretary and Financial Report of the Executive Committee of the Board of Regents for the Year ended June 30, 1955. Pp. ix+173+7 plates. (Publication 4320.) (Washington, D.C.: Government Printing Office, 1956.)

The National Air Museum participated in celebrations of the fortieth anniversary of the founding of the National Advisory Committee for Aeronautics, and nearly twenty-two thousand photographs pertaining to aeronautics were added to the Museum's library of reference materials. Besides improvements in exhibits, the information services have been extended and are now meeting requests which have multiplied nearly two and a half times in three years. Accessions to the National Zoological Park totalled 2,347 individual animals, and 1,917 were removed by death, exchange or return to depositees. Of six hundred visitors to Barro Colorado Island during the year, forty-three were scientific workers who used the facilities of the station for research, particularly in biology and photography.

During the year the International Exchange Service handled 1,146,972 packages of government scientific and literary publications, consignments being made to all countries except China, North Korea, Outer Mongolia, the Communist-controlled areas of Viet Nam and Loas and the Haipang Enclave. The Smithsonian Library received 71,179 publications and arranged about 650 new exchanges; its holdings now total 951,409 volumes, including 585,592 in the Smithsonian Deposit in the Library of Congress. Publications issued by the Institution during the year totalled seventy-one, including seventeen papers in the Miscellaneous Collections, eight Proceedings Papers of the United States National Museum, four Bulletins of the Bureau of American Ethnology, and Vol. 7 of the Annals of the Astrophysical Observatory; 192,108 copies of the publications and 226,178 miscellaneous items were distributed.

MALADJUSTED CHILDREN

A COMMITTEE was set up in 1950 by the Minister of Education to inquire into the medical, educational and social problems relating to maladjusted children, with reference to their treatment within the educational system. The Committee has recently issued its report* and, despite much thought and labour, not unexpectedly offers no novel insight into the nature of maladjustment, or new and revolutionary ideas about the way it should be treated. Fifteen years ago the term 'maladjustment' was not in common use, and too little is still known about maladjustment in children and the ways it can be successfully treated to generalize or offer ready-made solutions. Instead, the Committee adopted the wiser, if more pedestrian, approach of considering, against the background of normal development, what is meant by a maladjusted child and what arrangements are at present available for treating and preventing maladjustment. These arrangements have been considered in relation to the education service, which itself occupies a central position inasmuch as it has continuous contact with most children for ten vital years of their lives.

One of the main difficulties which the Committee had to face was the definition of maladjustment. No one—except, possibly, the completely maladjusted—is completely adjusted to his environment; continual adjustment and re-adjustment are necessary throughout life. Maladjusted people are not necessarily unruly nor need they come into contact with the law; educationally backward and mentally retarded children do not provide all the maladjusted; intelligent people are also affected. What is known of the maladjusted is that they are insecure and unhappy, tend to get on badly in their personal relationships and may have failed to come to terms with their work.

The worst effects of maladjustment are seen in mental hospitals, divorce courts and prisons. At the end of 1954, for example, two-fifths of the 480,000 hospital beds available in England and Wales were occupied by mentally ill or mentally deficient patients. Surveys of factory workers have shown that 10 per cent had suffered from definite and disabling neurotic illness and a further 20 per cent from neurotic illness. It has been estimated that neurotic illnesses cause between a quarter and a third of all absences from work due to illness of any kind.

Although the worst effects of maladjustment are seen among adults, it is during childhood that most can be done to prevent maladjustment or to treat it. If one child can be helped, it will not only benefit his family and the community but may also have repercussions on future generations; maladjustment begets maladjustment.

The attention of the Committee has rightly been focused on those agencies which affect children. The part which the education service, particularly the school, has to play in the prevention, discovery and treatment of maladjustment is of great importance. The education service does not work in isolation, however, but co-operates with many other agencies. Collaboration is particularly close between the school health service and the hospital service, which provides a number of child guidance clinics and makes available the services of psychiatrists for many clinics run by local education authorities. Co-operation between these two services and the maternity and child welfare service is also necessary if the problems of children under five are to be adequately tackled. It is often in these early years that the seeds of future trouble are sown or the first symptoms appear, even though they may not be noticed until a child goes to school. The Committee has considered these and other agencies and made suggestions which will enable the psychological, educational and medical treatment of maladjusted children to develop on lines which seem the most rewarding.

One of the main suggestions is concerned with the work of the child guidance service. Much of the work at present done by local education authorities is too compartmentalized. The school psychological service, the school health service and the child guidance clinic should work more closely together. The educational psychologist, for example, should, wherever possible, try to help, within the setting of the school, those children who have learning or behaviour difficulties. Instead, as so often happens, of being concerned only with selection tests for the 11+-examination, he should spend part of his time in the child guidance clinic. Nor should the facilities of a child guidance service be withdrawn from a boy when he leaves school. The Committee rightly recommends that the service should be available for boys and girls in or out of school until they have reached the age of eighteen, when they are officially recognized as mature. A valuable suggestion is that parents should have direct access to all child guidance clinics without their children having first been seen and recommended by some intermediary;

---

* Ministry of Education. Report of the Committee on Maladjusted Children. Pp. vi+180. (London: H.M.S.O., 1955.) 6s. net.

this, fortunately, is already the case with the majority of clinics.

The Committee's recommendation for the educational provision of maladjusted children should be received with enthusiasm. It will not only save considerable money but will also be of greater service to maladjusted children than existing facilities. At present there are day special schools or classes specifically of maladjusted children in the areas of only three local education authorities. Over the country as a whole, little day provision has been made. Recent psychological findings indicate that there are obvious advantages in leaving a child in his own home during treatment. Since the restoration of harmony and understanding between parents and children must be one of the main purposes of treatment, it is most satisfactory to treat a child, if possible, while he remains in the natural environment of his own home. Treatment of him and of his parents can then go hand in hand; and there is no danger of a conflict being set up in his mind between the different standards of two environments. The co-operation of parents may be much easier to secure if their child can stay at home than if he is sent to a boarding establishment.

For maladjusted children local education authorities should make more use of day 'special' schools and part-time 'special' classes. No child should be sent to a boarding establishment if his education can be satisfactorily continued from home. The teachers should be allowed sufficient time for keeping in touch with the parents, the child guidance service and the ordinary schools from which the children come. All teachers of backward children will support the recommendation that staffing should be based on the principle that ordinarily a teacher cannot satisfactorily meet the needs of more than ten maladjusted children, and that for some purposes a group may need to be considerably smaller. No day or residential school should contain less than about twenty children nor more than about fifty. Strong support will be given to the recommendation that the Ministry of Education and local education authorities should constantly review the need for studying more maladjusted pupils over the age of eleven, "in particular boys with I.Q.'s below 85–90% and children suited to a grammar or a technical school course". Local education authorities should also consult with one another and other bodies to develop facilities for maladjusted children on a regional basis.

In the case of children whose activities lead to their appearance in juvenile courts, considerable care should be taken to see that the children are indeed maladjusted before being treated as such. A recent suggestion of the Magistrates' Association to the effect that meetings should be encouraged between magistrates, staffs of child guidance clinics and others connected with psychiatric work would be a valuable means of ensuring that court sentences would have greater prophylactic value. In general, too, support should be forthcoming for the Committee's recommendation that every child appearing before a juvenile court who is so handicapped as to need special educational treatment in a boarding school should be provided with residential treatment by the local education authority rather than be sent by the court to an approved school.

After outlining the size of the problem and practical measures needed to combat it, the Committee turns to the all-important but difficult task of developing a positive approach to mental health in the community as a whole. A number of its recommendations should be carried out forthwith. There should be, for example, close co-operation between child guidance clinics and child welfare centres. The function of health visitors should be modified, and they should be trained to advise parents on behaviour, nervous and other difficulties in children, as well as on matters of physical health. More clubs and discussion groups for parents should be established by schools, including nursery schools. Above all, the fundamental importance of the family as a whole should be borne in mind by those responsible for strengthening and developing the social services, and action designed to keep the family together should be regarded as one of the most important aspects of prevention.

The most valuable feature of this report is the way the Committee has made its way through the tangled mass of legislation and opinion which surrounds the problem of maladjusted children and has made recommendations which are practicable and attainable. Many of the recommendations will be very costly to carry out; but many of them will cost a lot more if they are not carried out. What is first needed is the building up of attitudes of mind required for the prevention and treatment of maladjustment. The five years taken to prepare this report will have been well spent if the thinking part of the community becomes familiar with its main arguments.

PSYCHOSOMATIC RESEARCH AND BEHAVIOURAL SCIENCE

It is not often that one has the opportunity of reviewing two new journals and finding them of excellent quality within their respective fields. Both are quarterlies. The first, the *Journal of Psychosomatic Research*[*], is to be devoted mainly to clinical studies if the present contents are an indication. These vary from such work as "Emotions and the Peripheral Vasomotor System" to "The Sedation Threshold as an Objective Index of Manifest Anxiety in Psychoneurosis". There are other papers on asthma and peptic ulcers. Such research should direct the attention of the obstinately organically minded to the importance of mental states, and the psychologically orientated to the fact that the mind does not work *in vacuo*.

The scope of the other journal, *Behavioral Science*[†], is stated in the introductory editorial. The editors ask: "Can the scientific method solve the larger, more pervasive questions about man as well as the smaller, more particular ones? Is the tool with which man has won his victories over the physical world applicable to uncovering the laws which govern man's conduct, the deepest causes of our strife and our harmony? If fragments of multiple sciences were brought together in a unitary behavioral science and all the separate skills focused on the study of human behavior, perhaps the time required to find the answers to these questions could be reduced. The uniformities among disciplines could be recognised;

[*] *Journal of Psychosomatic Research*, 1, No. 1 (1956). Pp. 96+2 plates. (London and New York: Pergamon Press, Ltd.) £5 (14 dollars) per year, or 70*s*. (9.80 dollars) for individual subscribers certifying that the journal is for their private use.

[†] *Behavioral Science*, 1, No. 1 (January 1956). Pp. 82. (Baltimore, Md., and Ann Arbor, Mich.. Mental Health Research Institute, University of Michigan.) 6 dollars per year or 1.75 dollars per issue

better communication among them established; generalities of findings magnified; additional benefits derived from comparing theories in diverse fields, explaining similarities and differences, and the validity and applicability of empirical work increased by planning individual studies as components of an explicit mosaic of research strategy."

The result of this wide plan has been, perhaps inevitably, that the papers tend to be mainly mathematical. This may be valuable since there is a limit to clinical research, and without the aid of other sciences psychology and psychiatry will reach an impasse. The papers here suggest that there is little danger of this. They range from "Biological and Cultural Evolution" to a "Critique of Stochastic Models for Learning". This journal will be a joy to the mathematician and no doubt will draw many into the study of behaviour who would otherwise treat it as too vague to be of interest.

CLIFFORD ALLEN

THE NEED FOR OBSERVATIONS IN THE OLDER BRANCHES OF ASTRONOMY

FOR his presidential address last year to the Royal Astronomical Society and since published (*Mon. Not. Roy. Astro. Soc.*, 115, 2; 1955), Dr. J. Jackson took as his subject "The Need for Observations in the Older Branches of Astronomy, especially Double Stars", and discussed three branches with which he has been associated for about forty years: double stars, stellar parallax and meridian astronomy. After the First World War Dr. Jackson did a considerable amount of work on double stars, collecting and discussing the observations made during the preceding thirty years. The observing programme at that time was largely restricted to the Struve stars, but now that many new double stars have been catalogued and that there has been a great decrease in the number of observers, it is necessary, said Dr. Jackson, to review the position. Sufficient knowledge regarding the average masses and distances of ordinary stars is now available to decide on those stars that are worth observing at intervals of twenty years and to distinguish them from those that cannot be expected to eveal orbital motion of more than a degree or two n a century.

The importance of this is shown by the following onsiderations regarding the Σ stars. These were all picked up during 1824–27 with a 9½-in. refractor from among the hundred and twenty thousand brightest tars north of Dec. − 15°, and while the original list contained more than three thousand double tars, after various adjustments and rejections there emained 2,659 brighter than about magnitude 9 nd with a separation less than 32″. Before these were put on the Greenwich observing list, most of them had been observed at several epochs, and when Dr. Jackson discussed them in 1922 he found as follows: relative motion was shown by 649, undoubted orbital motion by 449, mere optical doubles in 161 cases, and in 39 pairs showing rather large elative motion it was difficult to decide whether they ormed binary or optical systems; it is suggested that while the majority probably belonged to the atter class, some may have been true binaries with a rather large parallax which could be confirmed by trigonometrical observations. A very important point is that 2,010 of these stars showed no certain relative motion of the components, and the great majority of these must be real binaries with periods of many thousand years, as Dr. Jackson shows by an analysis of the figures. His conclusion is that the 2,010 stars which had shown no relative motion by 1920, although true binaries, scarcely need any further attention until the end of this century. The 449 showing orbital motion, and also the 39 for which the nature of the motion is uncertain, should, he thinks, be observed at intervals of ten or twenty years until an orbit can be computed or the pair proved merely optical.

Turning to the OΣ stars, which were discovered with the 15-in. refractor at Pulkovo mostly during 1841–42, Dr. Jackson said that, owing to the closeness of the components and relatively greater difference in brightness than those just considered, they are more difficult to see and observe accurately. Hussey re-observed them with the 12-in. and 36-in. refractors at Lick Observatory, and when Dr. Jackson discussed them in 1923 he found that 135 showed orbital motion, 15 were optical systems, 5 showed motion of uncertain nature, and 270 showed no motion. In spite of the fact that these stars had been observed over a shorter interval of time than the Σ stars and, in addition, accurate observation was more difficult, yet they contained a greater percentage of stars of importance for the future, a fact which is attributable to the stars being closer and the components brighter. Dr. Jackson's final remarks on the subject were: "I therefore conclude that one of the most urgent needs of observational astronomy at the present time is the systematic re-observation of important double stars for which we have already detected the beginnings of orbital motion. The position may not be quite so bad as it appears as there may be a number of measures of double stars not yet published, and the absence of a general catalogue giving observations later than 1927 makes it difficult to estimate the true position. Nevertheless the reports of the International Astronomical Union do indicate a steadily decreasing number of measures". (After preparing his address, Dr. Jackson became aware of the measures of many close double stars made by Dr. Muller, of Strasbourg, during a four months visit to Lick Observatory, and a footnote to the published address directs attention to this, with a short account of the first orbits calculated for thirteen double stars.)

The position with regard to parallax determinations is very satisfactory when compared with that about half a century ago. In Newcomb's book "The Stars", published in 1904, there is a list of seventy-two stars for which parallaxes were known; of these, there were fifteen about which it was noted that the results were subject to more doubt than usual, and one was stated to be entirely unreliable. In contrast to this, the Yale Observatory published in 1953 a "General Catalogue of Trigonometric Stellar Parallaxes", which gives the parallaxes of 5,822 stars from about ten thousand determinations; this is the outcome of the great international scheme, devised about forty years ago by Schlesinger, for the mass determination of parallaxes, and was taken up at a dozen observatories which had long-focus telescopes. Several of the telescopes which have completed their programmes are at present used for the intensive observations of the nearest stars in the search for companions which are too close or too faint to be discovered except by the periodic displacement of the centre of light. A number of stars have been found to have companions which move in orbits with periods of a year or two. It is suggested that parallax observations for the next few years may be confined to filling in the gaps made by the omission of stars of early and late types, to the observation of certain specific stars, such as double stars or Vyssotsky's stars with dwarf characteristics, and to unravelling some of the larger discordances.

In the final part of his address, devoted to meridian astronomy, Dr. Jackson pointed out that at present the Royal Greenwich Observatory alone in Britain carries out observations with the meridian instrument for determining stellar positions. Several factors have contributed to this diminution of meridian observations in different countries, among which the economy of photography is important, and some may ask what justification there is for meridian astronomy. The answer is that, while we need accurate positions of only sufficient stars for reducing photographic plates, we require the proper motions of as many stars as possible, of every degree of brightness, of every spectral type, of every kind of variability, and in all galactic longitudes and latitudes, and all this involves the positions at two or more epochs. To determine the average distances of groups of stars too far away for trigonometrical calculations, proper motions are necessary, and they are thus important in investigations concerning the content of the Milky Way system at distances exceeding a hundred parsecs, in addition to showing the systematic and random motions of the stars themselves. This led Dr. Jackson to a discussion of the fundamental systems used, of certain disadvantages inherent in some and also of various ideas for improvements. His address ended with a short account of a very important aspect of meridian astronomy—namely, accurate time determinations—in which the Royal Observatory plays a prominent part, and the results of the photographic zenith tube in action are awaited with interest.

BRITISH JOURNAL OF RADIOLOGY

SIXTIETH ANNIVERSARY

THE May issue of the *British Journal of Radiology* is its diamond jubilee number. The *Journal* is the direct descendant of the *Archives of Clinical Skiagraphy*, which was the first journal to be devoted entirely to radiology. Its first number was dated April 2, 1896; but apparently it is not clear whether it was actually published then or in May of that year.

The *British Journal of Radiology* has had a great influence throughout the world in the development of medical radiology in its widest sense, and the jubilee number includes a number of historical reviews of particular interest. Prof. G. Stead deals with the contributions of physics to the progress of radiology during the past sixty years. It is perhaps singularly fortunate that many leading physicists have always devoted a great deal of effort to the advancement of the applications of physics to medicine. The first presidential address to the Roentgen Society, given by Silvanus Thompson, was apparently a remarkable beginning. Sir Oliver Lodge published a course of six lectures specially designed for medical practitioners. In the present number, Sir John Cockc writes on "The Future Role of Atomic Energy Industry, Science and Medicine", Dr. Russell Reynolds reviews sixty years of radiology, and James T. Case summarizes the evolution of mod radiology. A point of historical interest is that 1879 Sir William Crookes, without realizing it, apparently obtained X-rays in the course of experiments and had sent fogged photographic pla which had been stored near his vacuum tubes, b to the manufacturers as defective. The account X-ray apparatus by Mr. Cuthbert Andrews is illu inating. On the historical side, he mentions t "bound in the 1897 volume is what is undoubte the forerunner of our modern successful suppleme —A Supplement to the Archives of the Röntgen R entitled 'Radiography in Marine Zoology— British Echinodermata', by Dr. Wolfenden". particular interest to radiotherapists are the revi by Dr. N. S. Finzi on radiotherapy and Dr. Lacassagne on radiobiology.

The development of British radiology has depen upon a number of factors. Among the most import of these are probably the recognition of the value consultation in medicine with special reference to many aspects of radiology, the applications of phy to both radiodiagnosis and radiotherapy and interest throughout the years shown by many clini radiologists in those aspects of fundamental scie now called radiobiology. It is clear that the *Bri Journal of Radiology* has played a great part facilitating these developments.

ROCKEFELLER FOUNDATION GRANTS

THE National Academy of Sciences, Washingt has initiated a study of the possible biologi dangers to present and future generations of expos to atomic radiation. 250,000 dollars has be awarded by the Rockefeller Foundation for t project. A biophysics research programme on cultivation of individual animal cells has be devised by Dr. Theodore Puck and his associates the University of Colorado, towards which Foundation has made an award of 85,000 dolla The Foundation has made a research grant of 60, dollars to Drs. J. J. Christensen and W. M. My for their work in the University of Minnesota connexion with wheat stem rust. Research on genetic factors of intelligence and emotional variati in dogs, directed by Dr. C. C. Little at the Roscoe Jackson Memorial Laboratory, Bar Harbor, Mai receives a first-quarter grant of 50,000 dollars.

Dr. Edwin D. Kilbourne, of Cornell Univers Medical College, is working on latency or activati of viruses, towards the expenses of which Foundation has granted 48,000 dollars. The Univ sity of Chicago is to receive 50,000 dollars for programme of training in statistics for scientis The State Institute for Human Genetics, Upsa Sweden, has been awarded 50,000 dollars. The wo will be shared with the University of Upsala and Royal Agricultural College. Prof. A. Rossi-Fanell work at the Institute of Biological Chemist University of Rome, will be supported over a peri of four years by a grant of about 30,000 dollars, a that of Prof. P. Desnuelle at the Institute of B logical Chemistry, University of Aix-Marseille, over a period of five years by a grant of 25,000 dollars.

Research in biomathematics under Dr. Irwin Bross, of the Cornell University Medical College, is to be supported by a five-year grant of 50,000 dollars.

Among other grants made by the Rockefeller Foundation for the first quarter of 1956 are the following: Prof. T. Park, University of Chicago, experimental ecology, 10,500 dollars; National School of Agriculture and Livestock, Managua, Nicaragua, laboratory and field equipment; Prof. F. Buchthal, University of Copenhagen, physiology, 14,000 dollars; Institute of Pharmacology, University of Padua, virology, 10,000 dollars; Prof. S. Bezzi, University of Padua, organic chemistry, 10,000 dollars; University of Florence, Institute of Botany, 9,000 dollars; University of Utrecht, Biophysical Research Group, 12,000 dollars; Prof. Per F. Scholander, University of Oslo, experimental biology; Royal Veterinary College, Sweden, equipment for animal physiology.

Numerous grants towards travelling and study expenses and towards the costs of various congresses were also made. Forty-five fellowships were awarded in the following subjects: agriculture (23), biology and medicine (5), humanities (5), medical education and public health (7), social sciences (5).

OVULATION DURING DELAYED IMPLANTATION AND OTHER REPRODUCTIVE PHENOMENA IN THE BADGER (*MELES MELES* L.)

By PROF. R. J. HARRISON

Anatomy Department, London Hospital Medical College, E.1

AND

E. G. NEAL

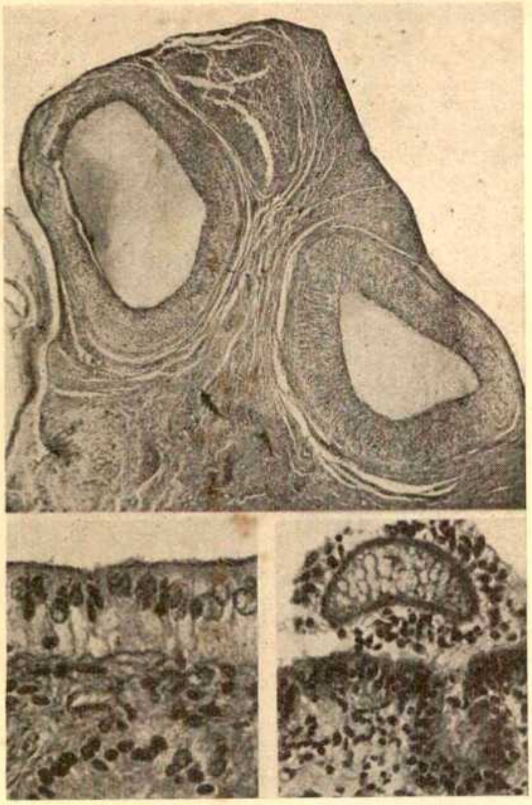
Biology Department, Taunton School, Somerset

REPRODUCTION in the European badger has been the subject of controversy for many years, and one authority or another has made claims for each month of the year to be that of the mating season. Those investigators[1-3] who have recently examined the reproductive pattern comment at ength on the prolonged period of delayed implantation. Fischer[1] calculated from embryological data obtained from badgers in Germany that mating took place during July–September, that implantation delay of from 4 to 5 months) occurred in December and January and that cubs were born during January–March. Notini[2] stated that in Sweden mating occurred in May, that implantation was delayed for seven to eight months and that the cubs were born in March. Preliminary observations by Neal[3] in south-west England suggested that mating occurred not only in April and May, but also during July–September. Implantation usually occurred in December and parturition followed within sixty days. All these investigators have recovered blastocysts or mbryos at different times of the year, but none has made an exhaustive histological examination of the ovaries and reproductive tract, or counted the orpora lutea.

Since the date of the first report, Neal[3] and his ollaborators have maintained intensive observation f the numbers and behaviour of badgers at various ocalities in Gloucester and Wiltshire, but mainly n the Quantock Hills, Somerset. More than fifty nimals, cubs and adults, were obtained for disection as the result of being run over by motor-cars, illed by badger-diggers, keepers or pest-control fficers. The specimens were difficult to obtain, nd have taken nine years to accumulate, but he series covers the entire cycle and pregnancy xcept for July. The ovaries have been serially ectioned, and sections of the reproductive tract ave been examined. The uterus of each animal was carefully opened and searched or washed out for blastocysts, and serial sections were cut of the uterine tubes of those animals that had recently ovulated.

Examination of the fixed material indicates that the reproductive pattern in the badger is complex and variable. Maturing, mature and recently ruptured follicles are present in the ovaries in February and March, but the earliest date for recovery of blastocysts is April 30, 1955. During April–July the average number of blastocysts is 2·3 per animal (range 1–3); the number of corpora in these animals averages 4·0 per animal (range 3–6). The excess of corpora may be explained by not finding all the blastocysts or by loss due to degeneration. Twice as many animals (13) during this period had corpora in varying stages of development or retrogression (average 4·0 corpora per animal, range 2–7), but no ova, cleavage stages or blastocysts were found. In June, animals with blastocysts in the uterus and an equivalent number of corpora in the ovaries also possessed large, maturing follicles.

During the period August–December many differences can be detected; all but one of twenty adult females had blastocysts (average number 3, range 2–5) in their uterine horns. There is a significant rise in the average number of corpora to 6·2 per animal (range 2–11), and maturing follicles were also present in animals killed in late September. An adult female killed on October 16, 1954, gave an explanation for the findings. Four recently ruptured follicles and five retrogressing corpora lutea were present in the ovaries; of the latter, two corpora looked more degenerate histologically than the other three. Three healthy blastocysts were in the uterus, and in serial sections of one uterine tube there were two degenerate and apparently unfertilized ova. This and other similar examples indicate that the number of corpora increases during the period of delayed implantation due to ovulation during delay, and there is evidence from several animals that it can occur more than



(*Above*) Section of part of one ovary from a badger killed on October 16,1954, showing two young corpora and an older one. × 13. (*Lower right*) One of two degenerating ova present in the uterine tube of the same badger; there were three unimplanted blastocysts in the uterus. × 180. (*Lower left*) Tall columnar epithelial cells of the uterine mucosa during delayed implantation. × 440

once. Ovulation does not necessarily always occur for the first time in the spring, since evidence was found of sets of young corpora in June, September and even October, that were associated, in each specimen, with an equal number of blastocysts. Several animals killed in June, September and October showed thick, stratified and cornified vaginal epithelia, possessed maturing follicles, and had varying numbers of corpora and blastocysts. Others, sometimes killed on the same day as one of the above, lacked follicles, had only a low transitional vaginal epithelium, but possessed just as many corpora and blastocysts. During January and February a few pregnant animals were killed; the average number of embryos per animal was 3·1 (Fischer's material gives an average number of 2·7 and Notini's 2·5 per animal). Observations on the number of cubs after birth in south-west England give an average of 2·25 cubs per sow (8 singles, 22 twins, 8 triplets, 5 quadruplets). The average number of corpora lutea per animal during pregnancy is 6·5 (range 2–11). Thus no accessory corpora appear to be formed after implantation. The corpora present in each pair of ovaries from October to the end of pregnancy have similar characteristics, are twice as large as those of delay and are better vascularized. Rejuvenescence in the corpora lutea and the immediate pre-implantation changes in the uterus are heralded by increased vascularization and hyperæmia in these organs. Corpora lutea persist until the end of pregnancy, but show signs of involution at mid-pregnancy. They degenerate rapidly during lactation.

It therefore appears that the female badger in south-west England, having reached maturity during its second year, can either (*a*) ovulate for the first time in the early months of the year and have up to nine months delayed implantation during which up to three further ovulations may occur, (*b*) ovulate for the first time during the summer or autumn, perhaps exhibit further ovulations, and thus have a delay of implantation varying from two to six months.

There is no evidence of replacement of blastocysts, and little to suggest addition during the period of delay. The blastocysts exhibit similar characteristics throughout the period, with a large perivitelline space, and showing some evidence (as Notini[2] found) of slow but steady increase in size. The blastocysts are irregularly placed along the uterine horn during delay, and may even be found bunched together either at the proximal or distal ends of the uterine horn; spacing along the horn seems to occur just before implantation.

The uterine mucosa reacts scarcely at all to the ovarian events until implantation, and thus appears to be less sensitive to the prevailing hormonal environment than the vagina. Little secretory activity in the uterine glands can be seen, and the greatest detectable change is in the lining epithelium of the uterus, which appears to pass through cycles of changes from low cubical to high palisade, mucified columnar cells with the nuclei varying in position It is quite possible that it is these cells that are providing nutriment for the blastocysts during delay.

The histological and embryological findings fit in very interestingly with the observations of behaviour Sexual excitement is greatest during the period February–May, and at other times takes the form of short isolated nights with long periods in between where no interest of any kind is shown. From mid-May to mid-July the badger shows least sexual activity, and feeding occupies its activities. Mating has been observed by Neal and his collaborators during the main period of sexual excitement, late March–May, and again during July–September Attempted matings were observed during February and March and in early October.

It would appear that the corpora of delay are not active producers of progestins, and that there is no evidence to support an argument that corpora accumulate as the result of additional ovulations during delay until their combined progestin secretion is sufficient to induce implantation. In fact, the corpora of delay are all characterized by varying degrees of vacuolation in the cytoplasm of the lutea cells and even by fairly advanced cellular degeneration. The evidence from badgers kept isolated in captivity[2,4] proves that a period of delay of eight months is quite possible (there are even records of females giving birth after being kept isolated for thirteen and fifteen months), and suggests that the mating stimulus is not necessary to precipitate implantation. No vaginal smears were prepared from these animals and thus the possibility of spontaneous ovulations or even of the existence of a definite ovarian cycle during delay cannot be ruled out Lactation does not appear much to influence the events; it lasts about four months and has virtually ceased by the end of June. Increase in the length of day has been suggested[5,6] as a factor inducing implantation in the mink, but it is difficult to consider this a factor in the badger. The animal lives mainly in a deep burrow during the day, emerges in the dusk and is virtually nocturnal in its habits ; further, our evidence suggests that implantation in many animals must occur before the days start to lengthen. The age of the animal does not influence much the reproductive pattern, since both young and old females display delay ; there is slight evidence from two older females that there had been an increase in the number of times follicles had ruptured during delay.

It is felt that insufficient attention has been directed to the part that may be played during delay by the adrenal and by the interstitial tissue of the ovary. In the badger, the latter tissue is well developed, particularly in the cortical region, and is curiously invaded by numerous communicating epithelial tubes. These intra-cortical tubes sometimes extend from openings on the surface of the ovary to the hilum, where they may anastomose with the rete ovarii. They are reminiscent of the sub-surface crypts of the covering epithelium described by Harrison and Matthews[7] in a wide variety of mammals, but are developed to a degree much greater even than that observed in Pinnipedia. The cortical interstitial tissue passes through a distinct series of cytological changes during delay, and histochemical techniques strongly suggest it to be active during this time ; it reacts to a variety of techniques more strongly than any other component of the ovary.

A detailed account of all the aspects of reproduction elicited from the observations on behaviour and examination of the fixed material will be presented shortly.

ORGANIC PEROXIDES AND MUTAGENIC EFFECTS IN *DROSOPHILA*

By Dr. F. H. SOBELS
Genetisch Instituut der Rijksuniversiteit, Utrecht

Mutagenicity of Dihydroxydimethyl Peroxide and the Mutagenic Effects of Formaldehyde

It has been suggested[1] that the mutagenic action of formaldehyde may be related to that of organic peroxides. The fact that a mixture of formaldehyde and hydrogen peroxide is a much stronger mutagen for *Neurospora* conidia than either substance alone has been attributed to the formation of an organic peroxide, dihydroxydimethyl peroxide, HO—CH_2—O—O—CH_2—OH [2]. According to Jensen *et al.*, even pure formaldehyde solutions exercise their mutagenic effect on *Neurospora* by way of peroxide formation.

In *Drosophila* a mixture of formaldehyde and hydrogen peroxide did not produce more mutations than formaldehyde alone[3]. This may be due to the high catalase content of the body fluids of the fly. Catalase inhibition has been used to test the idea that peroxide formation plays a part in the production of mutations by formaldehyde injections into *Drosophila*. The result supported this assumption ; for a given dose of formaldehyde produced twice as many mutations in males which had been pretreated with sublethal doses of cyanide vapour than in flies not so treated[4].

Mutations in *Drosophila* have been produced by direct application of organic peroxides by Altenburg[5], using tert.-butylhydroperoxide, and by Sobels[6], using dihydroxydimethyl peroxide. The latter substance is of particular interest because of its probable implication in mutagenesis by a formaldehyde – hydrogen peroxide mixture, and it has therefore been studied in more detail.

The compound was synthesized by Mr. M. J. D. van Dam, of the Department of Organic Chemistry, University of Utrecht, by the reaction of formaldehyde and hydrogen peroxide in ether[7]. All solutions contained 0·7 per cent sodium chloride in distilled water and were buffered at *p*H 6·6. 0·28 mm.^{3} of such solutions was injected into the abdominal cavity of wild-type Oregon-*K* males characterized by a spontaneous mutation-rate of 0·2–0·3 per cent. The treated males were afterwards tested for the incidence of sex-linked lethals by means of the Muller-5 method. Preliminary observations were made on the pattern of sensitivity in the gonads of the treated males by mating them individually to three fresh virgin Muller-5 females at specific intervals. The successive broods arising in this way then represent successively younger stages of spermatogenesis at the time of treatment.

Four different concentrations of dihydroxydimethyl peroxide were used. Those with the higher doses showed that it is a fairly potent mutagen for mature spermatozoa. A 0·04 *M* solution, which is highly toxic, produced 1·7 per cent lethals in 662 chromosomes from sperm used during the first three days after treatment. A 0·02 *M* solution produced 3·6 per cent lethals in 471 chromosomes from sperm utilized on the first day after treatment. In the latter experiment, spermatozoa which had been utilized from the second to the fourth day were also tested for lethals ; they carried only five lethals in 662 chromosomes (0·8 per cent). Still later broods were not examined.

The lowest concentrations of dihydroxydimethyl peroxide were, on the contrary, ineffective on mature spermatozoa, but resulted in an increased mutation-rate in the third brood produced from the seventh to the tenth day after treatment. After treatment with 0·0138 *M* dihydroxydimethyl peroxide, this brood contained 1·3 per cent lethals in 933 chromosomes, and after treatment with a 0·015 *M* solution it contained 1·8 per cent lethals in 439 chromosomes. It thus appears that at some stage during spermatogenesis, sensitivity to the mutagenic action of dihydroxydimethyl peroxide is even higher than in mature spermatozoa.

The present finding that dihydroxydimethyl peroxide, like formaldehyde, induces mutations in mature sperm supports the hypothesis[4] that formaldehyde exerts at least part of its mutagenic effects via the formation of an organic peroxide. In addition to their action on mature sperm, both dihydroxydimethyl peroxide and formaldehyde[3] produce mutations in earlier stages of spermatogenesis. This further similarity suggests that the formation of a peroxide may also be involved in the mutagenic effects of formaldehyde on earlier stages of sperm development. It cannot yet be decided whether the same is also true for the mutagenic action of formaldehyde, if fed to the larvæ, in which case mutations were obtained only in the auxocyte stage preceding meiosis[8].

In view of the enhancing effects of a cyanide pretreatment on formaldehyde mutagenicity, the effects of cyanide on peroxide-induced mutation-rates were studied. Such pretreatments did not enhance the mutagenic effects of strong doses of dihydroxydimethyl peroxide; a slight effect in the first brood after injection of the low doses is not excluded, however. This result can perhaps be interpreted by assuming that after administration of dihydroxydimethyl peroxide the fly is provided with the ready-made product, whereas in the case of formaldehyde, catalase-inhibition favours accumulation of the peroxide.

Finally, it may be mentioned that one daughter of a male treated with dihydroxydimethyl peroxide carried a mutation to an allele of white in part of her gonads. This observation of delayed action brings dihydroxydimethyl peroxide into line with other chemical mutagens[9].

I am much obliged to Mr. M. J. D. van Dam for his co-operation in synthesizing the dihydroxydimethyl peroxide preparation.

Effect of Pretreatment with Dihydroxydimethyl Peroxide on the Rate of Mutations induced by X-rays

Previous observations showed an enhancement of the rates of mutation induced by X-rays after pretreatment with cyanide and azide[1]. This finding suggested that increased production of hydrogen peroxide, due to inhibition of the cytochrome and catalase enzyme systems, made the genetic material more sensitive to the effects of radiation. The fact that pretreatment with formaldehyde likewise enhanced the genetical effects of X-rays (unpublished work) supports this assumption, because formaldehyde also inhibits catalase and in addition produces mutations, presumably through the formation of an organic peroxide (see above).

For a further test of the idea that the presence of increased amounts of a peroxide enhances the effects of irradiation, flies were pretreated with an organic peroxide, dihydroxydimethyl peroxide.

Oregon-*K* males one to two days old were injected with low concentrations of dihydroxydimethyl peroxide and placed under the X-ray apparatus immediately afterwards, the average time between injection and irradiation being 13 ± 10 min. X-radiation was by a General Electric, Maximar 100 model of the dermatology clinic of the University of Utrecht at 100 kVp., 5 m.amp., 1 mm. aluminium (half-value thickness: 1·3 mm. aluminium) and 240 r. per minute. Simultaneous exposure of pretreated and X-ray control flies to the irradiation was possible by the use of different indian ink marks on their thorax. The preparation of the dihydroxydimethyl peroxide solutions and the genetic methods employed were essentially similar to those described before (see above).

Table 1 (upper half) presents the results of two experiments in which males were mated one day after treatment and afterwards changed to three fresh Muller-5 females per male every three days. It will be seen that, as in previous experiments, dihydroxydimethyl peroxide by itself in low concentrations had only a negligible effect on frequency of mutation in the first two broods, but exercised a definite mutagenic action on some earlier stage of spermatogenesis, which in these experiments furnished spermatozoa for the third brood. In the two

experiments in which it was combined with irradiation, an effect of the pretreatment was apparent only in the second brood, where it was statistically highly significant. It remained significant after correction for the possibility that the mutagenic effect of dihydroxydimethyl peroxide by itself, which in the controls occurred in the third brood, was in these experiments shifted to the second.

With the mating scheme used, the second brood in X-ray experiments is usually drawn from the most sensitive stage in spermatogenesis and yields the highest frequency of mutation after irradiation[1,2]. It s this stage which responds most clearly to the potentiating action of cyanide and azide on X-ray mutagenesis (Fig. 1). The present results, therefore, seem to bring pretreatment with dihydroxydimethyl peroxide in line with those earlier experiments. Unfortunately, however, sperm utilization in the present experiments was not as had been expected, and had resulted in unusual brood patterns of mutation-rate. In R_1 the peak occurred in the third brood, in R_2 there was no clear peak at all. In R_1 at east it seemed possible that the high mutation-rate in the second brood of the pretreated series was due not so much to an effect of dihydroxydimethyl peroxide on X-ray mutagenesis as to a change in the rate of sperm utilization, as a result of which the stage most sensitive to the peroxide alone furnished sperm for the second brood. Even on this assumption, there remains a real excess of mutations in the pretreated series. Thus the enhancing action of dihydroxydimethyl peroxide on X-ray mutagenesis seems well established by these experiments; but the question whether this action is exercised at the same stage as those of cyanide and azide could not be decided from them.

A third experiment was therefore carried out with a mating scheme which, it was hoped, would result in a clearer separation of the stages of spermatogenesis. Four broods were raised, covering successively three, two, one and three days. A smaller X-ray dose and a lower concentration of peroxide were chosen than in the previous experiments, the former to guard against sterility and saturation at the most sensitive stage, the latter in order to minimize the mutagenic action of the peroxide by itself. The results are set out in Table 1 and in Fig. 2. Under these conditions, mutation frequency after irradiation without pretreatment rose slightly from the first to the second brood and reached a decisive peak in the third. The potentiating effect of dihydroxydimethyl peroxide started in the second brood and was most pronounced in the third; χ^2 was significant for both broods. Dihydroxydimethyl peroxide by itself, on the other hand, produced a slight mutagenic effect only in the fourth brood, when mutation frequencies in the two irradiated series had already dropped below the initial level. These results lead to the conclusion that dihydroxydimethyl peroxide, like potassium cyanide and sodium azide, enhances the mutagenic effect of X-rays mainly or perhaps exclusively during the sensitive stage, while its own mutagenic effect is exercised on some earlier stage.

The marked similarity between the enhancing effects of dihydroxydimethyl peroxide and those of potassium cyanide and sodium azide supports my earlier hypothesis that, after pretreatment with the latter substances, increased amounts of peroxide were responsible for the greater mutagenic action of the radiation. In this connexion the results of Stone *et al.*[3] on carbon monoxide poisoning before and after irradiation of *Drosophila virilis* are of great interest. They found that, due to inhibition of the cytochromes, an increase in the X-ray-induced translocation-rates in this species is most pronounced

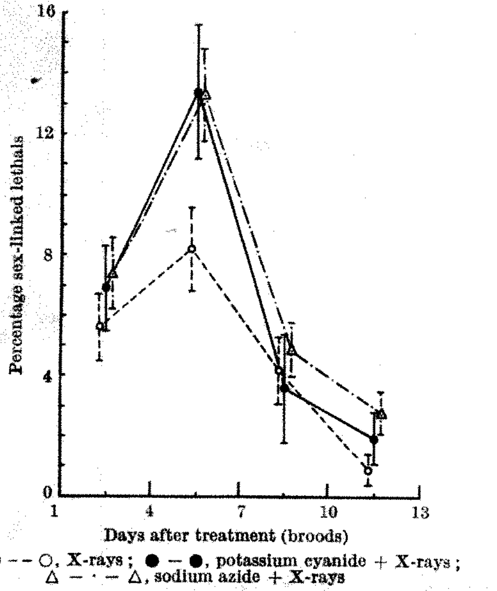

Fig. 1. Frequency of sex-linked lethals in successive broods from males which had been injected with solutions of cyanide (0·008 *M*) or azide (0·003 *M*) prior to X-irradiation with 1,700 r., as compared with that from males receiving X-rays only

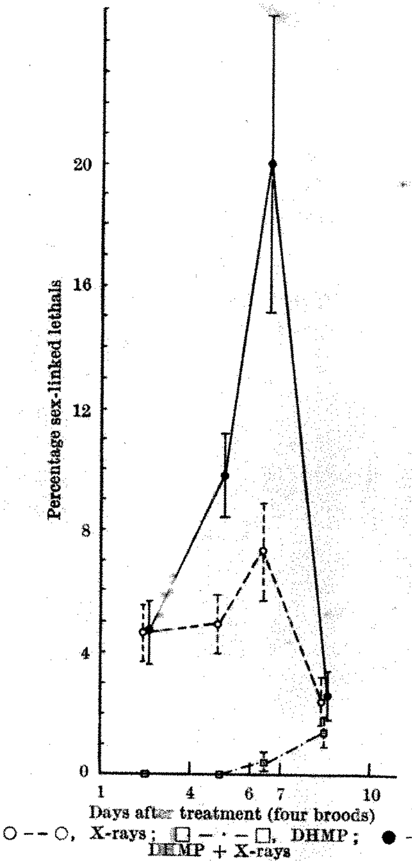

Fig. 2. Frequency of sex-linked lethals in successive broods from males which had been injected with 0·0138 *M* dihydroxydimethyl peroxide prior to X-irradiation with 1,511 r., as compared with that from males which were irradiated or injected only

at a stage corresponding to stages of peak sensitivity to the mutagenic effects of irradiation in *D. melanogaster*.

The present observation that one particular stage of spermatogenesis, characterized by peak sensitivity to the mutagenic action of X-radiation, also shows a preferential response to pretreatment with an organic peroxide and other compounds which are thought to act via peroxide formation, suggests that the two phenomena may be related. They support the view put forward by Auerbach[4] for the mutagenic action of mustard gas, that at the sensitive stage some new mechanism for mutagenesis is added to that which acts on mature spermatozoa, this new mechanism presumably being connected with biochemical conditions prevailing in immature germ cells, but no longer in ripe ones. Altogether, then, it seems a reasonable assumption that the formation of peroxides accounts for at least part of the mutagenic action of X-rays on the genetic material of *Drosophila*.

TESTS OF PURITY OF DIPHTHERIA TOXINS BY ELECTROPHORESIS IN STARCH GEL

By M. D POULIK

Department of Hygiene and Preventive Medicine, University of Toronto, Canada

I HAVE previously reported on the purification of diphtheria toxoid by filter-paper electrophoresis and continuous electrophoresis methods[1,2]. Three components were obtained, two of them possessing no biological activity as demonstrated by the immunoelectrophoretic method introduced by me in 1952[1]. Recently I have separated highly concentrated and purified diphtheria toxins and toxoids as well as tetanus toxoids into several components by electrophoresis in starch gel[3].

Since the actual concentrations of the materials are low, photography of these gels is very difficult in spite of the fact that the components are clearly visible by viewing them in reflected or transmitted light. The results from only a few of the materials tested will be presented here. Fig. 1 shows the photograph (*A*) of a starch gel in which the diphtheria toxoid from the Connaught Laboratories was separated. Five components (*M*, *N*, *O*, *P*, *Q*) stained with amido black 10*B* can be seen. Under the photograph is a diagram (*B*) of the same pattern. All other results described in this communication are represented by similar drawings. The biological activity of the components obtained was demonstrated by flocculation in agar gel using the technique of immunoelectrophoresis already mentioned[1]. The result is represented graphically by a series of flocculation lines (Fig. 1,*C*); each of the components shows at least two. Component *X* gave two flocculation lines in spite of the fact that it could not be demonstrated by staining methods. In the same figure the protein pattern obtained with toxin purified by Lepow and Pillemer[4] is shown with the corresponding lines of flocculation. This material is fraction *E*-2-2 containing 6,850 Lf./ml.; 2,350 Lf./ mgm. nitrogen; 2·80 mgm. nitrogen/ml. (Lepow, I. H., communication to Dr. D. T. Fraser). Seven clearly visible components were obtained and also three additional components perceptible by transmitted light (Fig. 1,*D*). The corresponding flocculations are drawn below (Fig. 1,*E*). The number of the stained components and the number of the flocculation lines correspond to the number of flocculation lines found by carrying out the flocculations in agar[5]. It is felt, therefore, that most of the components

Fig. 2. Shading same as in Fig. 1; vertical dotted lines: probably present

proposed by Dr. S. G. Pope *et al.*[5] are demonstrated by the present technique.

Fig. 2 shows graphically results obtained with toxins *TD*-3/51 and *TD*-8/51 obtained from the Statens Serum Institut of Denmark through the courtesy of Dr. Inge Scheibel and with a toxin obtained from the Wellcome Laboratories through the courtesy of Dr. Pope. The latter material, designated *MS*-605/7, contained 1,540 Lf./ml.; 2,900 Lf./mgm. protein nitrogen; 2,610 Lf./mgm. total nitrogen. After at least three further crystallizations, this material would give a single flocculation line in agar gel (communication to Dr. D. T. Fraser[6]).

Since the number of components differs in toxins from different laboratories, an attempt was made to determine the purity of Pope's toxin by interaction with serum. During studies (unpublished) of the binding capacity of diphtheria toxin by polyvinylpyrrolidone, albumin and serum, it was observed that the filter-paper electrophoresis pattern of normal serum (Fig. 3,*D*) is disturbed when mixed with toxin (Figs. 3*A*, *B*). The space between albumin and alpha-1 is widened, the 'alpha-1 globulin' fraction is increased in amount and the 'alpha-2 globulin' fraction is decreased. By flocculation in agar gel the toxin was localized in the alpha-1 globulin position[1]. It can be seen that both toxins *TD*-8/51 (Fig. 3,*A*) and *TD*-3/51 (Fig. 3,*B*) influence the pattern in the same way. The percentage distribution of the components was measured by an electronic computer[7] and the results are given on the left-hand side of each serum pattern. The toxin of Lepow and Pillemer was also found to have similar properties. The changes were induced even when the toxin was diluted 1 : 500 (1·9 Lf./ml. of serum in the case of *TD*-8/51). Pope's toxin, when mixed with the serum, was also localized in the region of alpha-1 globulin (Fig. 3,*C*) but did not change the pattern. A striking example of this interaction of toxin with the serum proteins was obtained by mixing the toxins with a nephrotic serum (Fig. 3,*H*) in which the alpha-2 globulin was markedly increased. The photograph shows that a significant portion of the alpha-2 globulin was removed (Fig. 3*E*, *F*) by the toxins and shifted to the beta-globulin region, thus producing a heavy band. The distance between alpha-1 globulin and albumin was again increased. Here also the toxins were localized by flocculation in the alpha-1 globulin region.

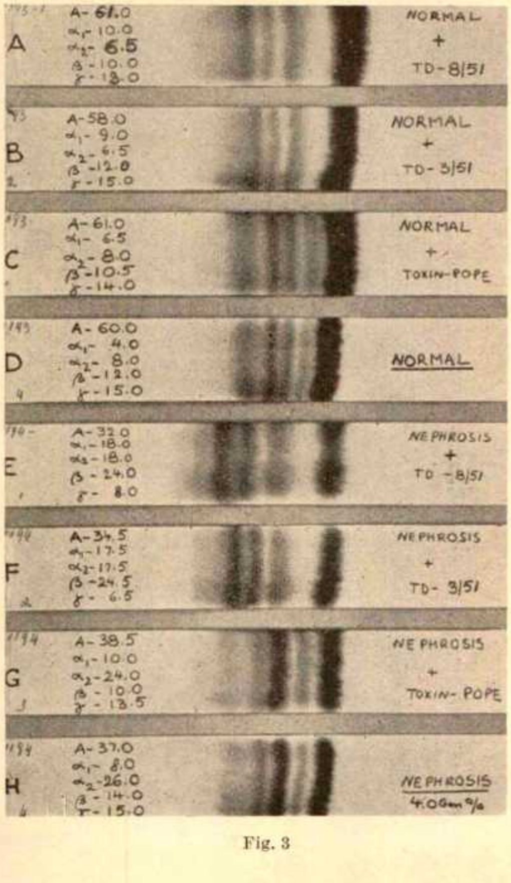

Fig. 3

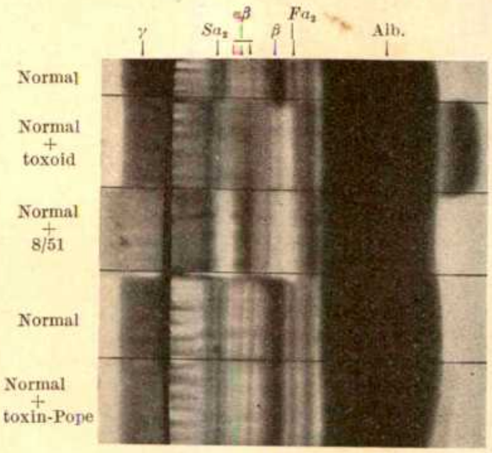

Fig. 4

The failure of Pope's toxin to induce the change in serum protein pattern described for the other toxins is apparent by comparing pattern *C* with pattern *D* and *G* with *H* in Fig. 3. It is therefore concluded that substances missing in the preparations *MS*-605/7 and present in the other toxins are responsible for this change. The sole component of *MS*-605/7 in starch gel gave two flocculation lines by the immunoelectrophoretic technique, and this toxin must be regarded as much more purified than the others.

More detailed information about the fractions involved in these changes was obtained by subjecting the mixtures to electrophoresis in starch gel[3]. A mixture of serum with toxoid was also included, in order to illustrate its effect on the serum protein pattern.

Fig. 4 shows a photograph of a large gel in which the mixtures were applied side by side and subjected simultaneously to the same electrophoretic conditions. Disregarding the photographic blemishes, it is evident that Pope's toxin induces no change in the main protein pattern. On the other hand, toxin *TD*-8/51 involves not only the subfractions of alpha-2 and beta-globulins, but also gamma-globulin. A detailed discussion of these various interactions will be given at a later date.

This work was supported by a Federal Public Health Grant. I am indebted to Dr. O. Smithies for the comparative experiment in the large gel and to Mr. C. Smith for the photographs. [Feb. 22

Metal Whiskers

'Whiskers' are small crystals which grow from the surface of several metals. It is believed that their structure is to an unusual degree free from imperfections[1]. Whisker growth from the free edges of tin plate is affected by stress in the tin, both growth-rate and whisker population being increased[2]. Hasiguti[3] has suggested that whisker growth is a means of reducing stress when general extrusion is inhibited. In the present work evidence has been obtained that extrusion must be obstructed if whiskers are to form. Thus on compressing a 3-mm. slab of an alloy containing small particles of tin dispersed in aluminium, profuse growth of whiskers occurred over the whole exposed tin surface (Fig. 1).

Growth of a whisker ceases abruptly at a length independent of pressure[2]. It has now been observed that after a crop of whiskers has been wiped from the tin plate a further set will grow. After twelve cycles of growth and removal a few sources remained active, and some sources produced a total whisker length of about 1 cm. although individual whiskers were rarely as long as 1 mm. There was sometimes an 'incubation period' of a few days before growth recommenced on a source.

When the sources in a surface had been exhausted, grinding away 20μ from this surface made fresh growth possible.

Near the melting point of tin, growth is more rapid and whiskers are longer (up to 5 mm.).

Electron micrographs of carbon replicas of tin whiskers showed star-shaped cross-sections to occur in those of smaller diameters (Fig. 2). Thicker whiskers appear as bundles of thinner ones: using the optical microscope, striations along the length of some of these were seen and occasionally they branched toward their tip.

It appears difficult to account for such properties as the abrupt termination of growth, a constant growth-rate and the reactivation of sources by a dislocation mechanism involving climb only. It is now proposed that whiskers are generated mainly by a glide mechanism; but that the frequency with which the whisker generating dislocations operates depends on diffusion: this will still give the linear relationship between growth-rate and pressure[3]. This model will be discussed in detail elsewhere.

Microwave Detection of Metallic Ions and Organic Radicals in Plant Materials

In numerous plant substances we have detected strong electron-magnetic resonances from manganese ions (see Fig. 1, for example). The manganese resonance can be immediately recognized by its six-line hyperfine structure resulting from the manganese nuclear interaction (spin 5/2). In all plant materials in which it was found, the multiple spacing was exactly that for manganese ions in aqueous solution (component separations of 95 gauss). Since the manganese multiplet spacing in crystals has been found to depend upon crystalline fields, we conclude that the manganese ions which we have found in plants may be dissolved in their water content.

Note the single sharp line with $g = 2{\cdot}00$ superimposed on the manganese hyperfine structure for pine cone and pine needle in Fig. 1. In pine needles picked up from the ground, this single resonance appeared much stronger relative to the manganese resonance. Possibly its greater strength relative to the manganese structure came about because the fallen needles had lost some of their water content. We have observed similar resonances in fallen oak leaves, naturally dried ivy stems, and other apparently dead plant materials.

The sharp single resonance observed in these experiments, which is apparently like that observed by Commoner, Townsend and Pake[1] in many lyophilized substances, may in some instances arise from bound or semi-bound oxygen. We have identified a similar resonance[2] of bound oxygen in irradiated 'Teflon'; but for plants which generate oxygen, a controlled experiment to test this hypothesis is more difficult.

A third type of resonance we have observed in several plant materials is illustrated by Fig. 2. This

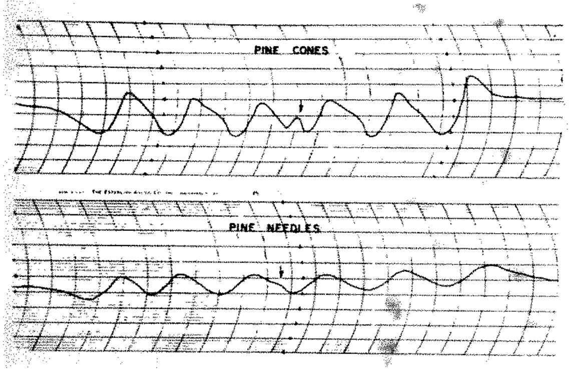

Fig. 1. Paramagnetic resonance of various plant materials at room temperature. The six equal components occurring for all have a total spread of 475 gauss (component-spacing 95 gauss). This sextet arises from manganese ions of the plant. The source of the additional resonance indicated by arrows is uncertain. It may arise from organic free radicals or from trapped oxygen. The curves were obtained with an Esterline-Angus recorder. Low-amplitude magnetic modulation of the absorption line was employed, synchronized with a phase-lock-in detector and amplifier. The curves do not represent the true line shape but approximately the first derivatives of the actual absorption curves. That for pine needles was obtained at 9 kMc./s., the other at 23 kMc./s. The centre of the patterns (points indicated by the arrows) represents the position of the free electron spin resonance

s a broad resonance with a g factor of 2·06. In the stems of oak leaves we found the manganese resonance superimposed on the broader resonance. In cotton eaves no manganese resonance is evident. We are not yet certain of the origin of the broad resonance; but we tentatively attribute it to cupric ions. The g factor of 2·06 is exactly that found by Ingram and Bennett[3] for the copper derivative of chlorophyll. We have found an identical resonance in a commercial sample of chlorophyll. We suggest that this resonance in the commercial sample, as well as the similar ones in Fig. 2, indicates an occasional substitution by certain plants of copper for magnesium in their chlorophyll. Such substitution may depend on many factors, such as the condition of soil and season.

Our preliminary observations reported here were made at room temperature on materials simply taken from the plant, or the ground below, and placed directly in the absorption cell. Certainly at lower temperatures and perhaps at room temperature resonances of other metallic ions should be observable. The method should become a convenient tool for plant physiologists or agriculturists.

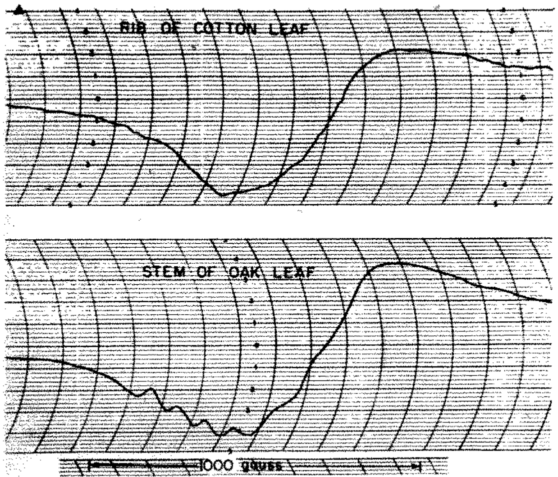

Fig. 2. Paramagnetic resonance at 23 kMc./s. in certain plant materials. The curves were obtained as described for Fig. 1, except that the amplitude of modulation was increased, and the scale condensed to favour detection of a broader resonance. The broad resonances here are believed to result from cupric ions in the plant. The g factor is 2·06. The structure superimposed upon the broad resonance for oak leaves arises from manganese ions

Structure of 3 : 4-Benzpyrene

3 : 4-BENZPYRENE is one of the most potent carcinogenic compounds. It is the active cancer-producing agent in coal-tar and in the tars produced during the combustion of many organic materials. It crystallizes in two forms (*a*) monoclinic and (*b*) orthorhombic. The unit cells and space groups of both forms have already been determined[1]. (In this earlier work the compound was called 1 : 2-benzpyrene; but the nomenclature was afterwards changed.) The monoclinic form has now been investigated in more detail.

The structure was solved by a combination of the trial-and-error method with that of Fourier transforms. Two-dimensional Fourier syntheses were calculated on the following zones, ($0kl$), ($hk0$), ($h0l$) and (hkh). In addition, a bounded projection on (010) of $\frac{1}{4}$ of the unit cell was calculated. The atomic co-ordinates were refined by successive F_0 syntheses followed by $(F_0 - F_c)$ syntheses on the ($0kl$) and (hkh) zones. It is interesting to note that in the ($0kl$) zone where every atom is well resolved, the co-ordinates obtained by repeated $(F_0 - F_c)$ synthesis refinement agreed very closely with those obtained by applying to the F_0 Fourier map the corrections given by the method used by Burns and Iball[2] for chrysene. In this latter method each electron-density peak position obtained from an F_0 synthesis is corrected for the effect of neighbouring peaks in the projection.

The observed structure factors were obtained from equi-inclination Weissenberg photographs by eye-estimation of the intensities. The calculated structure factors were obtained by using the scattering curves of McWeeny[3] for carbon and hydrogen, with temperature factors (B) of 3·42 and 4·75 for carbon and hydrogen respectively.

The crystal data are as follows: $a = 4{\cdot}535$ A., $b = 20{\cdot}40$ A., $c = 13{\cdot}49$ A., $\beta = 97{\cdot}0°$; space group $P2_1/c$; 4 mol. ($C_{20}H_{12}$) per unit cell, density observed = 1·351 gm./c.c., calculated = 1·352 gm./c.c.

Fig. 1 shows the Fourier projection on the plane perpendicular to the a-axis. Only a few atoms are resolved in each of the other projections calculated.

The following reliability indices $\left(R = \frac{\Sigma|F_0 - F_c|}{\Sigma|F_0|}\right)$ indicate the agreement between the observed and

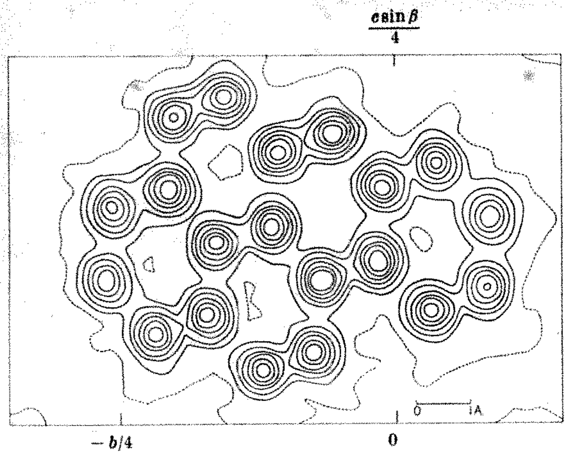

Fig. 1. Electron-density map of projection on plane perpendicular to a-axis. Contours at intervals of one electron per A.^{2}; the one-electron contour is dotted

calculated structure factors, $R(0kl) = 0{\cdot}12$, $R(hk0) = 0{\cdot}17$, $R(hkh) = 0{\cdot}17$.

The position of the molecule in the unit cell can be given by stating the co-ordinates of atom S (Fig. 2), which are $x/a = 0{\cdot}200$, $y/b = -0{\cdot}112$, $z/c = 0{\cdot}268$.

The equation of the mean plane of the molecule is

$$0{\cdot}770\,x' - 0{\cdot}602\,y - 0{\cdot}222\,z' - 0{\cdot}891 = 0$$

where x' is parallel to a, y is parallel to b and z' is perpendicular to the plane (001).

This molecule is not as planar as the molecules of some of the other condensed-ring hydrocarbons. The mean deviation of the carbon atoms from the above plane is 0·037 A. and the deviations of four atoms are rather larger than was expected. They are: $M = 0{\cdot}087$ A., $R = -0{\cdot}067$ A., $Q = -0{\cdot}067$ A. and $E = 0{\cdot}101$ A.

The bond-lengths calculated from the latest co-ordinates are given in Fig. 2. There are two abnormally short bonds IJ and AR, and one very long one, RQ. It seems probable that the co-ordinates of atom R are in error and that this is the explanation of the abnormal bond-lengths AR and RQ. However, if the co-ordinates of atom R are changed, the agreement between calculated and observed structure factors is adversely affected.

The investigation is being continued in an effort to determine the atomic co-ordinates more precisely. It is hoped to carry out three-dimensional calculations, and in addition more accurate methods of measuring the intensities are to be used. Full details of the crystallographic analysis will be published later.

Anisotropic Temperature Factors in Cubic Crystals

IN recent structure analyses of crystals it has been found impossible to obtain reliable atomic co-ordinates unless allowance is made for anisotropic thermal vibration of the individual atoms[1]. It has, of course, long been known that different atoms have different amplitudes of vibration even in cubic structures[2]. Weiss, DeMarco, Weremchuk, Corliss and Hastings[3] have recently reported that the Debye factors for the 222 and 400 reflexions from α-brass are different, and they have asked how this can be, since they interpret Ott's theory[4] as implying that the Debye factor for reflexions from a cubic crystal should be independent of crystallographic direction.

This is only true, however, if all atoms have similar thermal motions. It is not true in general: (1) if the amplitudes of vibration of different atoms are different; (2) if the amplitudes are anisotropic and the ellipsoids of thermal movement are differently orientated for crystallographically different types of atom.

Since $B^T = (\lambda^2/\sin^2\theta)\ln|F^R/F^T|$ (R = rest, T = given temperature), we may take $|F^R/F^T|$ as a measure of the Debye temperature factor. We shall assume that the mean parameters of the atoms are the same for the structure at rest or in therma motion, and then,

$$\frac{F^R(hkl)}{F^T(hkl)} = \frac{\Sigma f_r(hkl)\,.\,\exp 2\pi i(hx_r + ky_r + lz_r)}{\Sigma f_r(hkl)\,.\,\exp\{-B_r^{hkl}\sin^2\theta/\lambda^2 + 2\pi i\,(hx_r + ky_r + lz_r)\}}$$

Unless B_r^{hkl} is identical for all atoms, then in general this ratio will vary from one hkl to another. There will be different ratios even for different orders of reflexion from the same (hkl) and the ratio may sometimes be less than 1; that is, the structure factor may be greater at a high temperature than at a low one, and may change sign. There seems no reason, however, apart from extinction, dispersion and absorption effects, why the ratio $F^T(222)/F^T(400$ should vary with wave-length.

It is easy to demonstrate this variation of temperature factor by numerical examples. Suppose there are six atoms A at $\pm\,|\,x00,\ 0x0,\ 00x\,|$ and eight atoms B at $\pm\,|\,yyy,\ y\bar{y}\bar{y},\ \bar{y}y\bar{y},\ \bar{y}\bar{y}y\,|$ and that $f_A = f_B$ for all values of $\sin\theta/\lambda$.

(1) Let $[\sqrt{\overline{u_x^2}} = \sqrt{\overline{u_y^2}} = \sqrt{\overline{u_z^2}}]_A = \dfrac{a}{10}$ and $[\sqrt{\overline{u_x^2}} = \sqrt{\overline{u_y^2}} = \sqrt{\overline{u_z^2}}]_B = \dfrac{a}{20}$, where a is the lattice parameter. $(\sin\theta/\lambda) = 1/2a$ for 100, $1/a$ for 200, $\sqrt{3}/2a$ for 111. Suppose we take $x = 1/3$, $y = 1/6$

$$\frac{F^R(100)}{F^T(100)} = \frac{2(2 + \cos 2\pi x) + 8 \cos 2\pi y}{2(2 + \cos 2\pi x) . \exp(-2\pi^2/100) + 8 \cos 2\pi y . \exp(-2\pi^2/400)} = 1{\cdot}12$$

$$\frac{F^R(200)}{F^T(200)} = \frac{2(2 + \cos 4\pi x) + 8 \cos 4\pi y}{2(2 + \cos 4\pi x) . \exp(-8\pi^2/100) + 8 \cos 4\pi y . \exp(-8\pi^2/400)} = 0{\cdot}52$$

$$\frac{F^R(111)}{F^T(111)} = \frac{6 \cos 2\pi x + 8 \cos^3 2\pi y}{6 \cos 2\pi x . \exp(-6\pi^2/100) + 8 \cos^3 2\pi y . \exp(-6\pi^2/400)} = 2{\cdot}51$$

(2) Let atom A at $x00$ vibrate linearly along [100] with $\sqrt{\overline{u_x^2}} = a/10$, $\sqrt{\overline{u_y^2}} = \sqrt{\overline{u_z^2}} = 0$, and atom B at yyy vibrate linearly along [111] with $\sqrt{\overline{u^2}} = a/10$ (atom B at $y\bar{y}\bar{y}$ along $[1\bar{1}\bar{1}]$, etc.). Then if $x = 1/3$, $y = 1/6$:

$$\frac{F^R(100)}{F^T(100)} = \frac{2(2 + \cos 2\pi x) + 8 \cos 2\pi y}{2\{2 + \exp(-2\pi^2/100) . (\cos 2\pi x)\} + 8 \cos 2\pi y . \exp(-2\pi^2/300)} = 1{\cdot}01$$

$$\frac{F^R(200)}{F^T(200)} = \frac{2(2 + \cos 4\pi x) + 8 \cos 4\pi y}{2\{2 + \exp(-8\pi^2/100) (\cos 4\pi x)\} + 8 \cos 4\pi y . \exp(-8\pi^2/300)} = 2{\cdot}13$$

$$\frac{F^R(111)}{F^T(111)} = \frac{6 \cos 2\pi x + 8 \cos^3 2\pi y}{6 \cos 2\pi x . \exp(-2\pi^2/100) + 2 \cos 6\pi y . \exp(-6\pi^2/100) + 6 \cos 2\pi y . \exp(-2\pi^2/300)} = 2{\cdot}63$$

Mr. R. E. Gilbert, in this laboratory, has made ntensity measurements at different temperatures on hexamethylene tetramine, which are now being extended by Mrs. M. Canut, and these show the expected variation of Debye factor with direction. Measurements on urea also show a wide variation, even in the $\{hk0\}$ zone. An analysis of the latter results is now in course of publication in *Acta Crystallographica*.

Adsorption of Carbon Dioxide at −79° C. on High-Silica Sands

THE presence of an adsorptive layer on the surface of the grains of high-silica sands, postulated as a esult of determinations of the amount of methylene blue adsorbed from aqueous solution[1], has been confirmed by measurements of the adsorption of carbon dioxide at its vaporization temperature under atmospheric pressure. S-shaped isotherms were obtained, and the extent of the surface available to arbon dioxide molecules was calculated from the Brunauer–Emmett–Teller relationship[2]. These values were compared with the superficial surface areas determined by an air permeability method[3] or, for he finely powdered samples, by a light-extinction method[4]. The two sets of figures are given in Table 1 or three samples of silica and for four high-silica ands from the Lower Greensand exposure.

After washing away the intergranular clayey material, all the sands were found to be coated to a greater or lesser extent with compounds of iron or aluminium or both, and the presence of a crust of highly ferruginous matter accounted for the large surface area found by carbon dioxide adsorption on the red sand from Redhill However, after extraction with concentrated hydrochloric acid, the surface available to carbon dioxide molecules was still large compared with the superficial surface, and this was also true of the other sand samples after similar treatment, an observation which can only be explained by assuming that the silica surfaces were themselves considerably involuted. The ratio of the surface available to carbon dioxide to superficial surface was considerably less for the silica samples which had been subjected to crushing and grinding. It was further observed that these samples did not give rise to hysteresis effects in the gas adsorption experiments. (A sample of commercial silica gel gave a large hysteresis loop.)

The action of hydrochloric acid on three of the sand samples referred to in Table 1 appeared to result in the removal of basic impurities from narrow capillaries in the silica surfaces. Thus two of the samples showed hysteresis only after acid extraction, and two showed a significant increase in surface available to carbon dioxide. All the sands except that from the King's Lynn area took up less methylene blue from solution after acid extraction than previously. The Lynn sand showed no significant change in adsorptive capacity.

These observations seem to support the conclusion arrived at in a previous communication[1] that the silica surface uncovered by acid extraction is, in

Table 1

	Surface area (sq. cm./gm.) Superficial surface	By carbon dioxide adsorption
Quartz crystals	105	300
Milled sand	2,700*	4,800
Crushed flint	4,100*	17,000
Red sand ex Redhill, Surrey	121	4,100 (*H*)
do. extracted with conc. HCl	121	1,700
White sand ex Redhill	118	700
do. acid extracted	118	1,500 (*H*)
Yellow sand ex King's Lynn	134	3,400
do. acid extracted	137	3,200 (*H*)
Yellow sand ex Leighton Buzzard	61	4,100 (*H*)
do. acid extracted	61	4,900 (*H*)

* Measured by light extinction method. (*H*), isotherm showed hysteresis.

many sands, contained within narrow fissures and capillaries and is not, for example, accessible to molecules as large as those of methylene blue. At the same time, certain parts of the external silica surface are removed in the process of dissolution of neighbouring basic compounds, leading to a 'smoothing out'. This latter assumption was supported by the discovery that the strongly acid extracts from the sands contained silica in solution in significant quantities.

It is hoped that this work, which forms part of a general investigation of the surface properties of sands of industrial importance, will be more fully reported elsewhere.

Enrichment of Heavy Water by a Biological Method

In all methods for the enrichment of heavy water, the first stage is always very expensive, and a slightly enriched feed water could mean a lot in the price of the final product. Some biochemical processes, such as the photosynthesis of *Chlorella*[1], have been shown to give a small separation between light and heavy water. We have tried to investigate some further possibilities and measured the heavy-water content of water from some industrial biological and microbiological processes.

The greatest difficulty encountered in this type of problem is that industrial biological processes, for example, the growth of *Penicillum chrysogenum* in the production of penicillin, give a rather small volume reduction of the used water and can thus give only small enrichment factors. The most promising line of investigation seemed to us to be the first water percolation of barley in malt production, where the water uptake in the barley is a considerable fraction of the total water amount.

To ascertain the possibilities of the method, we have percolated barley with water in nine successive stages to get very great volume reductions. After every third percolation, the water was distilled to purify it from organic substances originating from the barley. Experiments were carried out with different proportions of barley and water, but otherwise under constant conditions as regards other relevant factors such as temperature, time of percolation, etc. The results are shown in Fig. 1 where enrichment factor α is shown as a function of the volume reduction ratio V_0/V. The diagram shows that there is a great difference in the enrichment proceeding in the various cases.

Lewis[2] has given the following relation for the separation factor s in the electrolysis of water:

$$\frac{dN_H}{N_H} = s \cdot \frac{dN_D}{N_D} \qquad (1$$

where N is the total number of isotopic nuclei taking part in the separation process. By introducing the initial volume V_0 and the end volume V in equation (1 we get, after some approximations:

$$s = \frac{\ln V_0/V}{\ln \frac{V_0}{V} - \ln \alpha}$$

The enrichment factor α is here defined as the rati between the molar concentrations of heavy wate in the volumes V and V_0 respectively. The straigh line that can be drawn in Fig. 1 for each series o successive percolations indicates that this formul can be applied also in our case. Stockholm tap wate has been assumed to have a heavy-water content o 0·015 per cent w/w. The following values for s hav been obtained:

Barley weight / Water weight	s
0·30	3·0
0·67	1·54
1·33	1·15

The isotope determinations have been made by means of infra-red spectrophotometry of the HDO absorption band[3] at 3·83μ. These measurements can be carried out with an accuracy of ± 0·003 per cen on the absolute D_2O percentage scale[4]. The observations of s were also confirmed by repeating a short series of three percolations with a wate containing 0·5 per cent heavy water and analysing for isotopic contents by means of precision pyknometry.

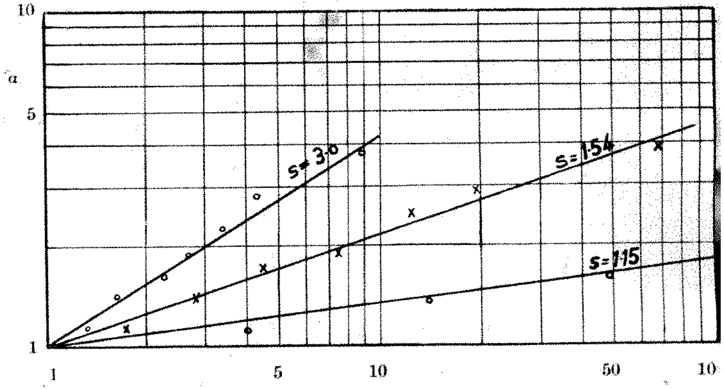

Fig. 1

The separation factors determined in this way seem surprisingly high for a biological method, and w cannot account for the variations in s with the barley–water ratio. One contributing factor may be the influence of the water contents in the barley.

Thermal Conductivity of Soil

THE flow of heat away from buried electric cables, team pipes, etc., is directly proportional to the onductivity of the surrounding soil. It follows that knowledge of soil conductivities is necessary to the ngineer. Unfortunately, there are almost as many alues of soil conductivity as there have been experimenters in this field. Austin[1] suggests that the lack f consistency has been inevitable due to the lack f standardization of apparatus and probably even nore so to the loose specification of the soil sample. The composition of soil varies enormously, and so lso does the water content and the tightness of the acking, yet these quantities must have an immediate earing upon the value of the conductivity.

Gemant[2] has made a very interesting calculation o find the thermal resistivity of soil. The oil is assumed to consist of uniformly acked spheres each of which touches six eighbouring spheres. The statement is made : If the spheres were to touch at a geometric oint only the resistivity of dry soil would e close to that of air . . ." I am unable o accept this statement, which amounts to saying hat the conductivity of a cube of air is not greatly nfluenced by the insertion into the cube of a spherical onductor.

However, the cube will now contain two phases, amely, the solid soil phase and the surrounding air hase. The conductances of these two phases must e added to yield the total conductance, and it will e shown that the conductivity is quite different om that of air.

Let O be the centre of a hemisphere of solid of adius a. At a height z above the XOY plane, that , at the section PQ, the radius of the solid phase is ven by $\sqrt{a^2 - z^2}$.

It follows that the area of the solid phase section $\pi(a^2 - z^2)$ and that the area of the air phase section $4a^2 - \pi(a^2 - z^2)$.

Consider now the thermal resistance of each phase turn, taking each time a 'slice' of thickness Δz :

$$\text{Thermal resistance of solid slice} = \frac{\Delta z}{k_s\,\pi(a^2 - z^2)}$$

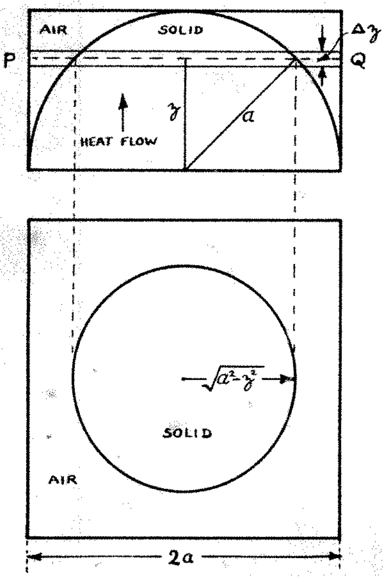

Fig. 1

$$\text{Thermal resistance of air slice} = \frac{\Delta z}{k_a\,\{4a^2 - \pi(a^2 - z^2)\}}$$

The thermal resistance of the two parallel phases is obtained by adding together the reciprocals of these two expressions and then taking the inverse of this sum. The resulting expression when integrated between the limits $z = 0$ and $z = a$ will yield the total resistance to heat flow of the half cube. Thus,

$$\text{thermal resistance is} \int_{z=0}^{z=a} \frac{\Delta z}{4k_a a^2 + \pi(a^2 - z^2)\,(k_s - k_a)}$$

The thermal resistivity is now obtained by equating the radius of the spherical particle to unity and by multiplying the integral by 4, the area of the base of the half cube.

Hence, thermal resistivity of the composite is :

$$\frac{4}{2\pi(k_s - k_a)\sqrt{1 + \dfrac{4k_a}{\pi(k_s - k_a)}}} \log \frac{\sqrt{1 + \dfrac{4k_a}{\pi(k_s - k_a)}} + 1}{\sqrt{1 + \dfrac{4k_a}{\pi(k_s - k_a)}} - 1}$$

in which $k_s > k_a$. Taking $k_s = 0{\cdot}010$ cal. cm.$^{-1}$ sec.$^{-1}$ deg. C.$^{-1}$ (suggested by Gemant) and $k_a = 0{\cdot}00006$ cal. cm.$^{-1}$ sec.$^{-1}$ deg. C.$^{-1}$ (Kaye and Laby give k for air at 0° C. $= 0{\cdot}577 \times 10^{-4}$) this formula gives a value for the resistivity of the air – solid composite equal to 400 cm.-deg. C./calorie.

The conductivity of dry soil is therefore 0·0025 cal. cm.$^{-1}$ sec.$^{-1}$ deg. C.$^{-1}$.

The observed conductivity of dry soil is, however, only one-third of this value (Jakob quotes a value of 0·0008) ; this wide discrepancy must be due to the initial assumption made both by Gemant and me, namely, that the particles are ideally packed spheres. I am aware that the heat flow is facilitated by convection and radiation in the air phase and that this will also have some influence on the thermal 'conductivity' of soil.

Flash Photolysis of Rhodopsin in the Retina

IT has long been suspected that the ability of rhodopsin to sensitize vertebrate retinal rods to visible light depends in some way upon the rapid and conspicuous fading which the purple photopigment undergoes when it is illuminated[1]. If so, some part of the bleaching process that is undergone by photochemically excited rhodopsin molecules must be very rapid, for vertebrate eyes respond very quickly to flashes of light. Indirect evidence for the existence of fast reactions in the bleaching of rhodopsin has been provided by Wald, Durell and St. George[2], who found that two successive unstable intermediates, lumi- and meta-rhodopsin, were formed when dry gelatin films or frozen solutions containing extracted rhodopsin were illuminated and examined spectrophotometrically. These authors suggested a scheme for the photochemical decomposition of rhodopsin

$$\text{Rhodopsin} \underset{(1)}{\overset{+h\nu}{\rightleftharpoons}} \textit{lumi}\text{-rhodopsin} \underset{(2)}{\overset{\text{(Thermal)}}{\rightleftharpoons}} \textit{meta}\text{-rhodopsin} \underset{(3)}{\overset{\text{(Thermal)}}{\rightleftharpoons}} \text{retinene-protein}$$

Fig. 1. Scheme proposed by Wald, Durell and St. George for the early stages in the photolysis of rhodopsin

shown in Fig. 1, in which they believed that all reactions except (3) would be fast enough *in vivo* to be able to play some part in the excitation of living rods.

A search for the reactions of Fig. 1 and measurement of their rates under conditions in which the eye usually functions seemed desirable, and this communication reports a study of the decay of a substance resembling meta-rhodopsin, produced by flash photolysis in intact visual rods.

Dark-adapted eyes were excised from freshly killed albino rabbits and quickly mounted in an air-saturated bath of neutral Locke's solution. A weak beam of steady monochromatic light was passed through the pupil to illuminate a small area of fundus. Light scattered back from the sclera through the rhodopsin-filled retina and the pupil was collected by an ophthalmoscopic arrangement and directed upon the cathode of a photomultiplier, the output of which was displayed oscillographically. At chosen intervals, bright 20-μsec. flashes from a xenon-filled discharge tube were focused upon the exterior surface of the translucent sclera overlying the area of retina being studied. The photochemical effects of the flashes upon the light-absorbing materials in the retina were determined by calculating the 'retinal density' D_r of the fundus from the oscillographic measurements of fundal reflectivity r by the formula $D_r = -\log_{10} r/r_0$, where r_0 is the reflectivity of a fully bleached fundus. Thus D_r increases with rising optical extinction of the light-absorbing layers of the retina.

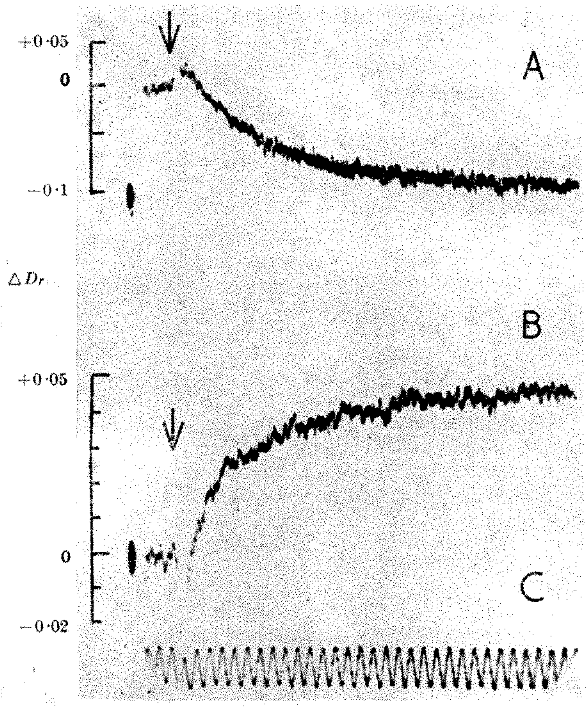

Fig. 2. (*A*) Reflectivity of a fundus at 486 mμ; flash at arrow. (*B*) Reflectivity of a fundus at 400 mμ; flash at arrow. Ordinates: Change in reflexion density ($\log_{10} r/r_0$). Abscissa: time. (*C*) Time calibration, 200/sec.

Curve *A* of Fig. 2 shows the effec of a flash upon the 'reflexion density of a dark-adapted fundus at 12° C measured in light of wave-length 486 mμ The oscillograph sweep began at th level corresponding to unbleached rhodopsin. At the arrow, a flash was delivered, with the result that the retinal density rose suddenly by a small amount and then fell exponentially to a lower level with a half-time of about 20 m.se Curve *B* shows an identical experiment except tha the measuring light is of wave-length 400 mμ. Her the flash produced no obvious immediate change except for a large electrical artefact ; but the retina density afterwards rose, again exponentially with half-time of 20 m.sec.

At higher temperatures, the rate of the exponentia reaction increases rapidly until at 26° C. it is hal complete in 1 m.sec. and becomes difficult to measur accurately. The rate-constant follows Arrhenius law with an apparent heat of activation of 27 kcal mole, so that at 37° C. it should have a half-time o about 120 μsec.

The identity of the substance which fades exponentially is not certain ; but its absorption spectrum has been estimated by measuring the immediat changes in retinal density produced by flashes in series of experiments using measuring lights o several wave-lengths. The results of such measurements are compatible with its being either lumi- o meta-rhodopsin. However, the exponential fadin reaction with the production of material whic absorbs strongly at 400 mμ is strongly suggestive o the conversion of meta-rhodopsin to retinene-protein

The earliest known response of the rabbit's eye t a flash of light is the electroretinogram, which has latency (in my measurements) of about 35 m.sec. a 26° C. and 20 m.sec. at 37° C. It seems clear, therefore, that the fast phases of the breakdown of excite rhodopsin molecules to retinene-protein are complet long before any electrical responses of the retina t a flash can be detected. Thus it is possible that an of the reactions of Fig. 1 may participate in th processes of visual excitation, though, of course, non of them need necessarily do so.

A detailed account of these experiments is preparation. The financial support of the U.S National Science Foundation and the Fulbrigh Commission is gratefully acknowledged.

Relationship between Air Concentration of Radioactive Fission Products and Fallout

Perhaps the simplest and most widely use methods for the evaluation of the long-range hazar due to atmospheric radioactivity and fallout are th air-filter and gummed-paper techniques, respectivel Since effects associated with meteorological factor especially rain, make it difficult to predict the pe formance of one method relative to the other, w believe that an experimental comparison which w made at the time of the 'Teapot' tests may be o interest.

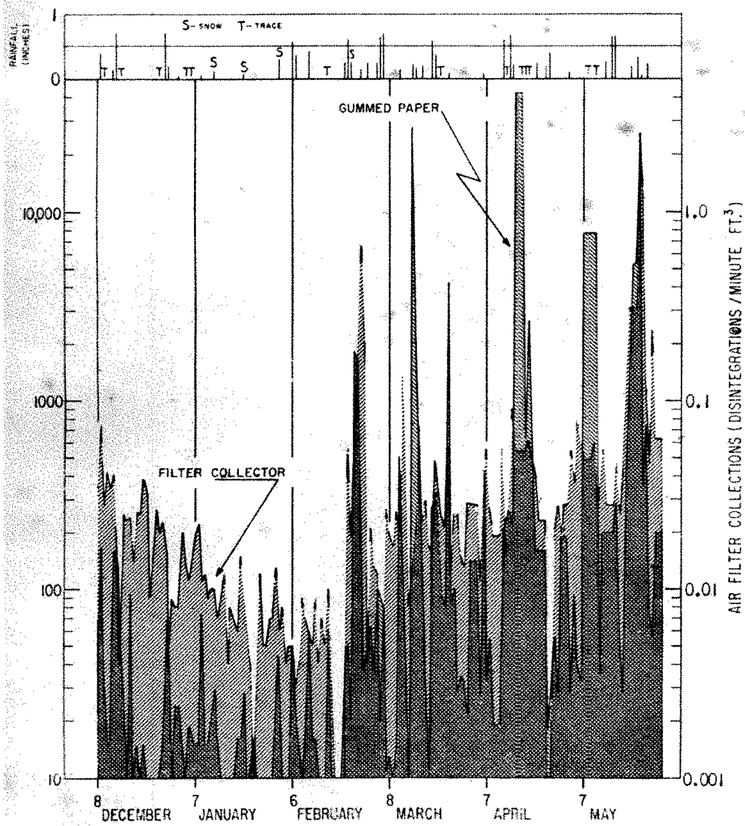

Fig. 1. Comparison of daily concentrations of fission products collected by gummed paper and air filter

The daily atmospheric concentration and fallout radioactivity due to fission products was measured Washington, D.C., during December 1954–May 55. Daily values of the fission product concentra-on per unit volume of air were obtained from filter llections (Blifford, I. H., Friedman, H., Lockhart, B., and Baus, R. A., to be published), using the parent rate of decay to distinguish between natural orium *B* and fission products. Simultaneous easurements of fallout were made using the standard mmed-paper methods developed by the Weather ureau and the Atomic Energy Commission[1]. The posited radioactivity per unit area was found from e counting-rate of the ignited residue of the gummed pers. In addition, weekly filter collections were sayed by allowing the short-lived natural products decay and then counting the ashed residue.

Results are shown in Fig. 1, where the right-hand dinate shows atmospheric concentration in dis-tegrations per min. per cu. ft. and the left-hand dinate shows daily deposited activity in dis-tegrations per min. per sq. ft. Rainfall is shown the top of the figure. The figure shows that the posited activity usually increases with rain or ow. This seems to be true for recent material from e 'Teapot' tests as well as for old fission products llected between December 1954 and February 22, 55.

The ratio of the fallout activity per unit area per y to the activity per unit volume has the dimen-ns of velocity. The expression 'rate of fallout' used in this discussion as a convenient means for mparing these quantities. As may be seen in Table 1, the observed rates of fallout varied from 0·7 to 400 × 10³ ft. per day. The average for these one-week collections over a five-month period was 43 × 10³ ft. per day. The fallout rates obtained from tabulation of the daily readings are shown in Table 2 for each month for the period December 1954–May 1955. In this case the average rate of fall was 2·7 × 10³ ft. per day for days without rain, and for rainy days, 30 × 10³ ft. per day. Non-homogeneity in the atmospheric concentration resulted in extremely high rates of fallout in some instances, when radioactivity apparently was rained out of high-level clouds from recent atomic tests. In other cases, rain caused a proportionately larger increase in the air concentration than in the fallout. It will be observed that fallout in a single week amounted to 65 per cent of the total for the whole period of the measurements.

There appears to be little basis for the correlation of individual daily measurements of the air concentration of atomic bomb debris and fallout of this material on the ground. The extent to which the average rates of fallout can be used to determine the long-term deposition is not clear. Undoubtedly, the distance from the tests at which measurements are made, particle size, the frequency of rainfall, efficiency of rainfall in washing the atmosphere, and height of rainfall are important factors. Although

Determination of the Rate of Initiation in Vinyl Polymerization

We have recently studied the polymerization of a number of vinyl monomers in essentially non-aqueous media in the presence of ferric chloride. There appear to be no data in the literature on the behaviour of such systems, and since the work provides important information about some aspects of the polymerization, we wish to report the main results here. In particular, they enable the rate of initiation to be determined simply and accurately.

When acrylonitrile in NN-dimethylformamide solution is polymerized with azobis*iso*butyronitrile as catalyst in the presence of hydrated ferric chloride, a ferrous salt is formed which may be estimated accurately by titration with ceric sulphate. It is found that for given monomer and catalyst concentrations the rate of formation of ferrous ion is practically independent of the initial ferric ion concentration over a wide range of values of the latter. This is shown by the results in Table 1, which refer to initial catalyst and monomer concentrations of $9 \cdot 63 \times 10^{-3}$ mole l.$^{-1}$ and $3 \cdot 76$ mole l.$^{-1}$ respectively at 60° C. In the absence of catalyst no ferrous ion can be detected, and no polymerization occurs. Further, ferrous salts have no effect on the polymerization. These results would follow if each chain started by the catalyst were terminated by reaction with ferric chloride, with formation of a ferrous salt. In this case it is easily shown that the rate of reaction is given by

$$-\frac{\mathrm{d}[M]}{\mathrm{d}t} = \frac{k_2}{k_5}\,\frac{I[M]}{[\mathrm{FeCl_3}]} \qquad (1)$$

where $[M]$ is the monomer concentration, I the rate of initiation and k_2, k_5 the velocity coefficients for chain growth and termination by ferric chloride respectively. By analogy with its behaviour in other organic solvents, ferric chloride is considered to exist in NN-dimethylformamide solution as $FeCl_3$ molecules. Fig. 1 shows that the results are in fact consistent with equation (1), a linear plot being obtained when the rate is plotted against $[M]/[FeCl_3]$ for constant concentration of catalyst. The degrees of polymerization obtained in these experiments were very much lower than those corresponding to bimolecular termination, indicating the virtual absence of the latter. In further accord with the proposed mechanism, we find that the rate of polymerizati at constant initial concentrations of monomer a ferric chloride shows first-order dependence on t catalyst concentration.

Table 1

$10^3[FeCl_3]$, initial (mole l.$^{-1}$)	$10^7\,\frac{\mathrm{d}[Fe^{++}]}{\mathrm{d}t}$ (mole l.$^{-1}$ sec.$^{-1}$)	$10^5 k_i$ (sec.$^{-1}$)
0·435	1·70	0·92
0·870	1·70	0·92
1·31	1·68	0·91
2·18	1·68	0·91
4·35	1·68	0·91

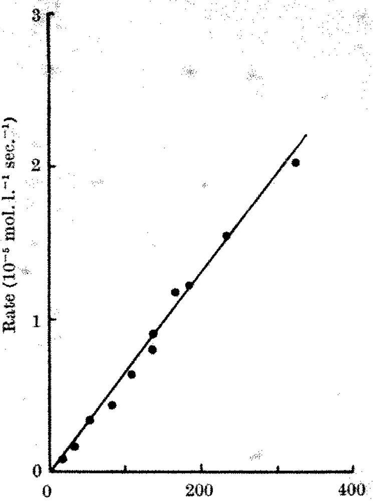

Fig. 1. Dependence of the rate of polymerization on concentratio of ferric chloride. Acrylonitrile 2·51 mole l.$^{-1}$ in NN-dimethylformamide, azobis*iso*butyronitrile $1 \cdot 14 \times 10^{-2}$ mole l.$^{-1}$; 60° C

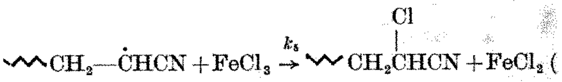
These results show that the reactions occurring m be summarized by the simple equation (2):



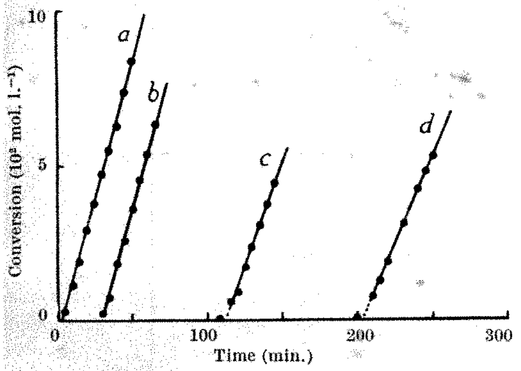
$$\sim\!\sim CH_2-\dot{C}HCN + FeCl_3 \xrightarrow{k_5} \sim\!\sim CH_2\overset{\overset{Cl}{|}}{C}HCN + FeCl_2\ ($$

Since the state of the ferric ion in these systems uncertain, the mechanism of this reaction is n clear; we believe, however, that an electron transf between the acrylonitrile radicals and ferric ion involved. It is interesting to compare these resul with those reported for aqueous systems. They a in the opposite sense to the observations on acryl nitrile mentioned by Dainton[1], but appear to resemb those on acrylamide and ferric salts[2]. Results recent described by Haines and Waters[3] for non-polyme radicals with structure analogous to that of pol acrylonitrile radicals are in qualitative agreeme with our experiments.

On the basis of this reaction scheme, the value $\mathrm{d}[Fe^{++}]/\mathrm{d}t$ gives at once the rate of initiation, a from this the rate constant k_i for the decompositi of the catalyst into useful radicals may be derive since $k_i = \frac{1}{2\bar{C}}\,\frac{\mathrm{d}[Fe^{++}]}{\mathrm{d}t}$, $\bar{C}$ being the mean conce tration of catalyst, which in the experiments Table 1 is only about 4 per cent different from t initial value. Values of k_i are given in Table 1.

The slope of the line in Fig. 1 is $6 \cdot 5 \times 10^{-8}$ mole l sec.$^{-1}$, and since $I\ (= 2k_i\bar{C})$ is known, we find th $k_2/k_5 = 0 \cdot 31$, and if $k_2 = 100$ mole^{-1} l. sec.$^{-1}$ $k_5 = 323$ mole^{-1} l. sec.$^{-1}$. It follows that if the molecular termination coefficient for acrylonitr radicals is 10^6 mole^{-1} l. sec.$^{-1}$, this type of terminati will be unimportant for concentrations of radicals l than about $1 \cdot 2 \times 10^{-7}$ mole l.$^{-1}$ for a concentrati of ferric chloride of 4×10^{-3} mole l.$^{-1}$. This is appr imately equal to the maximum concentration radicals in our experiments.

It might be expected that the rate of reaction would depend on the electron-donating properties the polymeric radicals. Acrylonitrile radicals a



'ig. 2. Induction periods in the polymerization of styrene 2·49 mole l.$^{-1}$) in methyl ethyl ketone at 60° C. Azobis*iso*butyro- ıtrile 6·92 × 10^{-3} mole l.$^{-1}$. Ferric chloride concentrations mole l.$^{-1}$): (*a*) 0, (*b*) 2·65 × 10^{-3}, (*c*) 7·95 × 10^{-3}, (*d*) 13·25 × 10^{-3}

ıong the least effective and styrene radicals among ɘ most effective in this respect. In agreement th this we find that while ferric salts are, as shown ove, retarders of the polymerization of acrylonitrile, ey are strong inhibitors of the catalysed poly- rization of styrene in solution in methyl ethyl tone or NN-dimethylformamide, and give rise to ll-defined induction periods. Some typical results given in Fig. 2. The length of the induction period directly proportional to the initial value of [Fe^{+++}] d inversely proportional to the concentration of talyst, and from it the rate of chain-starting may calculated. The values of k_i obtained are 74 × 10^{-5} sec.$^{-1}$ (methyl ethyl ketone) and 0·67 × $^{-5}$ sec.$^{-1}$ (NN-dimethylformamide).

If the rate constant for the decomposition of the talyst at 60° is taken as 1·2 × 10^{-5} sec.$^{-1}$, the iciency of initiation is 0·62 and 0·56 respectively the two solvents. This is in excellent agreement th results for styrene in benzene obtained by vington[5] using a tracer technique.

Nucleic Acid Content and Distribution of Chromosome Number in Original and Sublines of Two Mouse Ascites Tumours

Koprowski[1] has described the adaptation of the 3HED lymphosarcoma[2], an ascites tumour hal to *C3H* mice and to F_1 hybrids between the ginal strain and *A* or *DBA* mice, to a strain of iss mice. Two sublines, designated *C3H*+ and F_1, re obtained by injecting embryos of the *ICR* stitute for Cancer Research, Philadelphia, Pa.) iss mice *in utero* with blood of either *C3H* mice (*C3H* × *DBA*) F_1 hybrids, followed six to eight eks after birth by the intraperitoneal implantation with cells of the *6C3HED* ascites tumour. A third subline, No. 123, was established by injecting *ICR* mice in the embryonic stage directly with tumour cells followed by the intraperitoneal implantation into adult *ICR* mice of suspensions of the palpable tumours which developed in the subcutaneous tissue of the neck of mice that had been inoculated *in utero*.

More recently, Koprowski (unpublished results) has established—again employing the technique of implantation of tumour cells in embryos—a Swiss mouse (*ICR* strain)-adapted subline derived from the strain-specific *DBA* lymphoma ascites tumour.

As part of a programme to investigate biochemical differences resulting from this breaking of the strain barrier, the nucleic acids of the original *6C3HED* and *DBA* ascites tumours have been compared with those of the Swiss mouse-adapted sublines. *C3H* or F_1 mice bearing the original *6C3HED* ascites tumour, *DBA* mice bearing the original *DBA* lymphoma ascites tumour, and *ICR* mice bearing the derivative *6C3HED* or *DBA* sublines of ascites tumours, were killed on the seventh to tenth day after tumour implantation, and the ascitic fluids aspirated. Tumour cells were sedimented by centrifugation, washed several times in isotonic saline and finally suspended in isotonic saline and enumerated. Mixed nucleic acids were separated by the method of Schneider[3]. Aliquots of the cell suspensions were extracted with the following reagents in the order listed: cold 10 per cent trichloroacetic acid, cold ethanol, boiling 3 : 1 ethanol–ether, and hot 5 per cent trichloroacetic acid. Ribo- and deoxyribonucleic acids were estimated in aliquots of the hot 5 per cent trichloroacetic acid extracts by the orcinol and diphenylamine reactions respectively (see Table 1).

That marked changes occur in the quantity of cellular nucleic acids as a result of the adaptation of the strain-specific ascites tumours to the Swiss mouse is evident. Cells of the three derivative sublines of *6C3HED* showed an increase of 30–40 per cent in cellular deoxyribonucleic acid, and an increase of approximately 100 per cent in cellular ribonucleic acid over the original tumour line. Cells of the Swiss mouse-adapted subline of the *DBA* lymphoma ascites exhibited increases of approximately 100 and 300 per cent in the quantities of cellular deoxyribo- and ribo-nucleic acids respectively over the original line.

The results of a study of the distribution of chromosome number for the *6C3HED* ascites tumour (grown in *C3H* mice), the *DBA* lymphoma ascites tumour (grown in *DBA* mice), and for their Swiss mouse-adapted sublines are summarized in Table 1. The original *6C3HED* tumour exhibited a hypodiploid mode in chromosome number, whereas the original *DBA* ascites tumour was characterized by a diploid mode. Levan and Hauschka[4] have reported that both these tumours possess modal values at or near diploid. Of the three Swiss mouse-adapted sublines of the *6C3HED* ascites tumour, two (sublines F_1 and No. 123) revealed hyperdiploid modal values, whereas the third (subline *C3H*+) is characterized by a diploid mode in chromosome number. A tetraploid mode prevails in the *ICR* subline of the *DBA* lymphoma ascites tumour.

Leuchtenberger *et al.*[5] have shown that, for the Ehrlich ascites and *DBA* lymphoma ascites tumours, the estimation of nucleic acids in isolated nuclei by ultra-violet microspectrophotometry or by chemical analysis is in good agreement with the chromosome counts of Levan and Hauschka[4,6]. In general, the results presented here provide further evidence of a relationship between chromosome number and cellular deoxyribonucleic acid. Within each of the two groups studied (the *6C3HED* tumour with its three sublines and the *DBA* ascites tumour with its Swiss mouse-adapted subline), a striking correlation between chromosome number and cellular deoxyribonucleic acid is seen. The original *6C3HED* and *DBA* tumours, which contain essentially identical quantities of deoxyribonucleic acid, possess slightly different modal values.

* Standard error of the mean, calculated from $\sigma = \sqrt{\Sigma(x^2)/N}$, where x is the deviation from the mean, and N the number of estimati
performed.

Cell volumes have been estimated and the values are listed in Table 1. Although adaptation of each of the two strain-specific tumours to the Swiss mouse is accompanied by an increase in the size of the tumour cells, there appears to be no strict relationship between cell volume and the quantity of either of the cellular nucleic acids. In the case of the *6C3HED* sublines F_1 and No. 123, the increase in cell volume (32 and 41 per cent respectively) corresponds closely to the increase of 37 per cent in cellular deoxyribonucleic acid. However, the relationship does not hold for subline *C3H* +. In the second (*DBA*) group of tumours, a close correlation exists between the increase in cell volume (347 per cent) and the increase in ribonucleic acid (330 per cent) which followed adaptation to the *ICR* strain of Swiss mice.

The striking differences in susceptibility to virus infection between the main line *6C3HED* and its derivative tumours have been described[1]. It is tempting to speculate that the susceptibility of the *ICR*-adapted sublines to the oncolytic action of Mengo and Bunyamwera viruses is related to the marked alterations in cellular nucleic acids described. In any event, the system would appear to be an excellent one for studies of the requirements for virus reproduction, and for investigations into the relationships between cellular nucleic acids and the metabolic activities of the cells.

Immunological Studies with Protein Fractions isolated from Ehrlich Ascites Carcinoma Cells

THE oncolytic action of Bunyamwera virus on
cells of the Ehrlich ascites carcinoma has b
described by Koprowska and Koprowski[1], and
cytological and morphological changes induced
virus infection have been reported by Love, Kopro
ski and Cox[2]. During the past three years we ha
studied the effects of infection with Bunyamw
virus on many of the biochemical characteristics a
metabolic activities of Ehrlich ascites cells. Resu
will be reported elsewhere.

Attempts to demonstrate the immunologi
capacity of certain of the tumour cell proteins a
possible changes resulting from virus infection
the cells will be described here. Protein fractio
isolated both from uninfected and Bunyamwe
virus-infected Ehrlich ascites tumour cells, w
injected intravenously into rabbits, with the ho
that one antiserum or more would be produc
capable of interfering with the growth of the tumo
in mice. It is pertinent to mention here the wo
of Werder and co-workers[3] on the inactivation
mouse leukæmic cells by rabbit leukæmic tiss
antiserum, and of Nungester and Fisher[4], w
demonstrated the inhibition of lymphosarco
6C3HED by antibodies produced in the rabb
against a fraction isolated from the tumour.

Cells were obtained from Ehrlich ascites tumou
grown in Swiss mice. Ascitic fluids were collect
by aspiration from the peritoneal cavity on the nin
or tenth day of tumour growth; and virus infecti
of cells was accomplished by the intraperitone
injection, 72 hr. before harvest, of Bunyamwer
infected mouse brain. Cells were freed of erythr
cytes by washing in isotonic sodium chloride soluti
as described by McKee[5], after which they were tran
ferred to a mortar set in an alcohol – 'dry ice' ba
and ground to a fine, homogeneous powder.

Nuclei were separated from a suspension of t
ground cells in isotonic sodium chloride–0·001
sodium citrate solution of *p*H 7·0 by low-spe
centrifugation, washed several times in saline-citrat
and deoxyribonucleoprotein isolated therefrom by
technique derived from the methods of Stern *et a*
and Gajdusek[7]. In brief, this consisted of extracti
of the protein by prolonged shaking of the nucl
with distilled water, followed by its precipitati
from the extract at isotonic sodium chloride co
centration. Further purification was effected
subjecting the protein to several additional cycl
of dissolution in distilled water and precipitation
0·14 *M* sodium chloride concentration.

Ribonucleoprotein was isolated from the cyt
plasmic extract remaining after the separation of t

iclei according to the method of Mirsky and llister[8]. A third fraction, consisting of cytoplasmic otein and designated here 'soluble protein', was tained by the dialysis and lyophilization of the toplasmic extract after the removal of the nucleo-otein.

Antisera were prepared by the intravenous in-ction into rabbits of solutions of each of the follow-g: deoxyribonucleic acid, ribonucleic acid and luble protein isolated from uninfected Ehrlich lls, and the same fractions derived from virus-fected cells. Each rabbit received 2 ml. containing mgm. protein/ml. twice weekly for a total of ght injections. One week after the final injection, e rabbits were anæsthetized and bled by cardiac ncture. The sera were separated, sterilized by tration, and stored at – 30° C.

The antisera were tested for their ability to inhibit e growth of the Ehrlich ascites tumour in mice in e following manner. The cell concentration in a ol of ascitic fluid was adjusted to 80 million per ml. the addition of saline; 1-ml. aliquots of this ol were mixed with 3-ml. volumes of the various tisera or, as controls, with saline or normal rabbit rum. Ten mice were injected intraperitoneally with 25 ml. (5 million cells) of each of the resulting cell spensions. At intervals of 48 hr. thereafter, for a tal of three injections, each mouse received intra-ritoneally 0·25 ml. of the corresponding antiserum. The results from three separate experiments are mmarized in Table 1. In general, antisera against e nucleoprotein fractions exerted a strong inhibitory ect on the development of ascites in mice, while tiserum against the soluble-protein fraction was thout pronounced effect. The results also indicate at antisera against those nucleoproteins isolated m virus-infected cells are more effective in inhibit-g tumour growth than are those from uninfected lls. In the case of the deoxyribonucleoprotein, this servation was consistent in all three experiments. owever, with the ribonucleoprotein, there was an parent difference only in the first experiment per-rmed, in which seven mice died of solid tumours at developed at the site of injection, presumably a result of subcutaneous implantation of tumour lls.

Although an appreciable number of deaths occurred the groups of mice which received antisera against e nucleoproteins of uninfected Ehrlich cells, the ean survival times of the animals which died were nificantly increased; namely, 30–40 days as com-red to 12–13 days for control groups.

When the administration of antisera was withheld r periods of 24, 48 or 72 hr. following tumour implantation into mice, the development of ascites was not inhibited, and a marked increase in mean survival time was noted only in the case of a 24-hr. delay. However, if fewer than 5 million cells had been implanted, and more than 1·0 ml. (4 × 0·25 ml.) of antiserum afterwards injected, inhibition of tumour growth might well have been seen.

ble 1. INHIBITION OF THE EHRLICH CARCINOMA ASCITES TUMOUR MICE BY ANTISERA PRODUCED IN THE RABBIT AGAINST EHRLICH CELL PROTEIN FRACTIONS

plant: 5,000,000 cells, intraperitoneally. Controls: saline and normal rabbit serum; 100 per cent mortality with ascites

* Isolated from Ehrlich cells 72 hr. after infection with Bunyamwera us.

These preliminary observations clearly point the way to further investigations. It would be of interest to know the effects, if any, of antisera against the Ehrlich cell nucleoproteins on the growth of other ascites tumours in mice. The effects on the growth of various ascites tumours of mice of antisera against nucleoproteins isolated from a normal mouse tissue might also be studied. Finally, and perhaps most important, would be investigations designed to elucidate the mechanism whereby these antisera inhibit the growth of the Ehrlich ascites tumour. Work along these lines is in progress in our laboratory.

Tumour Growth-inhibitory Alkyl Sulphonates

IN the course of the preparation of various chloroethylamines which are potential tumour growth-inhibitors we have examined 2-chloroethyl methane-sulphonate (I, $X = Cl$; *CB* 1506) as a reagent for the direct conversion of an amino-group into a chloroethylamino-group under mild conditions. It occurred to us that amino-groups in biological systems might be chloroethylated *in vivo* by this compound. For this reason the methanesulphonate (I, $X = Cl$) was tested against a number of transplanted animal tumours.

(I) $CH_3SO_2OCH_2CH_2X$

2-Chloroethyl methanesulphonate is an effective inhibitor of the transplanted Walker rat carcinoma both in its solid and ascites form, either given as a single intraperitoneal injection of a solution in arachis oil (20 mgm./200 gm. rat) or by daily feeding of an aqueous solution (10 mgm./rat/day) for the duration of the experiment (thirteen days). A preliminary investigation of this substance by Dr. L. A. Elson indicates no significant depression of the bone marrow, as indicated by blood counts, at these effective doses (private communication). Dr. O. G. Fahmy and Mrs. M. J. Fahmy have examined the mutagenic action of 2-chloroethyl methane-sulphonate on *Drosophila melanogaster* and report that, while it is an effective agent, its mode of action appears to differ from that of the well-known biological alkylating agents such as the sulphur and nitrogen mustards, diepoxides, dimethanesulphonates, and polyethyleneimines (see following communication).

Cytotoxic activity is also shown by the fluorine analogue (I, X = F) when given by injection at the same dose level as (I, X = Cl) and by ethyl methanesulphonate (I, X = H). A striking feature is the greater efficiency of the latter compound (I, X = H) when administered orally in aqueous solution (20 mgm./rat/day) than by daily injection of the same solution.

2-Chloroethyl methanesulphonate was obtained as a colourless oil, b.p. 134–135°/14 mm., n_D^{17} 1·4571 (found C, 23·1; H, 4·6; S, 20·3; Cl, 22·0 per cent. $C_3H_7O_3SCl$ requires C, 22·7; H, 4·5; S, 20·3; Cl, 22·4 per cent) by the interaction of ethylene chlorohydrin and methanesulphonyl chloride in pyridine solution at 0°. 2-Fluoroethyl methanesulphonate, b.p. 130°/18 mm., n_D^{21} 1·4150 (found: C, 25·1; H, 4·8; S, 22·7 per cent. $C_3H_7O_3SF$ requires: C, 25·3; H, 4·9; S, 22·5 per cent), was similarly prepared.

Mutagenicity of 2-Chloroethyl Methanesulphonate in *Drosophila melanogaster*

Tumour-inhibitors belonging to the so-called alkylating agents (nitrogen mustards, diepoxides, dimethanesulphonates and polyethyleneimines) have been shown to be strong mutagens[1] when injected intra-abdominally into adult *Drosophila* males. This indicates that with these agents, the overall cell damage accompanying inhibition is, in part at least, due to action on the genetic material. The analysis of the nature of this genetic damage revealed some intricate differences in the mode of action of compounds belonging to different chemical series. These differences were most pronounced in relation to: (*a*) the cell stage predominantly affected, and (*b*) the proportion of the various mutations induced, particularly the ratio of sex-linked recessive visibles to lethals. In both these respects chloroethyl methanesulphonate (*CB* 1506) differs from all other potential alkylating agents so far investigated.

Chloroethyl methanesulphonate was administere by intra-abdominal injection in solution either arachis oil or in isotonic (0·4 per cent) saline. It w found that, for the same concentration of the co pound, the mutagenic activity is much higher (near ten-fold) in aqueous than in oil solutions, and accor ingly only aqueous solutions were used for the detaile genetic analysis. The optimal concentration range f mutagenesis work is 0·3 – 1·5 × 10^{-2} M and t average volume of solution injected per male 0·25 μl., thus making the dose-range 0·8–3·8 × 10 mole per male. The mutations scored were the se linked recessive lethals and visibles detected by t Müller-5 technique.

The cell stages of the male germ line showin maximal mutagenic response to chloroethyl methan sulphonate have been determined by the standar brood technique previously described[2]. Young mal (30 ± 5 hr. old) injected with moderate doses chemical mutagens (*L.D.* 50 or less), and whose pr geny was fractionated by repeated matings to fres virgin females every three days, were found t ejaculate sperm derived from post-meiotic germ cel within four broods (that is, twelve days after trea ment) and from meiotic and pre-meiotic stages i later broods. The results with the above techniqu for chloroethyl methanesulphonate are summarized i Table 1. It can be seen that the compound is pra tically ineffective on the mature sperm utilized i brood I, and very active on the early germ cel (mainly spermatogonia) utilized in the fifth–sevent broods. The data given for these later broods hav been corrected for clustering, on the basis of th frequency of identical visibles in each brood. Th selective mutagenic action of chloroethyl methan sulphonate on the pre-meiotic germ cells stands i sharp contrast to all other potential alkylating com pounds, which induce their maximal mutageni activity on post-meiotic germ cells, particularl spermatids undergoing nuclear condensation[2].

The most striking feature of the mutagenicity c chloroethyl methanesulphonate, however, is the ver high frequency of visible mutations it induces. Th ratio of visibles to lethals produced in the same sampl of treated X-chromosomes is roughly of the order c one visible to ten lethals for most of the other potentia alkylating compounds, except for the nitroge mustard derivatives of amino-acids where it is thre visibles to ten lethals[3]. The data presented in Table show that the overall ratio of visibles to lethals fo chloroethyl methanesulphonate is even higher, bein of the order of four visibles to ten lethals. For th germ cells most sensitive to the action of the com

reparation of Cell Suspensions from Rat Livers

Dulbecco and Vogt[1] have prepared suspensions of t liver cells by tryptic digestion in order to produce sue cultures from single cells. We thought that ch suspensions might be suitable for studies of llular respiration, but found that they contained o few intact cells and many mitochondria. The spiration of mitochondria was found to be unaffected en by concentrations of trypsin strong enough to se intact cells. An accidental observation suggested at a technique of mild acid digestion without added zyme might be effective. A solution similar to lbecco and Vogt's phosphate buffer saline[1] was ed. The phosphates were replaced by the equivalent ount of phosphoric acid and the solution brought the selected pH value with potassium hydroxide. e most acid solution used was at pH 2·3. This oduced the greatest yield of separated cells; but ey barely respired. More alkaline solutions yielded wer cells, but with increasing alkalinity the respiration-rate rose until with extraction at pH 4 a susnsion could be obtained with a respiration-rate of e value given by Krebs[2] for liver slices. In practice thought it best to use a medium of pH 5, which en mixed with the chopped tissue gives a pH value nearly 6.

The method finally employed is as follows. The er from a freshly killed six-week old rat is cut into mm. cubes with a battery of razor blades fixed gether, washed with phosphate buffer saline, pH 3, to remove most of the blood, and incubated th phosphate buffer saline, pH 5·0, for 10 min. at ° C. The medium is then poured off and 25 ml. of sh medium at the same pH value added. The sue is disrupted by being drawn into and out of inverted pipette about fifty times. Large particles e removed by filtration through glass wool. The lls are spun down at 1,800*g* for thirty seconds, and suspended in phosphate buffer saline, pH 7·3. The spension at this stage is contaminated with red lls, but these can be reduced in number by spinning 50*g* for 2 min. Repetition of this procedure will entually eliminate the contaminants.

Examination of wet films stained with 1 per cent utral red shows that most preparations contain dividual cells with only a few clumps containing to four cells. If the pipetting is not sufficiently gorous, the preparation shows large clumps and discarded. Permanent stained preparations can be ade on gelatine-coated slides and stained with hæmatoxylin and eosin (Fig. 1). In such preparations some of the cells tend to adhere to one another.

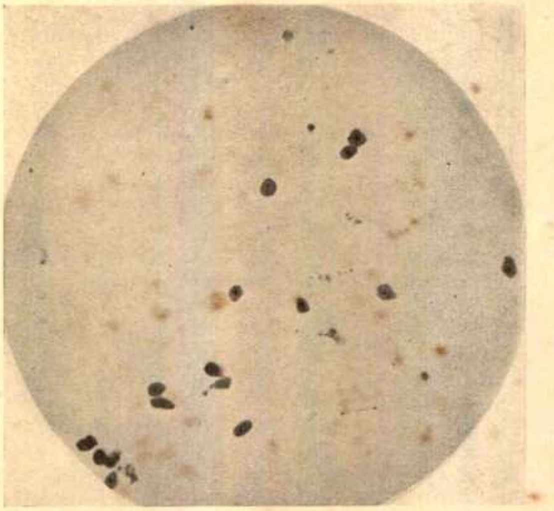

Fig. 1. Rat liver cells prepared as described, stained with hæmatoxylin and eosin. × 60

The Q_{O_2} in the presence of succinate is about -18 and is thus comparable to the values found by Krebs[2].

It is unlikely that such a weakly acid solution hydrolyses the cellular adhesive as does Hornsey's method[3]; it is more probable that some charge effect is involved.

We are indebted to Prof. A. Haddow, of the Chester Beatty Research Institute, for the supply of rat livers.

"The Metaphysics of Science"

In his essay on my Riddell Lectures in *Nature* of February 25, p. 369, Dr. C. K. Grant has quoted fairly and amply from what I have said; but some of his own contributions are, I am afraid, more likely to obscure than to clarify the problem. There are two basic questions.

The first concerns the nature of the laws of physics. Is everything that is logically possible also physically possible, or are the laws like those of statute books such as to exclude certain logical possibilities? To quote Russell's remark that "there is no logical absurdity in the idea that the Universe was created five minutes ago, complete with memories" does not help. The remark is obviously false. Had Russell said "complete with the illusion of memories" he would have avoided one error, but only one. "Logically possible" means, in scientific methodology, logically consistent with the complete body of scientific knowledge. In this sense, to give a striking recent example, Dirac found that a state of negative kinetic energy was logically possible. Answering the question posed above in the affirmative, he concluded that it was also physically possible, that is, not precluded by any law of the statute book kind. On this assumption he predicted that a state of negative kinetic energy would be observable in the form of the positive electron. This startling discovery justified the assumption made by Dirac that the laws of physics are not of the statute book kind. The important question is whether the same assumption can always be made.

The illustration taken from Dirac's work shows that the question belongs more to the methodology than to the metaphysics of science. The implication in Dr. Grant's quotation from Russell that it is easy to suggest what is logically possible leads one away from the question, while I want it to be faced. In fact, it is extremely difficult to know what is logically possible in the sense of logically consistent with the whole body of scientific knowledge. Mathematics is wholly concerned with discovering one part of just that. The important question is whether the same applies to physics, or whether some of the laws in physics preclude classes of events that would nevertheless be consistent with the whole body of knowledge. Had Dirac assumed that the laws of physics are of that restrictive kind, he might not have predicted the positive electron.

The second very basic question is about the laws of biology. If the laws of physics do not preclude any events that are logically possible, those of biology seem nevertheless to do so. For there is evidence that the laws of biology lead to specified order whereas the laws of physics do not. The label given by Dr. Grant to both kinds of law, namely, descriptive law, does not provide a means of testing this evidence for its validity. By giving one name to two things one cannot prove that they are the same thing. To dismiss the apparent differences between the laws of physics and those of biology as lightly as that is to do poor service to the methodology of science.

Reginald O. Kapp

"Gardole",
Stanhope Road,
Croydon.

Prof. Kapp's remarks have brought out one important respect in which we are at cross-purposes—and also in agreement. This concerns the notion of 'logical possibility'. Prof. Kapp contends that I have misunderstood his views on this matter; this may well be so, for it is now clear that he attaches to the phrase 'logical possibility' a somewhat unusual meaning, quite different from that which I have assigned to it. He asserts that " 'Logically possible' means, in scientific methodology, logically consistent with the complete body of scientific knowledge". Now Prof. Kapp, like anyone else, is entitled to attach any meaning he likes to any word or combination of words, and no one can gainsay him—except to point out that certain forms of words are misleading. I would like to persuade Prof. Kapp that his terminology is liable to lead to confusion.

I agree with Prof. Kapp, if I understand him rightly, that 'logically possible' is an expression that occurs not in accounts of scientific investigations or theories, but in what he calls the 'methodology of science' for which I should prefer the name 'philosophy of science'. This is a branch of logic, in a wide sense of that term. It therefore seems both relevant and important to make clear the generally accepted philosophical meaning of the phrase 'logically possibl This notion is applicable in two different ways.

(i) Application to an individual proposition, '*p* is logically necessary' means 'not-*p* is a se contradiction'. It is logically necessary that bachelo are unmarried because the denial of this propositic is self-contradictory—and this is what is meant l a logically impossible proposition. This is qui different from a false proposition; we do not fir out that no bachelors are married by conducting survey of bachelors; we can assert *a priori* that r bachelor can be married in virtue of the meanin or rules for the use of, 'bachelor'. It is clear from th that to say that a proposition is 'logically possibl is to say only that it is internally consistent; m quotation from Russell was designed to illustra this, although I quite agree with Prof. Kapp th Russell should have talked of 'the illusions memories'.

(ii) The notion of 'logical possibility' may als refer to the relation between one proposition or se of propositions and another set of propositions; he we are concerned with compatibility—or 'con possibility', to use Leibniz's phrase. Here again th issue is one that must be settled *a priori*, althoug as Prof. Kapp points out, it may be very difficu to do so. Prof. Kapp's account of the problem the relation between a certain hypothesis and th rest of the system is put in the form of the questic of whether physical laws "preclude classes events that would nevertheless be consistent wit the whole body of knowledge". This is to confus the vital distinction between an *a priori* and a empirical problem. If *p* and *q* are logically incon patible, we can assert *a priori* that both cannot l true; but which of them is true, if either, is a empirical issue. In Prof. Kapp's usage, if *p* is i compatible with the rest of the system, it is "logicall impossible"; this implies that it is unnecessary t investigate its empirical truth. But, of course, th question of its truth has not been touched an remains a problem. For Prof. Kapp to use th expression 'logically possible' in such a way that proposition can be logically impossible and yet tru is, to quote him, "likely to obscure . . . the problem' Although not explicitly stated, this conclusion entailed by the conception of 'logically possible' a meaning 'consistent with the rest of science'. Di coveries of fact (for example, the duck-billed platypu and of theory (for example, the heliocentric theory are often logically impossible in this sense, that i incompatible with the body of scientific knowledg

Prof. Kapp's use of the word 'preclude' shows tha he does not recognize the essential difference betwee descriptive and prescriptive laws; only the latte can be properly said to preclude anything.

In calling biological, as well as physical, law 'descriptive', I merely wished to direct attention t the fact that they possess an indicative or descripti character, as distinct from the laws of the land whic are imperative or coercive in form, and which may l properly said to 'make for order'. In applying th label to the laws of both biology and physics I di not, of course, try to prove that they are 'the sam thing', any more than one who says that both appl and peaches are fruit is trying to deny the differences.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, May 28

Royal Society of Arts (at John Adam Street, Adelphi, London, C.2), at 6 p.m.—Dr. Roger F. Tredgold: "Changes in Social sponsibilities". (Last of three Cantor Lectures on "Recent Studies Sociology".)

Tuesday, May 29

Vright–Fleming Institute of Microbiology (at St. Mary's spital Medical School, London, W.2), at 5 p.m.—Dr. R. E. O. liams: "The Numbers and Significance of Bacteria in Air"* mroth Wright Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at) p.m.—Sir Harold Spencer Jones, F.R.S.: "How We Get Our ie". (Lecture for Fourth Form Pupils.) (Further Lecture on 30.)

ociety of Instrument Technology (at Manson House, 26 Portd Place, London, W.1), at 6 p.m.—Annual General Meeting. Mr. G. Stanley and Mr. J. F. Brown: "Process Analytical Instruatation".

Tuesday, May 29—Friday, June 1

nstitution of Gas Engineers (in the Royal Festival Hall, South ik, London, S.E.1)—93rd Annual General Meeting.

Wednesday, May 30—Friday, June 1

nstitute of Petroleum, Hydrocarbon Research Group (at Institution of Electrical Engineers, Savoy Place, London, W.C.2) ymposium on "Vapour-Phase Chromatography".

Thursday, May 31

hysical Society, Low Temperature Group (in the Lecture atre of the Royal School of Mines, Prince Consort Road, London, .7), at 4 p.m.—Mr. N. R. Barber and Dr. G. G. Haselden: "The uefaction of Naturally Occurring Methane".

oyal Society (at Burlington House, Piccadilly, London, W.1), 4.30 p.m.—Sir Frederic Bartlett, F.R.S.: "Some Experiments ut Thinking" (Croonian Lecture).

niversity of London (at St. Thomas's Hospital Medical School, don, S.E.1), at 5 p.m.—Prof. E. Rothlin (Basle): "The Pharmlogical Basis of the Action of Lysergic Acid Diethylamide on in and Mind".*

Friday, June 1

Royal Institution (at 21 Albemarle Street, London, W.1), at .m.—Dr. A. Comfort: "The Biology of Old Age".

APPOINTMENTS VACANT

pplications are invited for the following appointments on or re the dates mentioned:

ssistant Lecturer in General and Physical Chemistry— Dean, Guy's Hospital Medical School, London Bridge, London, .1 (May 31).

ecturers (2) (with a good honours degree in electrical engineering, preferably completed a graduate apprenticeship, or with good istrial experience), one in Light and one in Heavy Electrical ineering—Head of the Department of Electrical Engineering, erial College, London, S.W.7 (May 31).

fficial Fellow and Lecturer in Physics—The Rector, Exeter lege, Oxford (May 31).

cientific Officer (with a good honours degree in botany or cultural botany) in the Seed Multiplication Section, Welsh nt Breeding Station—The Registrar, University College of Wales, rystwyth (May 31).

echnician in the new Department of Zoology, to take charge he laboratories, from August 1—The Registrar, University College wansea, Singleton Park, Swansea (May 31).

esearch Assistant (B.Sc. in chemistry or equivalent qualifica-), for investigations involving the application of isotope tracer hods to organic reactions—Prof. E A. Braude, Organic Chemistry oratories, Imperial College, London, S.W.7 (June 1).

ssistant (Grade B) in the Science Department, Croydon nical College, to teach chemistry—Chief Education Officer, ication Office, Katharine Street, Croydon (June 2).

iochemist Chemist, Senior grade (with a first- or second-class ours degree) in the Pathological Department—The Secretary, erpool Radium Institute, 1 Myrtle Street, Liverpool 7 (June 2).

ssistant Lecturer or Lecturer in Mechanical Engineering he Registrar, University College, Singleton Park, Swansea (June 5).

hair of Chemistry—The Registrar, University College, Singleton k, Swansea (June 5).

cientific Officer, Grade 1 (with a degree of high standard in nce or engineering with metallurgy as a major subject) in the ence Standards Laboratories, Department of Supply, Alexria, New South Wales, for research and investigational work in ical metallurgy—Senior Representative (A.P.57), Department of ply, Australia House, Strand, London, W.C.2 (June 7).

ssistant Lecturer (with a good degree in physics and preferably hing experience) in Physics—The Principal, Leeds College of nology, Cookridge Street, Leeds 2 (June 8)

Assistant in Genetics—Secretary of University Court, The University, Glasgow (June 9).

Assistant Lecturer in Philosophy—The Secretary, The University, Exeter (June 9).

Biochemist (suitably qualified graduate) in the Department of Hop Research for research work on the organic chemistry of the hop plant—The Registrar, Wye College, near Ashford, Kent (June 9).

Physicist, Experimental Officer grade (with at least H.S.C. (science) or equivalent), at a Ministry of Supply Experimental Establishment in Carmarthenshire to investigate problems arising in observation of behaviour of models under test, and introduce instruments (including optical and electronic) suitable for use under unusual conditions associated with these tests—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.166/6A (June 9).

Lecturer in Inorganic Chemistry—Prof. G. Wilkinson, Department of Chemistry, Imperial College, London, S.W.7 (June 10).

Lecturer and Assistant Lecturer (with special qualifications in organic chemistry) in Chemistry—The Registrar, The University, Manchester 13 (June 11)

Research Assistant (with a good honours degree in chemistry, biochemistry or physiology) in the Department of Surgery—The Registrar, The University, Manchester (June 14).

Senior Scientist (with high qualifications in physics or chemistry, research experience, and preferably a knowledge of coal science), at the National Coal Board's London Headquarters, to direct and co-ordinate investigational work on the physical and chemical properties of coal carried out by Coal Survey Laboratories, and to assist in the general direction of coal survey—The National Coal Board, Staff Department, Hobart House, London, S.W.1, quoting Ref. SS/280 (June 15).

Lecturer (with a special interest in the field of physical metallurgy, and preferably experience in the application of X-ray diffraction techniques to metallurgy) in Metallurgy—The Registrar, The University, Sheffield (June 16)

Soil Chemist (with an honours degree in science with inorganic or physical chemistry as a major subject) in the Division of Soils, Commonwealth Scientific and Industrial Research Organization, Canberra, A.C.T., Australia, to conduct investigations, as part of a research team, into the iron and aluminium phosphates in soil—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (June 23).

Assistant Lecturer (with a degree in science or in dairying) in Dairying—The Registrar, (Room 9, O.R.B.), The University, Reading (June 30).

Chair of Animal Husbandry and Preventive Veterinary Medicine—The Secretary of University Court, The University, Glasgow (June 30).

Research Fellow (with a Ph.D. degree and research experience in organic chemistry and ultra-violet spectroscopy), for work in connexion with the development of organic dye filters which will in the first place be used for astronomical purposes—The Registrar, College of Technology, Manchester 1 (June 30).

Fellow (preferably with practical experience in station seismology and geophysical prospecting) in the Department of Geophysics; and a Fellow in the Department of Nuclear Physics, Research School of Physical Sciences, Australian National University, to work with the 600 KeV. or 1·25 MeV. Cockcroft–Walton machine or with the 33 MeV. Electron Synchrotron—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (July 2).

Director of the Otago Museum, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (London and New Zealand, July 15).

Senior Lecturer or Lecturer (with a good honours degree in botany and specialist knowledge and research experience of plant pathology) in Plant Pathology at the Imperial College of Tropical Agriculture, Trinidad, B.W.I.—The Secretary, The Imperial College of Tropical Agriculture, 40 Norfolk Street, Strand, London, W.C.2 (August 1).

Biochemist, Basic grade (graduate), for research work in relation to steroids—Group Pathologist, Mental Hospitals' Group Laboratory, West Park Hospital, Epsom, Surrey.

Chemist or Physicist (with a first- or second-class honours degree or equivalent qualification, and preferably a knowledge of modern laboratory instrumentation techniques and experience in handling explosives), at a Ministry of Supply Research and Development Establishment, near Sevenoaks, Kent, for research on initiation of explosive systems and in application to Service stores—The Ministry of Labour and National Service Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.307/6A.

Demonstrator or Assistant Lecturer in Botany in the Department of Biological Sciences—The Registrar, Wye College, near Ashford, Kent.

Physicist (with a first- or second-class honours degree in physics, an interest in electronics and a liking for experimental work, and willing to development interests in classical and biological physics) with the Air Ministry at Farnborough, Hants, for research on problems connected with applications of physics to aviation medicine—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.190/6A.

Principal Scientific Officer and Senior Experimental Officer at the Ministry of Fuel and Power, London, for work in connexion with the development of windmills, hydraulic transport of coal, atmospheric pollution, industrial drying processes, oil burning, heat pumps, and the development of low grade fuels—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.180/6A.

Principal Scientific Officers, Senior Scientific Officers or Scientific Officers (with a first- or second-class honours degree and preferably research experience), for research on controlled thermonuclear reactions—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 2253/532/34.

Research Assistant (with, or candidate for, the B.Sc. (special chemistry) degree of the University of London) in Chemistry—The Registrar, Brighton Technical College, Brighton.

SCIENTIFIC OFFICER (with an honours degree in zoology, and preferably some knowledge or training in statistics) in the Edinburgh Laboratory of the Scottish Marine Biological Association, to join a team of biologists studying plankton ecology in relation to fisheries—The Officer-in-Charge, Oceanographic Laboratory, 78 Craighall Road, Edinburgh 6.

SOIL SCIENTIST, Scientific Officer or Senior Scientific Officer grade (with at least a second-class honours degree in agriculture or soil chemistry and two years postgraduate experience (three to appointment to the senior grade), preferably on plant nutrition problems), in the Research Branch of H.M. Oversea Civil Service, British Guiana, to study the nutriment supply to padi from soils under anaerobic conditions to determine how the yield may be maintained and increased economically by the use of fertilizers—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/30/01.

TECHNICAL OFFICER (with scientific training to at least higher school certificate standard, and preferably experience in meteorology) IN THE EAST AFRICA HIGH COMMISSION METEOROLOGICAL DEPARTMENT—The Crown Agents, 4 Millbank, London, S.W.1, quoting Ref: M3B/43104/NF.

TECHNICIAN (with experience in handling farm and/or laboratory animals) IN THE DEPARTMENT OF AGRICULTURE—The Secretary, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough.

Pickstone

NEW M.V.S.

(Mechanical Variable Speed)

LABORATORY STIRRER

with Controlled Speeds down to

2 REVS PER SECOND

This is a completely new design, using a compact and robust friction drive which gives a high torque at low speeds in either direction. Speed range is controllable anywhere between (forward) 2,000 r.p.m. (reverse) 1,000 r.p.m. and 120 r.p.m. Torque is independent of speed at moderate loads; the unit can be overloaded to a standstill without harm; the friction surface is renewable in a few seconds, cheaply. **This is the Stirrer numbers of our customers have asked for.**

£4.10.0 *includes packing and postage to anywhere in Gt. Britain.*

Other Stirrers, from £3 10s. Please write for full list of Pickstone Laboratory Equipment.

R. E. PICKSTONE LTD. 56/60 Islington Park Street, London, N.1. (CANonbury 6190)

A recent publication

THE HISTORY OF THE TELESCOPE

By HENRY C. KING,
Ph.D., F.R.A.S., F.B.O.A.

"Likely to become a classic. Dr. King has done enormous service. . . . I think there is no large telescope in the world that is not described, and most of them are illustrated with excellent photographs. The book is a remarkable piece of work, and in my view is the astronomy book of the year."

Dr. J. G. Porter in B.B.C. Review,
broadcast Feb. 24, 1956.

"This work fills a notable gap in astronomical literature. It is much more than a mere history of the evolution of the modern telescope . . . is one I can heartily commend. I am sure it will be warmly welcomed."

From Foreword by Sir Harold Spencer Jones, K.C.B., F.R.S.,
Late Astronomer Royal.

Magnificently printed. 456 pages. (10½ in. by 7½ in.) 196 splendid illustrations. Cloth binding. 50s. net.

HUMAN PROBLEMS OF INDUSTRIAL LEADERSHIP

THE brochure "New Developments in Industrial Leadership in Great Britain, the United States, rmany and France", which F. A. Heller has edited the Polytechnic Management Association*, is ed on four lectures and one discussion forum for ectors and senior executives, organized by the partment of Management Studies of the Poly- hnic, Regent Street, London. Even between the ding of the lectures in November 1954 and the blication of the brochure in December 1955, the portance of industrial leadership has been in- asingly recognized and, in particular, its bearing the introduction of new ideas into industry and causes of resistance to change and the most ective ways of overcoming that resistance. This ter problem was discussed more specifically by . J. F. Scott in his review of new aspects of manage- nt in the United States, although some of its olications were well indicated by Dr. J. A. C. own in surveying the British scene.

As Sir Geoffrey Vickers and Sir Walter Puckey nt out in their introduction, Dr. Brown's lecture s designed to introduce the series and to set the ole problem of industrial leadership in its broad ial as well as industrial context. None the less, challenges he threw out were taken up by the sequent lecturers, though Mr. F. A. Heller's survey ecent changes in industrial democracy in Germany minates especially the issues involved in joint nagement, and M. H. Hauck's review of modern nagement in private and nationalized industry in nce touches on the role of the trade unions and works committees. Both these lectures stress structural and legal aspects of leadership, as inst the psychological problems emphasized by Brown and Mr. Scott. In France and Germany, wever, there is the same realization as in Britain l the United States that much of the psychology l sociology of the nineteenth century must be arded, and that work will not be successful nomically unless it is also a satisfactory social ivity.

These last two papers describe some experiments ich have been made in the reorganization of great ustries in France and in Germany with the object changing the situation to which the people con- ned have to respond, and thus to encourage new itudes to change. Apart from Mr. Scott's paper, re is little reference to training or education in brochure; although the value of these activities stressed by Sir Geoffrey Vickers and Sir Walter key. The brochure is of value indeed chiefly for clear indication of the primary issues rather than setting forth precise action to be taken to over- e resistance to change or promote the spread of v ideas; and its importance has been accentu- d with the coming of automation to the fore as an urgent and leading issue. Moreover, Dr. Brown's contribution is of no less relevance to the issues of nationalization, which he shows, as it is practised in Britain, has created problems of human relations which are yet unsolved.

Dr. Brown begins by directing attention to the main implications for industrial leadership of the Hawthorne researches of the late Prof. Elton Mayo. The most important factor in industrial productivity is the feeling of the individual worker that his work has meaning and that he has a useful and essential part to play in society. In ordinary circumstances, money is one of the least effectual of incentives. People should and usually do, in fact, like their work, and changes in the physical conditions of work which involve no basic change in the common assumptions of management can lead to no fundamental improvement. Workers judge managers by what they do and by their assumed intentions. Management has to develop the social skills which lead to its acceptance by working groups, and, in particular, to the coincidence of the natural discipline of the working group and the formal discipline of management.

Accordingly, even if money were as effective an incentive as some people suppose, the study of human relations is essential in the Welfare State, where income tax largely removes the stimulus of increased wages and unemployment is no longer a real threat, and also because in modern mass production group co-ordination is of the first importance and the factory manager is concerned less with technical skills than with the co-ordination of human activities. To-day, authority can only come from mutual agreement between management and worker, as in fact the recent dispute over the reorganization and re-tooling of tractor production at the Standard Motor Company's works at Coventry seems to show. It is true, as Dr. Brown points out, that the study of human attitudes and relations can be carried to excess and the ultimate purpose of labour—the satisfaction of the consumer's demands and needs—overlooked; but the British industrial tradition is, on the whole, to resist change, and there is also a widespread suspicion of the idea that one can establish and put into practice a technique of human relations. With some exceptions, Dr. Brown suggests that British managements have paid lip service to Mayo's researches while fearing to put their implications into effect, or doing so only half-heartedly.

The fundamental issue, as Dr. Brown sees it, is the establishment of greater trust between the two sides of industry. Unless mutual trust exists, works councils, for example, are a waste of time; and this question of trust is the more important in view of the suspicion of technology which characterizes British scientific tradition—especially when concerned with human beings—and of the way in which our respect for the individual discourages any suggestion that he can be further understood by investigation or changed by new circumstances. As it is, Dr. Brown points out, while in Britain the workers are at present much better-off than anywhere else in Europe, there is more mutual suspicion between management and workers. Britain, in consequence, is more haunted by the past than many less progressive countries, and this is no less true of the nationalized industries than of private industry. In fact, Dr. Brown considers that whereas nationalization may have succeeded economically, in the human sense it has failed because it has not observed that ordinary individuals can only think in terms of people: the Trades Union Congress or the National Coal Board is without personal significance of any sort. It is probably true to say that the large privately-run concerns in Britain have shown a much greater tendency than nationalized industry to appreciate the dangers of over-centralization with its attendant bureaucracy, and have attempted to delegate authority to the local units.

---

* New Developments in Industrial Leadership in Great Britain, United States, Germany and France. Edited by Frank A. Heller. 75. (New Development Series, No. 1.) (London: Polytechnic agement Association, 1955.) 5s.

The two criteria by which we must judge the industrial working group, namely, its productivity, and the social and psychological satisfactions which it gives its members, are not in contradiction but rather go together. Dr. Brown argues that the only possible solution of our problem to-day is that of treating people as human beings, giving them responsibility and trusting them to respond. Status and function within the society to which a man belongs are the most important things to him. Mr. Scott's review of the way this solution is being worked out in the United States, and particularly the emergence in the past fifteen years of a new national attitude towards the study of management and the selection of managers, indicate the possibility of altering the pattern of human relationships and thus overcoming the traditional barrier which custom offers to technical change. No society, he remarks, can survive that cannot find ways of evolving managers who are at once technically suitable to new needs and at the same time acceptable to those whom they must lead.

Mr. Scott emphasizes two points that seem to be of particular importance in regard to industrial leadership in Britain to-day, and especially where, as in the issues raised by automation, technical aspects are interwoven with and dependent on human relations. First, Mr. Scott notes that the concept of productivity should be applied to management in its human aspects, so that we give due weight to preventing human problems arising and are not occupied solely in trying to solve them as they arise. Then, as a consequence of the greater interest in the study of management in the United States, more and more of the managers of to-morrow are being consciously selected and trained, and more and more of them are accepted. That is most important both from the point of view of recruiting leaders from all ranks of society on the basis only of ability, and in order to reduce the time-lag between technical discovery and production. Secondly, he emphasizes the importance of understanding. The details are important, but it is the spread of understanding that really counts and enables technical change to proceed smoothly and at an increasing rate. If we in Brita could learn to make greater use of social science a apply it in a less materialistic and mechanical w than has sometimes been done in the United Stat the difficulties in the introduction of automa methods might be much less formidable.

These four papers should stimulate that furth thought about industrial leadership and its functio which is needed as much on the trade union side on that of management. It is not always realiz how large are the demands for leadership made the trade unions themselves, though the implicatio have been brought out by Mr. John A. Mack in article contributed to the recent special issue of *T Political Quarterly* dealing with trade union problem In a wider context, however, the implications automation and of nuclear energy are well indicat by Dr. Alexander King in an article entitled "Scien and the Changing Face of Industry—the Soci Phase" in *Impact* of March 1956. Dr. King does n believe that the automatic factory is likely to becon common within the next decade, but considers th automatic working will extend sufficiently to cau considerable industrial strain and to necessitate t tackling of many difficult social and manageri problems.

Although Dr. King covers a much wider field tha automation, his article is an important contribution the discussion of the problems which this latest e tension of mechanization brings in its train, in that sets those problems in the context of technical chan generally and facilitates a clearer understanding what is involved in the changing pattern of indust under the influence of science. Technical innovati can no longer be considered apart from the hum factor, not merely from the point of view of technic education and the training of men and women in t skills required to operate new processes and to han new materials: regard must equally be had to t effects on society as well as on the pattern a location of industry itself. Dr. King gives inde clear warning that automation and nuclear power a not the only developments in which scientific di covery is changing the pattern of industry and human institutions. It may well be that on revolutionary developments in, for example, phot synthesis may enable the problem of population a food supply, particularly in the under-develop areas, to be solved.

The outstanding challenge to-day is, in fact, create the social and political institutions that w enable us to utilize the discoveries and techniqu which science and technology have put at our di posal. Such developments cannot be considered fro the point of view of a single scientific discipline even of a single technology or industry. Just as t first need was for co-operation between the vario natural sciences and engineering, so now the need increasingly for co-operation between different indu tries, between all sides of industry, and between t social as well as the physical scientists. Econom and social factors may determine the rate of progre much more than the technological factors; and whi at present the social sciences can, as Dr. Ki serves, do little more than delineate the problems, this third—the social—phase of industrial evolu- on, they may well play a more important part than e natural sciences or technology.

While the demands which nuclear power and tomation will make on management for wise adership are thus unmistakable, it should not be ought that that leadership is a responsibility of anagement or even of government alone. Tech- ologists will indeed, as Sir Walter Puckey remarks, ed to be more concerned with the effects of their ork on the men and women concerned, and managers give much more attention to human problems and the problems of organization involved in using achines more intensively. Neither, however, can their work effectively unless there is a wider preciation on all sides of what is involved—the nderstanding stressed by Mr. Scott.

Accordingly, it is the more welcome to find Mr. obert Edwards, member of Parliament for Bilston, eaking as a trade union general secretary at the ommittee stage of the Restrictive Trade Practices ll on May 3, and urging that we should not be raid of short-term redundancy with the develop- ent of increased production; but that on both des of industry, and on both sides of the House of ommons, we should face the social consequences of dundancy in the interest of the general standard of ving of the people and in the interests of an economy oving towards abundance. Further evidence of adiness to consider the needs of the community as whole rather than sectional needs in a particular dustry was forthcoming when the Minister of abour made his statement on automation on May 8. eplying to questions, Mr. Iain Macleod said that tomation is the latest and most novel form of chnological change, and is welcomed by the Govern- ent and responsible opinion on both sides of dustry as essential to the future efficiency of ritain. The problems of re-deployment of labour d of the introduction of new skills involved can be tisfactorily solved, he said, if the Government and th sides of industry work in close co-operation. It essential that firms contemplating the introduction automation should in their planning consider the fect on their workers from the beginning and bring em into early discussion. For its part, the Govern- ent accepts a continuing responsibility for main- ining the general level of demand and, besides the ovision for the extension of technical education ready announced, it would provide opportunities r training and would assist through its employment rvices workers who had to change their employ- ent. In the light of the imminent report from the epartment of Scientific and Industrial Research, he id he proposes to discuss the whole question with presentatives of the employers, trade unions and tionalized industries on the national joint advisory uncils, and, as appropriate, with other advisory dies. The Government is confident that if all con- rned play their part in this way, these new changes ll prove of immeasurable benefit to the nation.

These observations were welcomed by the Opposi- on in the House of Commons; and it was clear from the remarks both on May 8 and later, on May 10, when the Prime Minister was asked for a statement of policy, that both Government and Opposition welcome the development of this new technique but are both concerned as to its social and economic effects. Sir Anthony Eden, affirming the Government's complete support of a policy of full employment, said he is doubtful as to the expediency of consultation on the floor of the shop or factory rather than through the trade unions. He reiterated that a continual and steady improvement in our industrial techniques is necessary to preserve the competitive position of Britain in the world, to maintain full employment and to ensure a continuous rise in the standard of living. The Government hopes that industry will invest in the new types of machinery to the fullest possible extent, but simultaneously there must be joint consultations with industry at an early date so that the introduction of new methods may proceed without friction.

There is thus reason to hope that in spite of the dispute at Coventry, which has brought automation and its attendant problems to the notice of the general public, plans will be concerted in advance to reduce the difficulties and fears which many people understandably entertain about the consequences of technological change. Meanwhile, however, the Government's proposals for the expansion of technical education, and indeed the educational programme as a whole, should be scrutinized the more carefully with a view to their adequacy in providing not merely workers with the technical skill needed, but also citizens with the adaptability which an age of technological change demands of them as citizens as well as workers. Both technological and university education should likewise be examined for their ability to provide the leaders required not merely in industry but also in government and in trade unions. Nor must either management or trade unions delay in examining the appropriateness to modern conditions of their own practices, and the effectiveness of their present systems of recruiting and training leaders, and adapting policies or practices to new demands.

GUIDED MISSILES

Guidance

By Arthur S. Locke and collaborators. (Principles of Guided Missile Design Series. Edited by Grayson Merrill.) Pp. xvii+729. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1955.) 12.50 dollars; 90*s*. net.

DEVELOPMENTS in the theory, design and testing of guided missiles include some of the major contributions to military technology during recent years, and they are of considerable scientific interest. The nature of these developments, however, is such that security regulations have permitted only a limited amount of information to be published; and the proposed series of five books on the basic principles of the subject, of which this is the first volume, will constitute the first major published work.

The design of guided missiles involves many specialized fields. For example, the guidance of a missile introduces advanced problems in servomechanism theory, aerodynamics, radar, navigation and communications, and the application of analogue and digital computers. The present book covers the relevant principles of these subjects, albeit in an elementary, and occasionally disjointed, manner; this latter is to be expected since the work has been written by several authors, and the task of co-ordinating a subject with such a broad basis must have been extremely difficult.

The volume appears to have been written essentially for technical officers in the Armed Services, and civilian scientific personnel in defence and industrial laboratories engaged in the development of missiles. It will also provide a basic text-book for the more comprehensive postgraduate courses in guided missile technology which have been introduced at several Service colleges; and the specialist in any one of the topics mentioned above will find the book useful in providing a general introduction to the subject as a whole. On the other hand, it cannot be regarded as an authoritative text-book but rather as a reference work which will supplement the classified literature. The most important chapters are those dealing with terrestrial and celestial references; measurements of missile motion; detection and information gathering; missile guidance systems; and missile guidance bandwidth studies; because this material includes specialized topics which have not hitherto been described in the literature. In addition, the chapters on transmission of radio waves and servo-system theory have been well planned and presented, and they will give a newcomer excellent background material in these important subjects. Notwithstanding the brevity of the chapter on the missile airframe, the authors have included the derivation of the airframe transfer functions and their approximate representation in the form of Bode diagrams; this is a desirable step because it effectively bridges the gap between the essentially servo and the essentially aerodynamic aspects of the design problem. The historical introduction, outlining the development of anti-aircraft instruments and weapons and navigational systems, and the short chapters introducing tactical and economic considerations, will be of considerable interest to the military technologist.

In the attempt to cover so extensive a field in a single volume, several topics have been treated rather summarily, and in some cases the desirability of introducing them is questionable. The brief notes on mathematical methods, especially curve-fitting, probability theory, and correlation functions are inadequate and of little value, and various sections of the chapters on transmission of radio waves and on radar will be incomprehensible to readers having no previous knowledge of these subjects. Again, in the penultimate chapter, the brief notes on digital computers will tend to confuse rather than to clarify—it is not possible to describe a high-speed digital computer and to introduce the programming of the machine in four pages. But these are not major criticisms because, for the most part, the book is well written and gives a lucid account of the basic principles of missile guidance.

A noteworthy feature is the large number of well-conceived and excellently executed diagrams, which enhance and clarify a text that will be welcomed by all technologists interested in defence problems.

A. Porter

JUBILEE OF THE JOSIAH MACY, JR. FOUNDATION

The Josiah Macy, Jr., Foundation, 1930–1955

A Review of Activities. Pp. xii+174. (New York Josiah Macy, Jr., Foundation, 1955.)

TO medical research workers in Great Britain th Josiah Macy, Jr., Foundation is best known fc its admirably planned conferences and conferenc groups of investigators in different disciplines bu with common interests; the published reports c these meetings extend their value far beyond th small number of experts (usually twenty-five including "at least one from abroad") who are abl to attend them. The Foundation's policy of bringin together specialists in a variety of subjects and skill which may bear upon the topic chosen for discussio represents an enlightened interpretation of th founder's wishes that the trustees should pay specia attention to "integrating functions in medical science and medical education for which there seems to b particular need in our age of specialization and technical complexities". The "Transactions" of th successive meetings dealing with topics as various a administrative medicine, the adrenal cortex, live injury, neuropharmacology, problems of infancy an childhood, problems of ageing (appropriately th subject of longest study) and cybernetics, to nam only a selection, represent important if inevitabl rather diffuse contributions to the literature of thes subjects. It is interesting to note that the idea c arranging such serial meetings developed from th Foundation's initiative in organizing conferences o medical subjects of urgent military significanc during the Second World War, and from the desir then expressed by the groups of investigators attending the meetings concerned with rapidly developin research problems, such as wound healing and shock to renew their consultations at intervals over a perio of years.

The present book surveys the surprisingly wid range of activities of the Foundation during th quarter-century since it was established in 1930. I addition to the conference programme, these activitie have included support for certain marginal an somewhat speculative investigations which migh otherwise have languished, as well as for man subjects of more orthodox appeal. The review o these different activities is a little optimistic in it assessment of the studies aided (it is surprising, t say the least, for example, to find the whole story o the role of acetylcholine in the transmission of nerv impulses apparently attributed to one worker in th United States who has been assisted by the Foundation); but the Board of the Foundation is certainl to be congratulated upon the presentation of a ver creditable account of its stewardship.

The present value of the Foundation's endowmen exceeds 28 million dollars. In twenty-five years th Foundation has distributed more than 4,268,00 dollars as grants-in-aid (842 projects), and has spen more than 1,350,000 dollars on its conference programme and other operational activities. Naturally the greater part of its resources is expended withi the United States; but the report refers also to grant that have been made from time to time to investigators in Belgium, Canada, Denmark, France Germany and Great Britain, as well as to variou overseas conferences which have been subsidized An investigation within Britain currently bein assisted by the Foundation is the study by Dr. John Bowlby and others at the Child Guidance Department of the Tavistock Clinic, London, of the ffects upon personality development of the separation of young children from their mothers.

The guiding principle of the Foundation, in accordance with the expressed desire of Mrs. Walter Graeme Ladd, the founder, is to be interested in “the architecture of ideas”. This is a lofty aim, and here is no cause for wonder if some of the ideas thus assisted prove ephemeral. Taken as a whole, however, the Foundation's solid achievement in stimulating and co-ordinating good research work onstitutes an impressive memorial to Mrs. Ladd's father, after whom the benefaction is named.

F. H. K. Green

BRITISH UNIVERSITIES THROUGH AMERICAN EYES

Higher Learning in Britain

By Prof. George F. Kneller. Pp. xii+301. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1955.) 45*s.* net.

“IT is obvious from what has been revealed in this volume”, writes Prof. G. F. Kneller, “that the author sees a crisis, or better a critical situation, in the very intellectual substance of the writing which has appeared in the last few decades on university education *per se*.” This writing, which is a native diagnosis of the British university system, Prof. Kneller does not commend. After an intensive xamination of the literature on the “crisis”, he finds it “impoverished and rapid”, with “thinly-sown ideas”, “worn-out and threadbare documentation” and based on “trite and nugatory educational fundamentals”.

It is obvious that Prof. Kneller has little time for the rearguard skirmishers or the pessimists, for he regards their observations as “bickering”. As an optimist who sees that “values in abundance prevail everywhere”, he is obviously stimulated by the panorama of human interests and experiences in Britain that spring from the expansion of social, political and religious interests of the modern world. He sees in their interplay the very strength of the system. His sources of inspiration are basically cientific. A. N. Whitehead and (with reservations) J. D. Bernal are the stilts on which he lifts himself above despondency. His severest strictures are reserved for the purely ‘arts’ critic of our academic ociety. To him Sir Richard Livingstone is “uniformly vulnerable”; Dr. F. R. Leavis “verbally prolix”, reflecting the “constricted modes of the nineteenth entury”; Prof. M. V. C. Jeffreys “is not only unrealistic . . . but totally impractical” and Bruce Truscot “contradicts himself”. As for Sir Walter Moberly, Prof. Kneller writes, “It is rudely evident, o say the least, that Moberly did not succeed in defining the crisis in the university, but rather described one situation which might be said to involve a crisis”. For the bouts of academic fisticuffs that flared up around Sir Walter Moberly, Prof. Kneller provides a ringside commentary, recording ach blow with painstaking accuracy. He has, by so doing, made his point clear that the real crisis in the university is “in the very intellectual substance of the writing which has appeared in the last few decades on university education *per se*”.

Yet, though his sympathies are avowedly with the scientists and their claims, Prof. Kneller's ample bibliography and critical apparatus is singularly deficient on the scientific side. The *Economist* and *The Times Educational Supplement* are cited, but not *Nature*. Nor has he probed the influence of (among other bodies) the Advisory Committee on Scientific Policy, though he seems aware of its existence. Even when he does choose a scientist to adorn his story, he has to make him do the work of two. True, the present High Master of Manchester Grammar School probably can do this, but that seems no reason for giving him two separate identities in the index as “James, E. J. F., 232, 269 n. 12, 283” and “James, Eric, 92–3, 221, 257 n. 48, 261 n. 35, 283; quoted 93”. This is running against the Ockhamite canon: *essentia non sunt multiplicanda praeter necessitatem.* Evidently the necessity was too great.

W. H. G. Armytage

MEYRICK'S MICROLEPIDOPTERA

Catalogue of the Type Specimens of Microlepidoptera

In the British Museum (Natural History) described by Edward Meyrick. By J. F. Gates Clarke.

Vol. 1. Pp. vii+332+4 plates. 60*s.*

Vol. 2: Stenomidae, Xyloryctidae, Copromorphidae. Pp. iv+531 (263 plates). 120*s.*

(London: British Museum (Natural History), 1955.)

THE first of these volumes introduces the reader to the peculiar problems arising from the vast number of species of Microlepidoptera described by Edward Meyrick (1854–1938). It gives an alphabetical list of the 14,199 names he gave them, and indicates the location of the type specimens. The second volume consists mainly of illustrations of the types (or newly designated lectotypes) belonging to three families, and it supplements Meyrick's original verbal descriptions with photographs of the left wings, photomicrographs of skilfully mounted preparations of the genitalia, and sometimes photographs or drawings of other structural details.

The author expects that four more volumes will be needed to cover the Meyrick types in London; he will then have laid the foundations on which detailed revisions of the classification can begin. It is indeed a herculean task which Meyrick left unfinished. For over half a century he dominated the study of these small moths. Collections from many parts of the world were submitted to him for naming and description. He described new species very methodically, but had an almost fanatical objection to the designation of types. This complete faith in verbal descriptions implied a belief that they were sufficient to distinguish new species not only from those already known, but also from those yet to be discovered. In a period when the science of entomology was rapidly advancing, his methods remained unchanged. Moths were still mounted on brass pins—now often corroded—and inadequately labelled. Wing venation was the prime character on which he based his classification, and shape, colour and markings were used in specific diagnoses. The genitalia were seldom examined, with the result that important structural differences were unobserved, and occasionally the sex of specimens was mistaken. Gates Clarke claims that Meyrick's genus *Stenoma* is "one of the largest conglomerations of unrelated species ever brought under one name in the Lepidoptera". The illustrations of this genus in Vol. 2 show an astonishing diversity in the structures portrayed and will greatly help revisers of the group.

This pair of volumes is a landmark. It is a joint project of the United States Department of Agriculture, the Smithsonian Institution, and the British Museum (Natural History). The last-named authority is to be congratulated for the far-sighted decision to permit the dissection of so much type material. Would that comparable illustrated guides to the Linnaean and other great collections were available. The extension of this sort of work is vital to the understanding of the old descriptions of animals and plants, on which the stability of nomenclature depends.

Considering the quality of the production and the large number of excellent half-tone illustrations, the volumes are not expensive. Vol. 2 would have been more useful with an index and a table of contents, particularly since some species listed in Vol. 1 only under their original generic names are transferred to different genera in Vol. 2.

G. C. VARLEY

GENERAL THERMODYNAMICS

Thermodynamics from the Classic and Generalized Standpoints

By Dr. Joseph Louis Finck. Pp. xv+224. (New York: Bookman Associates, 1955.) 7.50 dollars.

THIS book presents ideas which the author has developed over a number of years in papers published principally in the *Journal of the Franklin Institute*. These ideas relate to a study of thermodynamics from what the author calls a generalized point of view, which concerns itself with the thermodynamics of metastable states and irreversible processes as well as with the stable states and reversible processes of classical thermodynamics.

The author admits that the transition from classical to his generalized thermodynamics involves concepts which his readers may be reluctant to accept and, in order to facilitate this transition, he gives in the first half of the book a presentation of the subject-matter of classical thermodynamics, in which emphasis is placed on the limitations of the classical approach. This section of the book suffers from a confused presentation of the concept of heat itself, illustrated by the frequent appearance of statements such as "in an actual case when a force is applied to a body, heat is involved". This is the more unfortunate in a book in which the main theme requires a clear appreciation of the difference between the definition of heat in classical thermodynamics, and the layman's concept of heat, which usually includes vague ideas arising from phenomena associated with friction and other dissipative effects. It is, indeed, with these energy dissipative effects that the remainder of the book is principally concerned.

In the second half of the book the author introduces his own concept of a 'complete' system, in which the total number of independent variables required to describe the state of the system completely includes those which are beyond the control of, and the existence and variations of which may be unknown to, the observer. By this means the author claims to show how 'incomplete' systems acquire dissipative properties such as viscosity and electrical resistance, and why in some cases these properties vanish at very low temperature. The phenomenon of catalysis i among the other subjects studied.

Although the reader is certain to find cause fo disagreement with the author in not a few places and although he is unlikely to conclude that the author's presentation of 'generalized thermodynamics' has answered his own questions to the degree of satisfaction which the author claims for himself the book is thought-provoking, and the autho invites comments from his readers.

R. W. HAYWOOD

NORTH AFRICAN PREHISTORY

Préhistoire de l'Afrique

Par Prof. Raymond Vaufrey. Tome 1: Le Maghreb (Publications de l'Institut des Hautes Études de Tunis, Vol. 4.) Pp. 458+60 plates. (Paris: Masson et Cie., 1955.) n.p.

PROF. RAYMOND VAUFREY has written a magnificent monograph, profusely illustrated on the prehistory of Algeria, Tunisia and Morocco the "Isle of Maghreb". So rich is it in documentation that one can confidently assert that it is neve likely to be entirely replaced. Prof. Vaufrey is a professor in the Institute of Human Palæontology Paris, and he has visited and worked in North Africa repeatedly. He has also absorbed the very considerable literature on the prehistory of the area which has not infrequently seen the light in obscure journal not easily obtainable.

After an introductory chapter and another on the history of research in the region, the Lower and Middle Palæolithic periods are considered. Account of the geological conditions and deposits are given and excellent half-tone and line diagrams illustrate the chapter. Next the main Capsian culture is deal with. Here Prof. Vaufrey seems to have accepted the conclusion that, in spite of the presence of some pigmy flints in the levels, a connexion with the Perigordian must be postulated. Incidentally, a regards the pigmies, it has been suggested that i these more southern latitudes softwood trees occurred in much greater numbers than in France during the Perigordian period. Microlithic industries are indicative of composite tools, and the best material fo hafts would surely be softwood. Pigmy flints, then in the main Capsian levels may merely mean that i these regions softwood was of commoner occurrence than it was farther north. A chapter on the late Capsian and another on the early Neolithic follow and the palæontology of the region is then considered. A chapter of general conclusions brings the book to an end.

As already remarked, the volume as a whole is a magnificent piece of work which will long remain the classic account of the prehistory of the "Isle o Maghreb". The drawings alone, some thousands o them from the pen of that acknowledged expert, the Abbé Bouyssonie, provide a corpus of information indispensable to the student. Prof. Vaufrey is to be congratulated on the production of such a magnificen contribution to the prehistory of Africa.

M. C. BURKITT

Antimetabolites and Cancer

Edited by Cornelius P. Rhoads. (A Symposium presented on December 28–29, 1953, at the Boston meeting of the American Association for the Advancement of Science.) Pp. vi+312. (Washington, D.C.: American Association for the Advancement of Science, 1955.) 5.75 dollars.

THE fact that the collection of papers given at this symposium in December 1953 provides a review of the field which is still, on the whole, up to date indicates the general high quality of the contributions.

Stimulating and informative papers by Hitchings, Burchenal, Mandel, Lansford and Shive, Parks and G. B. Brown review a great deal of the work which they and others have done on purine, pyrimidine and folic acid analogues as anti-metabolites, and describe what is known of their relation to the treatment of experimental and clinical malignant disease. Particularly significant in this connexion are papers by Skipper, and by Nichol and Welch, on the development of drug resistance following the administration of amethopterin and 8-azaguanine. Woolley ascribes the inhibition of growth of a spontaneous mouse tumour by analogues of 1 : 2-diamino-4 : 5-dimethylbenzene (a vitamin B_{12} precursor) to interference with the synthesis of B_{12} by the tumour. However, this hypothesis appears to be inconsistent with statements, made elsewhere in his paper, that transplanted tumours do not synthesize B_{12} but that, on the other hand, one of these tumours is better inhibited than the spontaneous tumour by the antimetabolites.

Informative papers on perhaps less well-known topics in the field are given by Nickell on plant tumours, by Totter on the effect of aminopterin on bone marrow, by Visser on the use of nucleoside and nucleotide analogues as anti-metabolites, by Nelson on fœtal abnormalities following the administration of anti-metabolites and by Weinhouse on the carbohydrate metabolism of tumour cells.

This book provides an excellent review by experts of the state of knowledge on the subject covered by the title.

G. M. TIMMIS

Mumps, Measles and Mosaics

A Study of Animal and Plant Viruses. By Dr. Kenneth M. Smith and Dr. Roy Markham. (New Naturalist Special Volume.) Pp. xii+160+20 plates. (London: William Collins, Sons and Co., Ltd., 1954.) 18*s*. net.

THIS is a serious study of animal and plant viruses. In common with other books in the "New Naturalist Series", it deals with its subject authoritatively, yet in a manner which is easily comprehensible to any reader with a reasonable background of general science. Drs. K. M. Smith and R. Markham explain the results of their researches, some of which are quite dramatic, in clear language, and they write compellingly of the work of others. Thus, the book deals with the gradual discovery of the very small size of viruses, of their unique methods of propagation, of the extraordinary relationship of many viruses with insects and "above all, of their border-line status between life and not life".

It is only twenty years since man saw a virus for the first time and only sixty years since the very existence of such things was first suspected. The authors describe how the electron microscope has shown us the shape and appearance of many of the viruses. A large part of the book deals with plant viruses, with particular reference to their importance in horticulture and agriculture; but there are also chapters on virus tumours and the control of virus diseases. Of particular interest is a section on everyday virus diseases, which should prove to be valuable to students of medicine, hygiene, public health and epizootics.

There are a useful glossary and a table giving methods of testing for common plant viruses. Many practical methods, useful for the university student, are given in the later part of the book. A good bibliography of references is appended to each chapter. The book is generously illustrated with electron micrographs and diagrams. The four colour-photographs, which show the effects of plant and animal viruses, are particularly effective.

W. L. SUMNER

Statistics of Therapeutic Trials

By Dr. G. Herdan. Pp. xvi+367. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1955.) 50*s*.

DR. G. HERDAN is primarily a statistician, being lecturer in statistics in the Faculty of Medicine in the University of Bristol. His book deals with a subject which has become very important in recent years and is the first book of its kind. It is intended for the use of physicians who wish to draw statistically valid conclusions from observations of the effects of therapy.

The book opens with a statement of fundamental principles which is not easy to read, but not essential to the understanding of what comes later. Diseases are divided into acute diseases, which are best studied by comparing one group of patients with another, and chronic diseases, in which it is sometimes possible to obtain information by calculating the regression coefficient of some measurement against time and comparing the results obtained in the same patient before, during, and after treatment. The appropriate statistical methods are described, and illustrative examples are worked out.

Special sections are devoted to studies of the treatment of pneumonia, poliomyelitis, scarlet fever, diphtheria, typhoid fever, and pneumococcal meningitis, as examples of acute diseases. The chronic diseases which are used as illustrations are cancer, pulmonary tuberculosis, rheumatoid arthritis, congestive heart failure, hypertension, diabetes and nephritis. Statistical studies of the treatment of all these diseases are discussed and it is surprising what a large number of the actual data come from the German literature. The book is attractively produced and could be read with profit by many physicians.

J. H. GADDUM

The Cytology and Life-History of Bacteria

By Dr. K. A. Bisset. Second edition. Pp. xii+164. (Edinburgh and London: E. and S. Livingstone, Ltd., 1955.) 25*s*. net.

UNTIL recently, bacteriology as a science has suffered from excessive parochialism, in that bacteria have been studied primarily because of their medical, industrial or agricultural importance. Dr. K. A. Bisset pointed out in the preface to his first edition that he was concerned to present the case "for regarding bacteria as living cells with the same structure and functions as other living cells", and in the second edition he incorporates evidence on this point which has been made available by technical advances during the past six years, such as the cutting of ultra-thin sections of bacteria for examination in the electron microscope.

The general plan of the book is unaltered, with sections on techniques, surface structures, the bacterial nucleus, reproduction and sexuality, life-cycles in bacteria, macroformations, and evolutionary relationships. The final chapter, on the genetics of bacteria, is unsatisfactorily short, and the subject would surely be better considered in relation to the chapters on nuclear structure and development. The number of illustrations has been considerably increased, and almost all of them are excellent and illustrate clearly the points at issue.

This monograph contains much that is stimulating, and it brings together a great deal of evidence which shows quite clearly that, despite their small size, bacteria are cells of considerable complexity. It is a pity that the author has in places adopted a rather over-enthusiastic style which detracts somewhat from the value of the book as a whole. C. S. CUMMINS

The Sun and its Influence

An Introduction to the Study of Solar–Terrestrial Relations. By Dr. M. A. Ellison. Pp. xii+235+9 plates. (London: Routledge and Kegan Paul. Ltd., 1955.) 21*s*. net.

THE subject of solar–terrestrial relationships is one that has not always been well served by authors. It is a pleasure to welcome in this book an addition to the literature which gives the verified facts and indicates their possible significance while eschewing speculation.

Dr. M. A. Ellison uses his first three chapters in describing the Sun: its radiation, the structure of its atmosphere, and the activity therein that is associated with the terrestrial effects to be described later. Solar reactions on the ionosphere, on the Earth's magnetic field, on radio propagation and on the polar aurora are then dealt with in some detail; and the last two chapters are concerned with the Sun's radio emission and the problem of cosmic rays. It is perhaps disappointing that no mention is made of the weather—if only to dispel some of the widely held beliefs connecting its vagaries with sunspots, for which the evidence is insufficient or even non-existent.

The author's approach presupposes no more than 'school-leaving physics', and within this limitation he has achieved his object of introducing to the reader a fascinating subject that covers many widely different fields. The expert will not, of course, find his own subject treated exhaustively; but the astronomer will turn with interest to the geophysical sections and the geophysicist to the astronomical chapters, and the layman with a wide general interest in science will read the whole book with pleasure and profit. A. HUNTER

Manual of Malayan Timbers

By H. E. Desch. Volume 2. (Malayan Forest Records—No. 15.) Pp. ix+329–762+plates 70–127. (Singapore: Malaya Publishing House, Ltd., 1954.) 15 Malayan dollars.

AS is explained in the foreword, this volume is the product of more than ordinary travail. Much of the original script was lost in 1942; but, after enlisting the support of Prof. Tanakadate, who was responsible for the publication of the "Foresters' Manual of Dipterocarps", by the late C. F. Symington, the author was enabled to rewrite most of it in Japanese prison camps between 1943 and 1945.

The format of the book follows that of Vol. 1, which was published in 1941. It is divided into sections, each dealing with one family, beginning with the Melastomaceae and proceeding alphabetically to the Winteraceae, with an additional section on the Coniferae. The scope of the work, originally intended to comprise only what was generally understood by commercial species, was eventually enlarged to contain any tree of which botanically authenticated material was available for study. The book includes a description of the wood of some four hundred different species, with details, wherever available, of weight, texture, durability, macroscopic features, mechanical, working and seasoning properties. amenability to preservative treatment, defects, importance and uses. Among the appendixes there is a most valuable bibliography listing 308 references.

The publication is well produced, and there are remarkably few printing errors. Some of the plates could have been better prepared and reproduced, but this is not the fault of the author. A revision of this manual may eventually become desirable, but this monumental compilation of data will remain a standard reference for many years to all who are interested in the timbers of South-East Asia.

Proceedings of the First International Symposium on Condensation Nuclei at Dublin, April 1955.

Edited by Mario Bossolasco. (*Geofisica Pura e Applicata*, Vol. 31; 1955/II.) Pp. 202. (Milan: Istituto Geofisico Italiano, 1955.) n.p.

THIS volume contains twenty-six papers dealing with techniques for measuring the concentration and size of Aitken nuclei ($5 \times 10^{-7} < r < 2 \times 10^{-5}$ cm.), their diffusion and coagulation, with the artificial production of these nuclei, and with related physiological studies.

A number of instruments based on the Nolan–Pollak counter, which measures nucleus concentrations by allowing them to become centres of condensation and measuring photo-electrically the extinction of a parallel-light beam by the fog, are described, but a novel modification by Rich which allows of size discrimination deserves special mention. R. Fürth contributes a valuable paper on the theory of diffusion and sedimentation of nuclei in a cylindrical container; this is used to good effect by Pollak and O'Connor in their experimental investigations of aerosol decay, from which they obtain information on the concentration, size and mass of the nuclei as a function of time. Two papers will be of particular interest to cloud physicists: Vittori describes the use of microchemical methods (Liesegang reactions) for the detection of atmospheric aerosols, especially chloride particles; Day presents some measurements of nucleus concentrations made over southern England and over the sea from an aircraft.

It is, perhaps, a little surprising that the main emphasis at this conference should have been upon the small Aitken nuclei when the larger aerosol particles are currently of greater meteorological interest. It is hoped that future conferences will pay more attention to the larger end of the spectrum and to such topics as the production, constitution and origin of atmospheric aerosol. However, this first meeting has produced a valuable set of papers, in the preparation and publication of which the organizers have achieved a high standard.

B. J. MASON

THE PERKIN JUBILEE CELEBRATIONS

THE discovery of mauve by W. H. Perkin in 1856 had consequences reaching so far beyond the dye-making and dye-using industries that, while the celebration in London of the centenary was fittingly initiated by the Society of Dyers and Colourists, the celebration was appropriately sponsored also by the Royal Society, the Chemical Society, the Society of Chemical Industry, the Royal Institute of Chemistry and the Association of British Chemical Manufacturers. The proceedings opened on May 7 with a reception to the principal overseas guests at the Tallow Chandlers' Hall, and on the following morning the Perkin Exhibition at the Science Museum, South Kensington, was opened by Dr. R. P. Linstead, to whose part in establishing the structure of the phthalocyanines Sir Robert Robinson, who presided, paid a happy tribute. Dr. Linstead, before declaring the exhibition open, made two points. Emphasizing Perkin's youth and initiative, he referred to the danger of so over-organizing research that initiative and enterprise are discouraged if not suppressed. Secondly, he stressed the remarkable speed with which Perkin's discovery was brought to production, and remarked that this also has its meaning for us to-day. Besides illustrating the attendant circumstances of the discovery and the subsequent development of the industry, the exhibition included a number of interesting letters from contemporaries of Perkin.

The main feature of the celebration was a series of four lectures which dealt with different aspects of Perkin's discovery and its results. In the first of these, Prof. John Read surveyed the life and work of Perkin, presenting a vivid picture of the scientific and technical setting in which the discovery was made, and bringing out above all the human qualities of the young chemist who made it, the difficulties which he had to overcome and the magnitude of his pioneering effort, not only in manufacture but also in the application of the new colouring matter. Moreover, Prof. Read was careful to portray not merely Perkin as the discoverer and manufacturer of mauve but also his subsequent career as a research chemist, in the course of which his synthesis of coumarin was a step towards the beginning of the synthetic perfume industry, as the reaction known by his name later permitted von Baeyer's synthesis of indigo; Perkin's deep interest in religion and in music was also emphasized.

In the second lecture, on May 9, Mr. Clifford Paine, development director of Imperial Chemical Industries, Ltd., drew on his forty years experience in the dyestuffs industry to give a masterly account of the development of the dyestuffs industry since Perkin's day, in which the principal features were indicated in a way readily intelligible even to a non-technical audience. Mr. Paine noted the way in which the industry has turned full circle in that, while Perkin's mauve came from an unsuccessful attempt to prepare quinine, the discovery of paludrine at Blackley has rendered the synthesis of quinine of no pharmaceutical importance. To recapitulate the outstanding advances of successive decades would not do justice to an address which abounded in touches, as in the references to the level of research expenditure and the difficulties over laboratory glassware in the First World War, which were obviously based on Mr. Paine's personal experience. A moving moment in the celebrations was when Dr. Herbert Levinstein, who had been managing director of Levinstein, Ltd., when Mr. Paine joined the firm, and was the sole living link with the jubilee celebrations of 1906, rose to express the thanks of the audience.

Mr. Paine himself presided when, on the afternoon of May 9, Mr. J. G. Evans, technical director of the Bradford Dyers Association, read a paper on "The Tinctorial Arts To-day". Mr. Paine reminded the audience that a quarter of a century earlier Mr. Evans had assisted Prof. H. E. Armstrong in his lecture "At the Sign of the Hexagon" in the same lecture theatre of the Royal Institution, and on asking for guidance as to the order of the demonstrations had been instructed to "Use your intelligence, man". Mr. Evans began by reading Perkin's original patent and, enlarging on the dyeing materials at the disposal of the dyer in Perkin's day and the available techniques, stressed the importance of Perkin's contributions in the application of mauve and allied dyestuffs. These contributions were even more important than the discovery of mauve itself and have remained in use to-day long after mauve has been superseded. Mr. Evans indicated the way in which new dyestuffs and changing requirements for fastness have set new problems for the dyer, and referred particularly to the problems arising from the advent of new fibres and new dyestuffs. To meet the demand for increased productivity, continuous methods of dyeing are being introduced, and Mr. Evans mentioned the limits within which such methods are applicable. The vote of thanks was moved by Mr. C. M. Whittaker, who, like Mr. Evans, was originally engaged on the dyemaking side of the industry before becoming connected with the dyers, and who took the opportunity to stress the part which co-operation between the makers and users had played in the renaissance of the British dyestuffs industry.

Sir Alexander Todd's lecture on "The Development of Organic Chemistry since Perkin's Discovery", delivered on May 10, drew the smallest audience; but his fascinating survey was fully as intelligible to a non-technical audience as the three preceding lectures. Enlarging on the position of organic chemistry at the time of Perkin's discovery, only four years after Frankland's introduction of the idea of valency had given organic chemistry, or the chemistry of carbon compounds, a chance to grow, Sir Alexander gave his own view of the few simple conceptions which made the modern edifice of organic chemistry possible: Kekulé and Couper's independent introduction of the idea of the combining capacity of quadrivalent carbon atoms; Butlerow's postulate that structure determines properties; Kekulé's benzene ring structure; and the ideas of van 't Hoff and Le Bel regarding stereoisomerism, with Thiele's theory of partial valency. In the past fifty years, the major influences on the development of organic chemistry have come from physics, and in the last fifteen years dynamic aspects especially have been to the fore.

Sir Alexander emphasized the close connexion, in the latter half of the nineteenth century, of the development of organic chemistry with the rise of chemical industry, and showed how in this field science and industry have worked hand in hand. He believes that the future of industrial organic chemistry is assured, though he foresees no radical departures. While in the latter half of the nineteenth century there were few chemists working on the chemistry of living matter, in the past fifty years there has been a striking return to the original objectives of organic chemistry, and, thanks largely to new experimental techniques, academic organic chemistry may well be on the threshold of striking developments, especially in the natural products field. We now have the necessary knowledge and technique to embark on the study of such problems as the relation between chemical structure and biological action and the mechanism of biological action with reasonable hope of success. Organic chemistry, without doing the job of biology or becoming a mere handmaid to biochemistry, is likely to continue to be concerned, as was Perkin, with the natural products.

The form of the centenary celebrations thus differed considerably from that of the jubilee celebrations in 1906. The presence of Dr. Levinstein provided a living link, as already noted, and the reception at Guildhall on May 8 and the banquet on May 9 gave some measure of resemblance, and especially in the international character of the gathering. Lord Salisbury, in his tribute to Perkin, stressed appropriately the importance to Britain of being alert to make the fullest and speediest use of existing knowledge, as well as being active in research, and Mr. Paine, in proposing the toast of the guests, contrived a happy reference to the British industry's Perkin medallist, the late Mr. J. Baddiley.

Nevertheless, the celebrations, for all the excellence of the lectures, left a certain sense of disappointment or frustration, and this bears on a further feature which the jubilee and centenary celebrations have in common. In 1906 a Perkin Research Fund was established and is administered by the Chemical Society. In connexion with the centenary celebrations, it is hoped to raise £100,000 to found Perkin Centenary Scholarships designed "to promote, advance and encourage technical education in relation to all aspects of the fabrication or application of colouring matters". The proposal is timely, and Lord Salisbury's speech was well calculated to commend it. Not only was that speech, however, unnoticed in the daily Press, but also the whole opportunity which the centenary celebration offered of commending a career in technology to youth was ignored. That opportunity is not likely to recur speedily, and the excellence of the lectures testifies to what was missed. It is easy to suggest reasons for the comparative seniority of those present, though equally easy to suggest ways in which youth might have been encouraged to attend to receive inspiration. But the contrast between the treatment by the Press of the celebrations in 1906 with those of 1956 suggests some neglect of responsibility. *The Times* could find nearly three columns for the proceedings at the Royal Institution and the banquet in 1906; but in 1956 neither lectures nor the Lord President of the Council received a line. The *Manchester Guardian* published an admirable supplement on the centenary, but did not report the celebrations, and only in *The Times* was there a brief note of the exhibition at the Science Museum. Yet the fine-chemical industry is of even greater significance now than it was in 1906. Without the imaginative co-operation of the Press, it seems idle to hope that youth can be brought to realize the opportunities which technology offers, or public support and understanding secured for the expansion of technical and technological education that Britain's economic future demands.

RESEARCH ON THE HUMID TROPICS

THE UNESCO PROGRAMME

IN the humid tropical regions, as in other parts of the world, the development of the land to meet the needs of rapidly growing human populations and the ultimate attainment of a satisfactory equilibrium between man and his environment, depends on scientific research. The need for fundamental research is especially great in these regions, partly because scientific activity has been centred mainly in the temperate zones and partly because so much of the research which has been done in the tropics has been applied and short-term in its aims. To-day the need for research on the problems peculiar to the humid tropics is particularly urgent, not only because there as elsewhere populations are rapidly outgrowing their food supplies, but also because at a time when large areas of tropical Africa and Asia are passing from a Colonial to a more or less independent status, countries which formerly depended on Colonial powers for the staffing and impetus of their research programmes will in future try to depend wholly or to a large extent on their own resources. For this reason, and because a great many of the scientific problems of these regions are world-wide or at least common to more than one country, the help of United Nations specialized agencies such as the World Health Organization, the Food and Agriculture Organization and the United Nations Educational, Scientific and Cultural Organization is both timely and necessary. Unless stimulus and support are given to fundamental research in the humid tropics by powerful international bodies, research in such countries is likely, for political and economic reasons, to be even more narrowly 'applied' and *ad hoc* in the future than it has tended to be in the past.

It was considerations of this sort which prompted the proposal that Unesco should develop a programme to assist research in the humid tropical regions parallel and complementary to the programme which it initiated in 1951 for research on the arid regions. The proposal was approved at the eighth session of the General Conference of Unesco held at Montevideo in November 1954, and in accordance with the resolutions of the Conference a preparatory meeting of specialists in humid tropics research was held at Kandy in Ceylon during March 22–24 last. Since many of the most urgent problems of the humid tropics concern deforestation, erosion and land-use generally (and are therefore in the broadest sense of the word ecological), it was thought appropriate that the preparatory meeting should be preceded by a symposium on "The Study of Tropical Vegetation". This took place at Kandy and was held during March 19–21. The preparatory meeting was attended by delegates from Brazil, Ceylon, France, Holland, India, Indonesia, Pakistan, the Philippines, the United Kingdom and the United States, as well as by representatives of the specialized agencies of the United Nations (Food and Agriculture Organization, World Health Organization and World Meteorological Organization), of several international scientific unions and associations and of the Unesco secretariat. Several members of the preparatory meeting also took part in the symposium, but not all the twenty-one members who presented papers to the latter attended the meeting.

At the symposium twenty-two papers on tropical vegetation were presented, and the term 'humid tropics' was so widely interpreted that some papers dealt with regions of relatively dry climate such as Madhya Pradesh in India for which 'seasonal' might be a better description than 'humid'. Since the contributions to the symposium will be published by Unesco (it is hoped later this year), it is unnecessary to summarize them here; but it may be noted that the subjects covered ranged from vegetation mapping and the application of aerial photography to the survey of tropical plant communities to the cytogenetical analysis of the forest flora of south-eastern Asia. The papers were circulated in advance and were not read in full, the authors being asked merely to introduce them briefly and to answer questions. This excellent plan left plenty of time for discussion and was undoubtedly largely responsible for the success of the meeting. The many lively discussions were skilfully guided by the chairman, Dr. C. H. Holmes, of the Ceylon Forestry Department.

In addition to the presentation and discussion of papers, which took about half the available time, discussions were held on five general themes chosen by a steering committee. Each theme was introduced and summed up by a chosen speaker, as follows: ecological factors in the tropics with special reference to the definition of dry seasons (Prof. G. Mangenot, France), vegetation types and their subdivisions, including methods of study (Prof. F. R. Bharucha, India), vegetation mapping (Dr. F. R. Fosberg, United States), the concept of the climax as applied to tropical vegetation (Prof. P. W. Richards, United Kingdom) and regeneration as a factor in judging the status of vegetation types (Prof. C. G. G. J. van Steenis, Holland). The discussions left no doubt of the vigorous activity and lively interest in the field of tropical ecology. There was a general feeling that the methods and concepts of ecology are too largely based on experience in temperate countries, where the vegetation has been modified by human activities for a very long period of time. This point of view was expressed perhaps most forcibly by Prof. van Steenis in a paper dealing with the basic principles of plant sociology as applied to tropical rain-forest vegetation. He claimed that homogeneous samples such as current plant sociological methods require cannot be found in rain forest of the usual type, while the concept of the plant association as a unit of constant composition and definable boundaries is one which could have evolved only in temperate regions with their impoverished and specialized flora and largely anthropogenic plant communities. "If plant sociology had been developed in a tropical country," he said, "it would have another face to-day. In fact the whole of botany would have another face if it had developed in the tropical zone." It is clear that the study of tropical vegetation is likely to develop rapidly in the near future, and that the proposal of some of the Indian members of the symposium to found an international society for tropical ecology is likely to be widely welcomed.

On the afternoon of its third day the symposium adopted a series of resolutions aiming at the promotion of ecological research in the tropics. These were presented to the preparatory meeting, which endorsed them and forwarded them to the Director-General of Unesco.

The preparatory meeting of experts on humid tropics research elected Mr. D. Rhind, secretary of the Committee for Colonial Agricultural Research (Colonial Office), as its chairman. Its main purpose was to propose the formation of a permanent advisory committee of Unesco for humid tropics research and to define the scope and method of functioning of this committee. Some discussion took place on the exact meaning of the term 'humid tropics', which is difficult to define, since there are large parts of the tropics which receive a heavy rainfall unevenly distributed through the year so that the climate is only seasonally humid. It was finally decided that a rough line of division should be drawn in agreement with Unesco's Arid Zone Committee, so that there should be no overlap and no omission of intervening regions from the field of interest of either committee.

There was also discussion on the meaning of 'fundamental research'. Though the general feeling seemed to be that the main duty of the proposed committee should be to provide or initiate research on the basic underlying scientific problems of the humid tropics, some members were opposed to defining its field in such a way as to exclude all kinds of 'applied' research. Careful consideration was given to avoiding overlapping with other international organizations concerned with research such as the Food and Agriculture Organization, the World Health Organization and the Commission for Technical Co-operation in Africa South of the Sahara ('C.S.A.'). There were certain fields of research such as geology and human health and physiology under humid tropical conditions which the meeting considered were probably adequately cared for by existing organizations, but which it was unwilling to exclude formally from the field of interest of the proposed committee.

Papers on an enormous range of subjects covering such diverse fields as zoological surveys, coral atoll ecology, reclamation of swamp land in Brazil, pedology, climatology, research on medicinal plants and much else were laid before the meeting, as well as requests for financial support to various research projects, several of which were recommended to the Director-General of Unesco for favourable consideration. A remarkable feature was the number and diversity of the requests for more taxonomic work on both plants and animals (especially insects) in the tropics. Many speakers made it evident that the lack of modern Floras and other taxonomic works for many tropical countries is at present an insuperable hindrance to research in a great many fields. The remedy depends on trained man-power as well as on finance; but it is clear that the belief that the biological sciences in the tropics can progress in the absence of strong support to taxonomy is quite unrealistic.

The preparatory meeting accepted gratefully an invitation from the delegate for France that the new Humid Tropics Advisory Committee, which Unesco has been asked to set up, should hold its first meeting, if possible in 1957, at Abidjan in the Ivory Coast. At the symposium on tropical vegetation it was recommended that this meeting should be preceded by another symposium with the theme "Ecological Studies of Tropical Vegetation in Relation to Soils".

P. W. RICHARDS

GEOCHEMICAL AND GEOPHYSICAL LABORATORIES IN THE IMPERIAL COLLEGE

By PROF. DAVID WILLIAMS

ONE of the initial steps towards the goal of full expansion of the Imperial College of Science and Technology, London, has been the addition of a top story to the Royal School of Mines. This story, incorporated in the Department of Geology, provides about 11,000 sq. ft. of accommodation for the Sub-departments of Geochemistry and Applied Geophysics, which are mainly concerned with training and research in certain modern aspects of mineral exploration. The new laboratories were open to inspection on May 24.

The Geochemistry Section comprises a main laboratory for the chemical analysis of minerals, rocks and soils, two laboratories devoted to spectrochemical analysis and the study of trace elements in geological material by means of large quartz spectrographs and other modern instruments, together with sample preparation and balance rooms. X-ray equipment for mineral identification is available, and a mass spectrometer is shortly to be installed. Several research cubicles are provided for postgraduates engaged in the investigation of a wide range of problems in pure geochemistry and geochemical prospecting.

Analysis of silicate rocks by the so-called classical methods is a protracted and highly skilled technique. Fortunately, however, rapid spectrochemical methods of silicate analysis, recently devised in the United States and substantially modified as the result of research in the new Pure Geochemistry Laboratories of the College, now permit a productivity of ten complete and reliable analyses per man-week. Thanks to this increased tempo the Department has been able to make comprehensive studies of the chemical changes induced in sediments by the emplacement of granites in Donegal, and to investigate chemical variations in the serpentinized basic igneous rocks of Insch in the Scottish Highlands. The research programme in pure geochemistry also includes a comparison of different analytical procedures, using spectrographic, polarographic, chromatographic and colorimetric techniques. This study should indicate the most appropriate method to adopt for determining particular elements, and it is hoped eventually to offer interested workers in other universities and research establishments a variety of silicate rock powders of guaranteed major- and minor-element composition.

Although much is known about the partitioning of certain elements among different minerals and among varieties of particular species, little research has yet been concentrated on the geochemistry of the less common metals, including those of the rare-earth group. Timely investigations, however, are now under way in the new Department concerning the distribution in minerals of cerium, gadolinium terbium and other rare-earth elements, knowledge of which will be especially valuable in view of the increasing interest in atomic energy. Regional studies of the distribution of trace elements in specific ore minerals continue to receive attention, and the dispersal of certain elements throughout soil profiles in temperate regions is under consideration. A virgin field of attractive research in nuclear geology awaits the arrival in the Department of a mass spectrometer capable of determining the isotopic abundance of a wider range of elements than has hitherto been investigated anywhere. Among the many problems to be studied is the isotopic constitution of copper zinc and other metals within a single sulphide deposit and within a particular mineralized district, an inquiry which should not only shed light on the origin of the deposits but may also herald a novel approach to mineral exploration.

In applied geochemistry, a flourishing research school is primarily concerned with critical studies of existing methods of geochemical prospecting, with the development of new field and laboratory techniques, and with the fundamental principles involved in the formation and detection of geochemical anomalies of economic significance. Geochemical methods of prospecting rely on the presence o significant traces of metals naturally dispersed in the rocks and soils near an ore-body, in the vegetation growing on these soils, or in the waters and sediment of streams draining the mineralized area. Thus although there may be no visible manifestations o mineralization, the presence of concealed mineral deposits may be revealed by the detection o anomalous concentrations of metals in surface materials. Since the concentrations involved are usually very minute, rapid and simple trace analytical techniques have been specially devised to detec them. A Geochemical Prospecting Research Centre has been established in the Department, partly with the aid of funds from the Colonial Office and th Department of Scientific and Industrial Research and active research is being carried out in variou parts of Africa and Britain in mineralized areas containing cobalt, copper, gold, lead, zinc and othe metals. Results to date augur well for the continued success of this new method of discovering minerals.

The Applied Geophysics Department is provided with a diversity of modern prospecting instruments including vertical and horizontal magnetometers, a Worden and a North American gravity meter, seismi equipment and a variety of electrical instruments for spontaneous polarization, resistivity and electo magnetic surveys. Facilities are available for testing and calibrating these instruments and also for measuring some of the relevant physical properties of rocks and minerals. In the students' laboratory model experiments, simulating field conditions, have been developed to illustrate many of the principles employed in geophysical prospecting. A main laboratory and a number of small ones are devoted to research, and a workshop affords facilities for the construction and development of special equipment.

Current research in geophysics includes gravity-meter surveys along the margin of a gabbro mass near Insch in Scotland, and the development of an automatic method of computing the gravitational effects of various types of geological bodies. Studies of Tertiary igneous rocks in Mull and North Wales have indicated that during their extrusion or intrusion many of these rocks were magnetized in a direction opposite to that of the Earth's present field. While any theory of the Earth's magnetism must account for this adverse magnetism, possibly by invoking a reversal of the Earth's field in the geological past, the results obtained in these academic studies have an obvious bearing on the geological interpretation of magnetic surveys for mineral deposits. An attempt is now being made to use the techniques of palæomagnetism for studying the physical conditions which operated during the emplacement of granites and the injection of dykes.

On the instrumental side a flux-gate magnetometer (of the type used in aeromagnetic surveying) is being modified for use at sea, to be towed behind a ship; with this instrument it is hoped soon to make magnetic measurements in the North Atlantic. Development of a novel type of magnetometer based on nuclear magnetic resonance is expected to result in the speeding up of magnetic surveys on land, the instrument consisting essentially of a bottle of water, an electromagnet and a detector coil to measure the frequency of proton precession.

Seismic research is directed towards the production of simpler and more reproducible shocks, using an electromechanical device. Investigations, particularly of frequency attenuation and phase changes, are being continued and the new technique should prove valuable in helping to decipher shallow geological structures. Promising results have attended the evolution of an induced polarization method of locating good conducting ore-bodies enveloped by an electrolyte, and equipment is now being constructed for field-trials over known metalliferous deposits.

OBITUARIES

Prof. S. R. K. Glanville, F.B.A.

Stephen Ranulph Kingdon Glanville, Provost of King's College, Cambridge, and Herbert Thompson professor of Egyptology in the University, died, very suddenly, on the morning of April 26, his fifty-sixth birthday. The news of his death came as a great shock, not only to his professional colleagues, but also to men and women in many countries; for there were few who knew him who did not come to rely on him for friendship and sympathy.

Glanville was the eldest son of Stephen James Glanville and was born in Westminster in 1900. He was educated at Marlborough and at Lincoln College, Oxford, where he was a modern history scholar. He graduated in Literæ Humaniores in 1922. Chance largely led him to accept a post as an English teacher in the Egyptian Delta town of Mansūrah. Once there, he fell in love with the country and its people, and set himself to study them. He joined the Egypt Exploration Society's excavations at Tell-el-Amarneh in the season of 1923, the beginning of his long record of devoted service to the Society as a field-worker, and as member and chairman of committee. In 1924, he was appointed an assistant keeper in the Department of Egyptian and Assyrian Antiquities in the British Museum, where he remained until 1933. He returned, however, to Egypt to work at his beloved Tell-el-Amarneh in 1925, and at Armant in 1928, and contributed to the publications on both sites. He held the Laycock Studentship of Egyptology at Worcester College, Oxford, during 1929–35.

At the British Museum, the major outstanding task of the Department was the publication of its demotic papyri. Demotic is a cursive script in which the Egyptians wrote their documents from the seventh century B.C. until the fourth century A.D.; and in 1924 there were comparatively few aids for its study. Inspired by Sir Herbert Thompson, who became his teacher, benefactor and friend, Glanville undertook this task and did pioneer work. His "Catalogue of the Demotic Papyri in the British Museum, Vol. 1: A Theban Archive of the Reign of Ptolemy I Soter" (1939), and Thompson's "A Family Archive from Siut" (1934), set a new standard and method for the publication of demotic contracts. By painstaking compilation of family genealogies and topographical plans of streets and houses, they made the dry legal formulæ yield up a brilliant and intimate picture of the social and family life of Egyptian provincial towns in the Ptolemaic period. Vol. 2 of Glanville's "Catalogue", "The Instructions of 'Onkhsheshonqy" (1956), of which he received the first copy a few weeks before his death, broke fresh ground; in it he deciphered and translated what may well be the last great "Wisdom" book from Egypt. His deep understanding, both of Egypt and of human nature, enabled him often to interpret what might have remained dark to a more cloistered mind; while his firm critical judgment and keen historical sense controlled his imagination and ensured his accuracy.

But Glanville was by no means a one-sided scholar. During his time at the Museum, apart from editing the valuable "Studies presented to F. Ll. Griffith" (1932), he published many articles on the earlier literature and history of Egypt, and acquired a deep knowledge of Egyptian objects, for which he had always had a rare feeling. This became of the utmost importance at University College, London, where he was appointed a reader in 1933, and in 1935 Edwards professor of Egyptology; for his chief task there was the cataloguing of the Petrie Collection. Unfortunately, his work for it was undone by the Second World War. Meanwhile, he edited the "Legacy of Egypt" (Clarendon Press, 1942). During the War he served in the Royal Air Force, in which he reached the rank of wing commander, and was made M.B.E. and received Czechoslovak, Dutch and Yugoslav decorations. In 1946 he was appropriately appointed to the new chair, founded by his old master, Sir Herbert Thompson, at Cambridge, specifically for demotic and coptic studies, and was elected a professorial Fellow of King's. In the same year he was elected a Fellow of the British Academy, and recently became an honorary Fellow of his own College, Lincoln, Oxford.

At Cambridge, Glanville devoted himself not only to building up the new Department of Egyptology, its library and collections, but also served the University, his College and his Faculty in a host of functions. His courage, clear-sightedness and grasp of principle were always tempered by his warmth, his tact and his humour. Such was the trust and affection in which he was held in his College, that he became in 1954 the first Oxford man ever to be elected Provost of King's College, Cambridge. The loss of his wisdom and friendship there is as grievous as it is to his Department and students. For he was the finest type of teacher; he never spoon-fed, but worked unsparingly and sympathetically to inspire his students to make the best of their own abilities, not in their studies alone, but also in the whole of their life. His life will be an inspiration, his kindness a poignant memory, to his many friends.

H. S. SMITH

Prof. Edward Stenz

EDWARD STENZ, who died after a long illness in Stockholm on February 21 at the early age of fifty-six, had many friends among meteorologists and geophysicists all over the world.

Born in Warsaw, he went to a secondary school there (the Rey Gymnasium); even as a pupil he became an enthusiastic member of the physics section under the leadership of Ziemecki, who after the War took a chair of physics at the Maria Curie SkŁodowska University of Lublin.

Stenz studied in the University of Warsaw unde Kowalski, Pieńkowski, Gorczyński, Mazurkiewic and Sierpiński; he also spent some time at the Ja Kazimierz University of Lwów, working unde Arctowski. He took his Dr.Phil. degree at the Stefa Batory University of Wilno.

After graduating, Stenz became a lecturer in th Physics Department of the University of Warsaw and was afterwards in charge of applied physics a the Technical University of Warsaw; later he wa appointed director of the Observatory at Kasprowy Wierch in the Tatra Mountains. He spent the perio of the Second World War in Afghanistan, being i charge of the Meteorological Office and professor i the University at Kabul. After the War he wen back to Poland and was appointed professor o geophysics in the University of Warsaw. He serve as president of the Geophysical Committee of th Polish Academy of Sciences, deputy director of th Institute of Geophysics, and president of the Polish Meteorological and Hydrological Society. He wa the author of about ninety papers, covering a wid range of subjects—meteorology, terrestrial magnetism, the Sun and terrestrial radiation and gravimetric measurements; he also published severa semi-popular books. All his papers were marked by a clear and attractive style as well as by a high standard of presentation. He was one of the firs organizers of the meteorological service for the Polish Air Force.

Stenz was very sensitive, full of stimulating ideas kindly disposed to others and always ready to give a helping hand to those in trouble. In the summer o 1954 he experienced a great blow: his only daughte fell to her death, while climbing in the Tatra Mountains. His own death means a great loss to Polish science and has deprived all who knew him of one of their most valued friends.

JÓZEF MAZUR

NEWS and VIEWS

Kelvin Gold Medal

THE Kelvin Gold Medal for 1956 has been awarded to Sir John Cockcroft, director of the Atomic Energy Research Establishment, Harwell. The Medal is awarded every three years to a person of any nationality "as a mark of distinction in engineering work of the kinds with which Lord Kelvin was especially identified", and the administration of the award is in the hands of a committee consisting of the presidents of the Institutions of Civil Engineers, Mechanical Engineers, Electrical Engineers, Naval Architects, Mining and Metallurgy, Mining Engineers, and Engineers and Shipbuilders in Scotland, and the Iron and Steel Institute.

Royal Meteorological Society: Awards

THE Royal Meteorological Society has made the following awards: *Buchan Prize*, founded in memory of Alexander Buchan, secretary of the Scottish Meteorological Society during 1861–1907, for the period 1951–55 has been awarded to Mr. F. H. Ludlam (Department of Meteorology, Imperial College of Science and Technology), for his outstanding contributions to the study of cloud physics; *Hugh Robert Mill Medal and Prize* for 1956, founded in memory of Hugh Robert Mill, director of the British Rainfall Organization during 1901–19, has been awarded to Mr. J. S. Sawyer (director of the Forecasting Research Division, Meteorological Office) for his outstanding contributions to the science of meteorology, with particular reference to rainfall.

Linnean Society of London

AT the anniversary meeting of the Linnean Society of London held on May 24 the Linnean Gold Medal for 1956 was awarded to Prof. W. H. Lang, emeritus Barker professor of cryptogamic botany in the University of Manchester. The following were elected officers of the Society for the session 1956–57: *President*, Dr. H. Hamshaw Thomas; *Treasurer*, Sir Frederick Stern; *Secretaries*, Dr. H. R. Hewer (zoology) and Dr. C. R. Metcalfe (botany); *New Members of Council*, Mr. D. Etherington, Dr. B. M. Hobby, Dr. Doris M. Kermack, Dr. John Smart and Dr. Errol I. White. Prof. I. W. Bailey, Dr. Anton Brunn, Prof. J. A. Efremov, Prof. Richard Harder, Prof. Bernhard Rensch, Prof. Karl von Frisch and Prof. Ø. Winge were elected foreign members of the Society.

Presidency of the Institute of Fuel: Mr. J. R. Rylands

Mr. J. R. Rylands, who has recently been elected president of the Institute of Fuel and will take office in October next, served his engineering apprenticeship with Henry Berry and Co., Ltd., of Leeds, and then, after service in the Army during the First World War, graduated from the University of Leeds. He worked at first as an electrical engineer with the Taquah and Abosso Gold Mining Co., of the Gold Coast, but later transferred to E. Green and Son, Ltd., of Wakefield, makers of fuel economizers, of which company he is now chief engineer and a director. For his work done with J. R. Jenkinson during the Second World War on fouling problems associated with economizers and air heaters, he received the John Hopkinson Premium for 1943 of the Institution of Electrical Engineers, and this work was followed by further research into the corrosion of boiler, economizer and air-heater surfaces, for which he was awarded the Thomas Lowe Gray Prize for 1948 of the Institution of Mechanical Engineers. Mr. Rylands has been active in the electrical branch of the engineering profession, having served as chairman of the North Midland Centre of the Institution of Electrical Engineers.

J. A. C. Chaptal, Comte de Chanteloup (1756–1832)

The distinguished chemist and statesman, Jean Antoine Claude Chaptal, who was born at Nogaret, Lozère, two hundred years ago on June 4, 1756, is to-day remembered chiefly for his contributions to the technical development of modern industry by the application of the science of chemistry, and for having coined the name for nitrogen. The son of an apothecary, he owed his education to a rich uncle, Dr. Claude Chaptal, and in 1777 he graduated M.D. at the University of Montpellier. After studying science in Paris, in 1781 he was appointed to a specially instituted chair of chemistry at Montpellier, where he taught the new doctrines of Lavoisier with eloquent lucidity. On the death of his uncle he inherited a large fortune, part of which he devoted to establishing chemical works for the manufacture of mineral acids, alum, white lead and soda. In 1797 he was made director of the saltpetre works at Grenelle by the Comité de Salut Public and greatly simplified the procedure of making gunpowder. Two years later he was created a Councillor of State by the First Consul, and in 1801 he succeeded Lucien Bonaparte as Minister of the Interior. In this capacity he founded a society of industries and a vaccine society, reorganized the hospitals, organized schools of pharmacy, introduced the metric system of weights and measures, and did much to promote the scientific culture of vines. Besides his many scientific honours, he was a grand officer of the Legion of Honour (1805), and received the title of Comte de Chanteloup (1811). On Napoleon's return from Elba in 1815 he became director-general of commerce and manufactures. His best-known writings are "Éléments de Chimie" (1790 and several editions), "Traité des Salpêtres et Goudrons" (1796) and "L'Art de faire les Eaux-de-Vie" (1819). He died in Paris on July 30, 1832, at the age of seventy-six.

Joseph Pitton de Tournefort (1656–1708)

Joseph Pitton de Tournefort, who was born at Aix three hundred years ago on June 5, 1656, is remembered as a pioneer botanical systematist whose classification of groups higher than genera was accepted until the time of Linnæus. Born of a noble family, he was intended for the church, but after his father's death in 1677 he devoted himself wholeheartedly to his first love, namely, botany. He studied medicine at Montpellier and also at Paris, where in 1683 he became professor of botany at the Jardin Royal des Plantes. In 1692 he was elected to the Royal Academy of Sciences, Paris, and he received the M.D. of Paris in 1698. Two years later he was sent by the king to Spain, Portugal and Asia Minor to collect botanical material. Reviving the concept of genera and species originated by Kaspar Bauhin, he provided his genera with names and characters, adding the species and varieties without special description. He refused to accept the doctrine of sexuality in the vegetable kingdom formulated by Rudolph Jacob Camerarius, of Tübingen, in 1691–94. Inclined to be dogmatic, de Tournefort regarded the morphology of the flower and fruit as the proper basis for classification, founding his system on the form of the corolla. His most important work was "Eléments de botanique ou méthode pour connaître les plantes" (1694; three volumes with 451 plates). He also compiled a materia medica, which was published in French after his death, an English translation appearing in 1708. A tremendous worker and a vivacious, gay and charming personality, de Tournefort died on November 28, 1708, at the age of fifty-two.

Nature Conservancy

The Committee of Privy Council for Nature Conservation has appointed the following as members of the Nature Conservancy: Lord de Ramsey, Colonel J. C. Wynne Finch, Sir Graham Sutton (director of the Meteorological Office) and Prof. A. R. Clapham (professor of botany in the University of Sheffield). The vacancies have arisen through the death of Sir Arthur Tansley, and the retirement of Prof. R. Alun Roberts, Prof. R. C. McLean and of Mr. C. S. Elton, who remains a member of the Scientific Policy Committee. The following members have been reappointed for a further term of service: Lord Strang, Lord Hurcomb and Dr. E. B. Ford.

Technology as an Educational Discipline

The presidential address to the Institution of Mining and Technology, given on May 17 by Prof. C. W. Dannatt, professor of metallurgy in the Imperial College of Science and Technology, London, was concerned with the study of technology as a branch of education. Discussing how education is acquired, he pointed out that the study of history and the study of science have much in common, following almost identical rules which should engender habits of high moral and intellectual worth: patient and persistent industry; an honest receptivity which accepts substantiated facts even when counter to preconceived beliefs; freedom from prejudice, and a willingness to abandon the most cherished thoughts and theories in the face of evidence; self-reliance and a readiness to challenge statements that seem open to doubt; and clarity of thought combined with constant and painstaking practice in logical inference and deduction. If these qualities become so ingrained in the mind that they are applied in every circumstance of life, the scholar, no matter what his subject of study, will be a cultured man. Accordingly, the failings of the over-specialized scientist or technologist are due not to the subject of study but to the neglect of matters that should be of interest. Prof. Dannatt claimed that technology when properly used is a satisfactory and efficient implement of culture, but he thinks that we shall eventually be forced to restrict the field of our technologies, and possibly to lengthen the courses so as to maintain standards. He also suggested that we must discard the foolish idea that budding technologists can be identified by examination at the age of eleven or twelve, and that their studies may safely be narrowed and restricted within no more than three or four years. We should also remove the load of specialized studies from the schools and leave them free to perform their task of providing a general basis of education. Technological studies can provide the discipline and basis essential to culture but, like other advanced studies, they need that broader basis of general knowledge which can be developed into vision and understanding.

Technology and the Universities

In his presidential address to the Association of University Teachers on May 25, when he spoke on "Technology and the Universities", Prof. J. L. Montrose, professor of law in The Queen's University, Belfast, submitted a reasoned claim that technology has not merely a place within universities, but is in fact better studied there than elsewhere. He based this claim on the creativeness of application and on the reality of scientific activity in many departments of knowledge. The qualities which constitute the life of reason can be manifested both in the discovery and in the application of knowledge. Moreover, the inclusion of technology within universities can be supported not only by theoretical arguments of the liberating character of thought about problems of the utilization of science but also by descriptive consideration of what happens in such departments—the keen interest in science of their undergraduates and the valuable contribution which the research work of their staffs makes to the understanding of Nature and to scholarship in general. Prof. Montrose summarized the qualities required to ensure that a subject is taught at a university-level with depth and perspective. It is by means of thoroughness that we can attain the broad outlook which sees details of a subject as the application of basic principles, sees principles as seminal ideas growing into the processes by which human problems are treated, and which sees the connexions between one subject and others and the whole of life. Prof. Montrose added that university teachers have not given sufficient thought to the problem of testing intellectual qualities other than the mnemonic. We should endeavour to test not solely powers of recollection and expression but also such other qualities as the ability to discover information about a subject, to apply the principles of a subject to new situations, to comprehend a new and complex statement and to analyse it in relation to criteria for testing its accuracy and, above all, to test inventiveness and imagination. Finally, Prof. Montrose stressed the importance of the quality of staff in our technological institutions and of providing conditions of service that would attract outstanding men and women.

Direction Indicators for Motor-Vehicles

On May 16 the Minister of Transport and Civil Aviation, Mr. H. Watkinson, replying to a question, stated that he has received the final report of the Road Research Laboratory on the comparative meri of the different types of direction indicators now i legal use on motor-vehicles in Britain and that h has reached the conclusion that all three types o direction indicator now permitted should continu to be legal, both to meet the needs of different kind of vehicles and also as an aid to the export trade The report is being circulated, and the Ministe intends also to circulate to interested organization proposals for the amendment of the construction an use regulations. These regulations would requir direction indicators fitted to vehicles registered afte the end of 1958 to be amber in colour, neither t exceed nor fall below certain standards of brightness and, if of the fore-and-aft flashing type, to b separated from other lights. The Laboratory ha concluded that direction indicators should be ambe in colour, with an intensity between 100 and 50 candle-power, and that this colour should not b used for other vehicle lights. They are best mounte on the side of a vehicle, roughly at the level of th driver's eye, and should emit light forward an backwards and also appreciably at right angles. N consistent evidence in favour of a flashing rathe than a steady light of equal intensity has been foun by the Laboratory, and no change in existing practic is recommended, although it is desirable that on type of indicator should be selected for genera adoption and alternatives avoided. Uniformity o type of indicator, position, intensity and rate o flash are important, and means for ensuring th observance of standards are desirable.

The Calder Hall Pile

The first of the two atomic piles in the Calder Hal Power Station, which will be the first in the world t supply electricity on a large scale from nuclea sources, has started working. Physical measurement and instrument checks are now taking place, and th gradual commissioning of the plant will follow. H.M the Queen will perform the official opening of th Station on October 17. For the first time in th history of the world, electricity on a large scale wil then be supplied from a nuclear power station to national electricity network.

Calder Hall is part of the Atomic Energy Authority' programme for power stations and is not included i the national programme, which envisages the con struction of twelve atomic power stations by elec tricity authorities during the next ten years at a estimated cost of £300 million. The Atomic Energ Authority is also building a replica of the first powe station on the same site, and another with fou reactors at Chapel Cross, Annan, Dumfriesshire These have the dual purpose of producing electricit and making plutonium for the military programme Another atomic power station at Dounreay, Caith ness, will have an experimental fast breeder reacto capable of creating more fissile material than it burns

Power from Fusion

The United Kingdom Atomic Energy Authority i holding a one-day symposium on controlled thermo nuclear energy on June 4 at Harwell which will be o a classified basis. Invitations have been sent t representatives of industrial research laboratories i addition to government research establishments an British universities. About fifty people have bee invited in addition to the Authority's own staf The object of the symposium, at which a genera account of the Authority's own project will be given is to encourage fundamental research work along lines which will assist the work of the Authority in this field. Research on the control of the thermonuclear reaction has been going on at Harwell for some time. The conference will be held in private, and no statement will be issued afterwards.

Central Pool of Officers for the Oversea Civil Service

On May 17 the Secretary of State for the Colonies, Mr. A. Lennox-Boyd, made a statement regarding the Oversea Civil Service, further details of which were given in a White Paper published the same day. Mr. Lennox-Boyd said that the Government has decided in principle to establish a central pool of officers with exceptional administrative or professional qualifications who would be employed by the Government in the United Kingdom and be made available as required for secondment to overseas Governments. The central pool will be set up as soon as possible. Meanwhile, to meet an urgent staffing position which has arisen in the territories comprising the Federation of Nigeria, it is proposed, subject to the agreement of the Nigerian Government, to introduce a scheme by which existing expatriate pensionable officers can transfer, on certain conditions, to a special list of the Oversea Civil Service, and officers so admitted will thenceforth be in the service of the Government and seconded to the local Governments. The scheme will be in a form that will permit similar arrangements to be applied to other territories if considered desirable. In reply to questions, Mr. Lennox-Boyd added that officers transferred to the special list will be paid by the employing countries, at rates prescribed by the British Government after consultation with those countries, and that H.M. Government will pay the pensions and recover the money from the Government in whose service the pensions were earned.

Fluoridation of Potable Water in Britain

In view of repeated allegations that the addition of fluoride to public water supplies might have harmful effects, the Minister of Health has again consulted the Medical Research Council. The Council has transmitted to the Minister the advice of a conference of experts, which it called to review the subject, that there is no evidence warranting alteration or abandonment of the fluoridation projects. The experts agreed in general with the conclusions of the United Kingdom Mission (1953) to the effect that, despite considerable interest and research, there is no definite evidence that the continued consumption of fluorides in water at a level of about 1 p.p.m. in drinking water is in any way harmful to health, and they consider that if any untoward effect is revealed by future research this is most unlikely to be serious.

Industrial Welfare Society

In the annual report for 1955, the director of the Industrial Welfare Society, Mr. John Marsh, suggests that side by side with the demands for scientific and technical achievement in industry, there is a great need for men who have personal qualities and who can influence workers at all levels to be self-respecting, co-operative and efficient. Personal qualities are not only needed among those concerned with management but also among the specialists. The technical specialists of industry can create human problems which sometimes offset the efficiency they set out to achieve. For example, the need for work-study engineers is undoubtedly great; but industry must select men for training in these tasks who are fundamentally sound in their knowledge and understanding of their fellow men. They must certainly know something about the effect of changes in skill on a man's reason and emotions. Among other items referred to by Mr. Marsh are the lack of clearly defined promotion systems in the majority of industrial concerns and the amazing dearth of suitable reading matter for the large number of supervisors and apprentices in industry.

A Bibliography of Plant Protection

Under this title a comprehensive work covering the year 1951 has been issued in German, English and French by the Biologische Bundersanstalt für Land- und Forstwirtschaft in Berlin-Dahlem, under the editorship of Dr. J. Barner (pp. xliv+420; Paul Parey, Berlin and Hamburg, 1955). This bibliography, which comprises more than 12,500 titles, is in continuity with the original publication on this subject begun in 1921 and already including twenty-two volumes covering the years 1914–45. The volumes covering the years 1946–50 are to follow in the near future. The original layout has been maintained and includes a general section dealing with collective works, text-books, reports of congresses, bibliographies, etc., followed by other sections on diseases and their causes, diseases and host plants, measures of plant protection and an index of authors.

University of Leeds: Appointments

Dr. C. E. Lumsden, of the Institute of Neurology, London, has been appointed professor of pathology and head of the Department of Pathology in the University of Leeds. The following have been appointed lecturers in the University: Dr. R. O. Gandy (applied mathematics), R. J. R. Hayward (Brotherton lecturer in inorganic and structural chemistry), Dr. G. E. Higginson (mechanical engineering), M. A. Jeeves (psychology), Dr. L. Mackinnon (physics), P. Sutcliffe (civil engineering) and W. H. Trickett (statistics).

University of London: Appointments

Mr. J. D. Evans, Research Fellow at Pembroke College, Cambridge, has been appointed to the University of London chair of prehistoric European archæology, tenable at the Institute of Archæology, and Dr. J. H. Birkinshaw, reader in biochemistry at the London School of Hygiene and Tropical Medicine, has been appointed to the University of London chair of biochemistry, tenable at that School. The following have been appointed to University readerships tenable at the Colleges indicated: P. T. Fink (Imperial College of Science and Technology), aeronautics; Dr. G. P. Wibberley (Wye College), agriculture with special reference to agricultural economics; and Dr. W. L. Wilcock (Imperial College of Science and Technology), instrument technology.

University of Sheffield

In the University of Sheffield the Refractories Section of the Department of Metallurgy has been created a separate Department of Refractories Technology with Prof. J. White as its head. The title of reader in electrical machinery in the University has been conferred on O. I. Butler, senior lecturer in electrical engineering. Dr. G. B. Greenough, senior lecturer in physical metallurgy, has resigned from the University on appointment as research manager, Atomic Energy Authority (Industrial Group), Windscale, Cumberland.

Announcements

DR. LEE A. DUBRIDGE, president of the California Institute of Technology, has been elected a member of the Board of Trustees of the Rockefeller Foundation, New York.

MR. T. D. WHITTET, chief pharmacist at University College Hospital London, has been elected a foreign member of the Royal Spanish Academy of Pharmacy, founded in 1589 as the Brotherhood of the Apothecaries of Madrid and one of the oldest pharmaceutical organizations in Europe.

REPLYING to questions in the House of Commons on May 15, the Parliamentary Secretary to the Ministry of Works, Mr. J. R. Bevins, said that the research associations as a whole spend about one-quarter of their budgets, or more than £1 million a year, on development. Several development companies have been formed by the research associations, and the Government is also starting some civil development contracts with scientific research associations.

THE Challenger Society is prepared to make small grants for research in marine biology or oceanography at a recognized laboratory during the year June 1956–June 1957. Applications, accompanied by details of the proposed research, should reach the Honorary Secretary, Challenger Society, British Museum (Natural History), London, S.W.7, before June 11.

A SYMPOSIUM on "Rheological Research in the Textile Industry", arranged by the British Society of Rheology, will be held at the British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester 22, during June 7–8. Further information can be obtained from Dr. A. S. Lodge at the Association.

THE summer conference and annual meeting of the Society for Applied Bacteriology will be held in Reading on July 16–18. In addition to the usual programme, there will be a whole-day excursion to the Microbiological Research Department of the Ministry of Supply at Porton. Further information can be obtained from the honorary secretary, G. Sykes, Boots Pure Drug Co., Ltd., Microbiology Division, Standards Department, Nottingham.

THE eleventh annual physics congress of the Canadian Association of Physicists will be held in the University of Montreal during June 14–16. Included in the programme will be three symposia on the following topics: high-energy physics and accelerators; geophysics; and the teaching of high-school physics. Further information can be obtained from the Association, c/o the Department of Physics, McMaster University, Hamilton, Ontario.

THE Royal Institute of Chemistry has arranged a symposium on "Recent Advances in the Chemistry and Industrial Applications of Cereals", to be held in the University of St. Andrews during June 25–29. The three sessions will be concerned with the following topics: production of cereals; processing and testing of grain and grain products; and applications of cereals. Application forms and further information can be obtained from the Secretary of the Institute, 30 Russell Square, London, W.C.1.

AN international conference on "Chemical Engineering in the Coal Industry", sponsored by the National Coal Board, will be held during June 26–29 in the new laboratories of the Board's Coal Research Establishment at Stoke Orchard, near Cheltenham, Gloucestershire. The conference will comprise four technical sessions: physical and chemical pre-treatment of coal; fluid bed carbonization; briquette carbonization; and liquid by-products. Seven papers given by British, French, German, Dutch and American workers will be read and discussed. English, French and German will be the working languages. Attendance will be by invitation only.

AN international congress on automation, organized by the Department of Mechanics of the Conservatoire National des Arts et Métiers, Ministry of Public Education, will be held in Paris at the Conservatoire National during June 18–24. The aims of the congress are to consider certain aspects of general automation and its application to various scientific, technical, economic and psychological fields. It will be divided into three sections: general automation; applied automation; and automation and production. Further information can be obtained from the Secrétariat du Congrès International de l'Automatique, Chaire de Mécanique, C.N.A.M., 292 rue Saint-Martin, Paris 3^{e}.

UNDER the auspices of the International Institute of Embryology a congress on developmental biology will be held in the United States at Brown University during July 23–26, and will be followed by a conference on cytodifferentiation during July 27–31, sponsored by the International Union of Biological Sciences. Applications for both meetings should be sent as soon as possible to Prof. J. Walter Wilson, Department of Biology, Brown University, Providence 12, Rhode Island. Correspondence about the meetings should be sent to G. A. Norton, Developmental Biology Conference Series 1956, National Academy of Sciences, National Research Council, Division of Biology, 2101 Constitution Avenue, Washington 25, D.C.

THE fourth of the annual courses arranged by the Italian Physical Society at the Villa Monastero, Varenna, Lake Como, will be held this year during July 15–August 4 and will be on the magnetic properties of matter. The course will be in English and French, and lectures will be given by the following: C. J. Gorter (Kamerlingh Onnes Laboratory, Leyden), C. Kittel (University of California, Berkeley), N. Kurti (Clarendon Laboratory, Oxford), L. Néel (Laboratoire d'Électrostatique et de Physique du Métal, Grenoble), M. H. L. Pryce (H. H. Wills Physical Laboratory, Bristol), E. M. Purcell (Harvard University), and J. H. Van Vleck (Harvard University). The fee for the course is 30,000 lire (or 25,000 lire for shared accommodation). Applications should be sent at once to the director of the course, Prof. L. Giulotto, Istituto di Fisica dell'Università, Pavia.

ERRATUM. In the article entitled Colonial Research in the British Commonwealth in *Nature* of March 3, on p. 418, reference was made to the work at the Freshwater Field Station at Birnin Kebbi, in Northern Nigeria; it was incorrectly stated that a study of marine invertebrate fauna was in progress. This work is being carried out at Freetown, Sierra Leone. Birnin Kebbi, on the River Sokoto, deals with freshwater investigations, mainly on the fish in the area.

SYMPOSIUM ON THE NEUROHYPOPHYSIS

AN international symposium on the neurohypophysis, arranged by the Colston Research ociety and the University of Bristol, was held in ristol during April 9–12. A generous grant from he Wellcome Trust made it possible to extend ivitations to workers from the United States and anada. Prof. H. Heller (Bristol), director of the ymposium, welcomed the participants and pointed ut that this was the first international meeting ntirely devoted to the subject. He reminded his udience that it was also a scientific anniversary, nce it was fifty years ago that Sir Henry Dale had iscovered the oxytocic effect of posterior pituitary xtracts.

Sir Henry Dale then opened the symposium. In a iscinating survey of the history of the subject, he ecalled that the first evidence for the presence of a iologically active principle in the pituitary gland as obtained by G. Oliver, a Harrogate physician ho, having observed the pressor effect of adrenal xtract, proceeded in collaboration with E. A. chäfer to test extracts of other endocrine glands on ie blood pressure of anæsthetized animals. Sir Henry then mentioned his early experiments on the hemistry of the posterior pituitary principles, which lready then—in 1909—suggested that they were eptides, and described the first separation of oxyocin from vasopressin by H. W. Dudley in his iboratory, work which found its brilliant conclusion nly recently in the establishment of the chemical onstitution of the active peptides by V. du Vigneaud id his co-workers. Similarly, the old difficulty of nderstanding how an organ consisting of neuroglia nd nerve fibres could produce hormones has only ecently been overcome by including the neuroecretory cells in the hypothalamus in the neuroypophysial system. Based on these developments id on recent unpublished work by Dr. Catherine ebb, Sir Henry drew an interesting parallel between ie results of pituitary stalk section and the cutting a cholinergic nerve: in both cases the active rinciple(s) disappears rapidly distal to the cut and cumulates proximally.

The rest of the session was devoted to the morphogical aspect of neurohypophysial secretion. Prof. W. Bargmann (Kiel), reviewing the relation between eurohypophysial structure and function, stressed ie parallelism between the demonstrable amounts neurosecretory material in the neurohypophysis id its hormone content in a variety of physiological id experimental conditions. He discussed the site origin of the neurohypophysial hormones and entioned the unpublished finding of W. Hild that ituicytes in tissue culture are unable to elaborate ie hormones. These cells may, however, be conerned in their release. In conclusion, Prof. Bargann directed attention to the fact that neuroecretory fibres also enter the pars tuberalis and pars itermedia. In the discussion, Prof. B. Hanstrom und) mentioned the rarity of such fibres in the irs intermedia of some mammalian forms, a finding ith which Prof. Bargmann agreed. Dr. H. Rodeck Düsseldorf) gave new evidence for the lack of neuroecretory material in new-born animals and in fants, and Profs. C. Fromageot (Paris) and H. B. in Dyke (New York) agreed that no firm statement can as yet be made as to the chemical nature of the neurosecretory substance.

Prof. Hanström, in a comprehensive and stimulating survey, showed the close similarity in the architecture of the neurosecretory systems of invertebrates and vertebrates. Crustaceans and insects, for example, have not only neurosecretory cells in their brains but also specific storage organs for the neurosecretory material elaborated. In the discussion, Dr. P. A. Jewell (London) described the histological appearance of the neurohypophysis of dogs which have been continuously hydrated for ten days.

The day concluded by the annual reception of the Colston Research Society in the Great Hall of the University, at which the Lord Mayor, the Vice-Chancellor of the University and the immediate past-president of the Colston Research Society, the Bishop of Bristol, were present. The president of the Society, Prof. Macgregor Skene, explained the origin and purpose of the Colston Research Society, and Sir Lionel Whitby, the guest speaker, gave a masterly address on the importance of endocrinology in clinical medicine.

The second day of the symposium was opened with a paper by Prof. C. Fromageot (Paris). He and Dr. R. Acher have investigated the active protein which can be obtained from ox pituitary glands and have found that its pressor and oxytocic activities behave towards chemical and enzymatic agents exactly like the pure polypeptides. Mild processes like counter-current distribution and electrodialysis, which do not involve hydrolysis, dissociate the active protein into substances responsible for the oxytocic and pressor activities and at least one inert protein. This suggested the possibility of a differential release of the hormones *in vivo*. Prof. Fromageot adduced evidence for such difference in hormone release in lactating rats. Prof. H. Croxatto (Santiago, Chile) analysed the chemical and biological properties of polypeptides with posterior pituitary-like activities which can be obtained by the action of enzymes on blood proteins. Though similar in many ways, these artificial peptides differ in some respects from vasopressin and oxytocin. The paper gave rise to discussion on, among other topics, Prof. Croxatto's suggestion that his peptides may be connected with the 'unspecific' antidiuretic and oxytocic effects so frequently encountered in tests with biological material. The third paper of the morning was read by Prof. H. B. van Dyke (New York), who, with characteristic thoroughness and lucidity, reported on problems concerned with the storage and liberation of the neurohypophysial hormones. The relative distribution in the hypothalamic nuclei and the neural lobe differs from species to species; the dog's hypothalamus, for example, is much richer in vasopressin, whereas camel tissue contains more oxytocin. Depletion of hormones stored in the posterior lobe, if severe, affects both hormones, although the teleological requirement may be only for one. In lactating dogs both principles are depleted from the neural lobe; but the depletion of oxytocin is greater. Prof. van Dyke then adduced most interesting new evidence on two forms of vasopressin occurring in mammalian glands. Only hog extracts contain lysine vasopressin; all other mammalian extracts tested (including those of human glands) seem to contain arginine-vasopressin, which has a relatively higher antidiuretic potency than hog vasopressin. In the discussion, Dr. S. J. Folley (Reading) and Prof. G. W. Harris (London) pointed out that differences in hormone ratios found during lactation in different species may be related to different suckling habits.

The afternoon session, under the chairmanship of Prof. J. M. Yoffey (Bristol), was occupied by papers on the metabolism and fate of the neurohypophysial principle. Prof. H. Heller (Bristol) surveyed the subject and queried the applicability of many *in vitro* experiments with body fluids and tissues. Recent results obtained in his laboratory (in collaboration with Dr. S. M. A. Zaidi, of Lahore) show that the kidneys and liver in the intact rat inactivate exogenous and endogenous vasopressin with very great rapidity. In the discussion, Dr. F. Gross (Basle) quoted supporting evidence, and Prof. Fromageot explained that there are three different chemical reactions conceivable by which vasopressin can be quickly inactivated. Prof. R. L. Noble (London, Ontario), in his paper on the excretion of posterior pituitary principles in the urine, described a new method for the extraction of vasopressin from body fluids which allows a consistent recovery of 85–90 per cent of added hormone. He then reported on the occurrence of antidiuretic activity in human urine in conditions like dehydration, fainting, emotional upsets and electro-convulsive therapy.

The third day of the symposium began with a paper by Dr. M. Ginsburg (Bristol), who described experiments which suggest that vasopressin may play a part in maintaining the blood pressure after hæmorrhage. Discussing a variety of stimuli to the neurohypophysis, he emphasized that stimuli for the release of hormones must be distinguished from those which lead to an increase of production of the active principles. He then described experiments in collaboration with Mrs. L. Brown, in which by means of injections of hypertonic solutions into the internal carotid they have unsuccessfully attempted to produce antidiuretic effects in the rat, and enumerated factors which might have prevented such responses. This led to a long discussion on the efficacy of osmotic stimuli to the neurohypophysis, in which Drs. P. A. Jewell (London), M. Pickford (Edinburgh), D. F. Cole (Newcastle), H. E. de Wardener (London), J. C. Sloper (London), H. Croxatto (Santiago) and F. Morel (Paris) participated.

A paper read by Dr. B. Andersson (Stockholm) extended the field of the symposium in a most interesting manner by showing that electrical stimulation of certain areas of the hypothalamus by the elegant 'indirect' method developed by G. W. Harris, or by direct injection of hypertonic sodium chloride solution, induces polydipsia in the goat. This 'drinking area' overlaps partially with that from which antidiuresis can be elicited. This raises the interesting possibility of a dual role of the hypothalamic osmoreceptors in regulating both water intake and water output. Dr. B. A. Cross (Cambridge) pointed out that he has found in the rabbit that stimulation of the paraventricular nucleus results in the release of oxytocin, but that Dr. Andersson has shown for the first time that antidiuretic hormone also can be released by stimulating the same hypothalamic area. Dr. Mary Pickford (Edinburgh), in a paper with Dr. F. B. Brooks (Philadelphia), described experiments which make it possible that oxytocin, by influencing electrolyte excretion, has a physiological action on the kidney This possibility had been envisaged in the rat by Dicker and Heller and Heller and Stephenson; bu Pickford and Brooks have now shown that in certai circumstances oxytocin modifies renal sodium an potassium excretion in the dog also.

The afternoon session was devoted to papers o the mechanism of action of the antidiuretic hormone Prof. H. Wirz (Basle), by accomplishing the astonishing feat of puncturing single distal tubules of th concentrating or diluting rat kidney and analysin the fluid obtained, has been able to support th concepts of H. W. Smith on the site of action of th antidiuretic hormone in the renal tubule. He agree with Dr. W. H. Sawyer (New York), the followin speaker, in postulating that the essential action c the hormone consists in altering the permeability c a section or of sections of the distal tubular epitheliur to water. Both speakers also agreed in the revolutionary assumption that the antidiuretic hormone i not directly concerned in the elaboration of hypertonic urine. Equally interesting was Dr. Sawyer' suggestion that the increase in tubular water absorption, which he has found to be caused in frogs b neurohypophysial extracts, is based on the sam mechanism as their action on the frog's skin.

The first paper on the last day of the symposiur was by Drs. S. J. Folley and A. T. Cowie (Reading who gave an admirable survey of the relations of th neurohypophysial hormones to the mammary glanc The interesting concept was mentioned that th release of the lactogenic and galactopoietic factor from the anterior lobe may be controlled by oxytocin thus uniting the main phases of lactation – mil secretion and milk ejection. Experiments by Folle and Benson relevant to this hypothesis are givin encouraging results. A vivid discussion, in which th chairman of the session, Sir Solly Zuckerman (Bi mingham), Prof. G. W. Harris and Drs. M. Pickforc F. Stutinsky (Paris), I. Chester Jones (Liverpool) an J. C. Sloper took part, developed on the question c the reorganization of the cut pituitary stalk. paper by R. J. Fitzpatrick (Bristol) on the relatio of oxytocin to uterine function followed. He showe that different parts of the uterus vary quantitativel in their response to oxytocin. This was interprete in relation to the requirements for sperm transpoi and the expulsion of the fœtus at term. The thir speaker of the morning, Dr. J. M. Walker (Oxford described experiments with G. W. Bisset in whicl utilizing a method for the extraction of oxytocin an vasopressin from blood, they have investigated th release of the hormone under the influence of drug He made the important point that pharmacologicall the hypophysial synapse differs from that in per pheral ganglia.

The last session dealt with adrenocortical–neurc hypophysial relationships. Dr. R. Gaunt (Summi N.J.), after a critical review of the problems ir volved, reported on new work with C. W. Lloy and J. J. Chart. Their most interesting findin perhaps is that hydrocortisone-like steroids eithe inhibit the release or facilitate the synthesis c vasopressin and of neurosecretory material.

Dr. I. Chester Jones (Liverpool) continued t unravel the relationship between the neurohypc physis and the adrenals by describing the morphc logical and functional changes in adrenalectomize rats with diabetes insipidus. Dr. F. Stutinsky the compared the effect of the ingestion of hypertoni salt solutions on the adrenal cortex of normal ra and animals with diabetes insipidus, and Dr. Lucie Arvy (Paris) showed slides which gave the first suggestion that the neurohypophysis is implicated in the osmoregulation of teleost fishes.

The pleasant atmosphere and the apparently general enjoyment in the symposium can be attributed not only to the restricted number of participants (nearly all of whom were actively engaged in research on its subject) but also to the excellent arrangements of the Colston Research Society, which housed all members in Manor Hall, a hall of residence of the University of Bristol. The scientific meetings were held in the same building, so that much unnecessary inconvenience and loss of time were avoided. The proceedings of the symposium will be published as Volume 8 of the "Colston Papers". H. Heller

EUROPEAN SEISMOLOGICAL COMMISSION

MEETINGS IN VIENNA

THE European Seismological Commission, a Commission set up by the Section for Seismology and the Physics of the Interior of the Earth of the International Union of Geodesy and Geophysics, met in the Institute of Physics of the University of Vienna during April 4–7 under the presidency of Prof. W. Hiller, of Stuttgart. The Commission had the support of Unesco, and nineteen countries were represented. Four topics were discussed: the organization and preparation for carrying out large explosions, particularly in Alpine regions, for seismic purposes; the progress achieved in the preparation of a European Earthquake Catalogue and a seismotectonic map of Europe; the progress made in the design and construction of seismographs, particularly those to be used to record near earthquakes, and the testing of such instruments; and microseisms.

The methods of seismic prospecting for minerals (particularly for possible oil-bearing structures) by letting off small quantities of explosives and receiving the reflected and refracted sound waves on geophones or seismographs are by now well known, and the subject has an extensive literature of its own. It was by this means that the British oilfield at Eakring was discovered. Only one explosion in Great Britain has been large enough to send waves down to penetrate all the layers of the Earth's crust, and this explosion was accidental—namely, the Burton-on-Trent explosion of November 27, 1944. In 1909 A. Mohorovičić found a discontinuity at the base of the continental layers of the Earth's crust in south-east Europe at a depth of 60 km., now called the Mohorovičić discontinuity. Its depth varies over the Earth, but it is almost always present; in France it is estimated to be at a depth of 38 km., and under the Central Appalachians in the United States it is 40–50 km. The possible variation of the depth of the Mohorovičić discontinuity under mountain regions such as the Alps in Europe is particularly interesting, and it is proposed to try to find such depths by using the methods of seismic prospecting with sufficient quantities of explosives so that the P-waves which are generated will penetrate below the discontinuity. The time and place of the explosion, being known, will give fewer unknowns in the calculations than with natural earthquakes, and the arrival times of the reflected and refracted waves, being approximately known, will render possible the use of faster than normal paper speeds in the seismographs and thus greater accuracy in the time measurement. Moreover, since the explosion point is known, it will be possible to arrange the positions of the seismographs to advantage both in azimuth and distance.

The first experiments in western Europe will be carried out by the French during the second half of August 1956 at Briançon. The first explosions will be set off in the middle of a lake which is situated at a height of 2,500 m. above sea-level, and there will be five successive explosions of 1, 2, 2, 5 and 10 tonnes. The first ones will give experience of the best methods, and the whole series will give an idea of the optimum or minimum quantity of explosive necessary for the purpose. The French will set up seismographs situated along two lines which will intersect at right angles at the lake. The explosions will also be recorded by seismographs in Germany, Italy and perhaps in Czechoslovakia. As soon as the results of this work have been studied, the French seismologists propose to make a further series of similar experiments from a lake situated 40–50 km. to the east of the first one, so that records may be obtained over the same ground but in the reverse direction. This is so that true wave velocities may be determined in the manner usual in seismic prospecting. The second series of explosions will probably be held in 1957. As soon as the results of the first French experiments are known, similar explosion experiments will be made in the Eastern Alps, probably in the Hohe Tauern, east of Innsbruck in Austria, but these will not be possible this year.

Experiments in the U.S.S.R. along these lines have already taken place, organized by the Geophysical Institute of the U.S.S.R. Academy of Sciences under Academician G. A. Gamburtzev, the results being communicated to the Vienna meeting by Prof. E. F. Savarensky. The method used by the Russians is called the *GSZ* method and makes use of explosions of 50–300 kgm. of material. The distance between the explosion point and reception point may be up to 400 km. The charges are usually placed in reservoirs, lakes or rivers and are exploded during meteorologically quiet times at night. The effective sensitivity of the reception devices is increased by properly regulated frequency ranges with a maximum amplification, by the increase of the general sensitivity of the equipment under a low level of internal noise and by use of methods of bunching reception. The registration of waves, including radiation of wavelength shorter than usually recorded hitherto, is effected by the use of many-channel stations which permits the most effective correlation methods. Receptors are arranged in different azimuths, and note is taken of the polarization of the oscillations. Different types of waves are distinguished (longitudinal, transverse and surface), as are also differences between single waves and waves resulting from complex interference. Separate crossings of profiles and also groups of reception points are used, the shot point being static.

In particular, large explosions have been made by these methods and for these purposes at Korkino near Chelyabinsk in the Ural Mountains, at Tula in the European part of the U.S.S.R. and in Central Asia. The *GSZ* method was used in pre-mountain and mountain regions of North Tien-Shan, in Western Turkmenia, in Pamiro-Altaisk and other regions. The section from south to north through the mountain ridges of the Kungey-Ala-Tau and Jan Karsky-

Ala-Tau shows two roots going deep into the Mohorovičić discontinuity. The granitic layer shows no roots, but the Mohorovičić discontinuity repeats, with some distortions and with greater amplitudes, the surface relief. It is noteworthy that the foci of all natural earthquakes in the district originate near the basaltic layer, and that the large negative gravity anomaly (up to 250 mgl.) in the district depends mainly on the form of the Mohorovičić discontinuity and not on the granitic layer. The *GSZ* method of deep seismic sounding has thus been used in the U.S.S.R. to study the peculiarities of relief of the internal crustal layers of the Earth (sedimentary, granitic, basaltic), especially in mountain regions; to study these surfaces near deep geological faults; and to give a quantitative physical explanation of the peculiarities of the regional gravitational field. At the Vienna meeting E. Tillotson described the work of Dr. M. N. Hill, of Cambridge, and his co-workers, who use explosions at sea in order to determine the structure of the sea bed. In this method use is made of sono-radio buoys. Prof. H. Menzel and his colleagues at Hamburg intend to follow this method in order to elucidate the very interesting geological structures between Germany and Denmark on one hand, and Norway and Sweden on the other.

Reports from countries represented at the meeting, and also twelve papers, were read concerning the proposed seismo-tectonic map of Europe and the making of the European Earthquake Catalogue. This project is now locally well advanced, and the collection and correlation of the data were placed in the hands of Dr. M. Båth, of Upsala, with the assistance of six colleagues strategically placed in Europe. It is intended, when the map has been completed, to shade it to show the different degrees of seismicity.

Six papers were read at the Vienna meeting, and a good deal of discussion took place, concerning short-period seismographs for the registration of near earthquakes. One paper, presented by Prof. W. Hiller, concerned the new short-period seismographs with magnetic amplification for recording on smoked paper, the prototypes of which have been set up in Stuttgart. The European Seismological Commission recommended the standardization of the constants of short-period electromagnetic seismographs so far as local circumstances permit. Each instrument should have a period (T_m) of the movement of the ground corresponding to a maximum sensitivity between 0·6 and 1·0 sec., and damping coefficients α and β of the pendulum and galvanometer for the seismograph without equivalent reaction, greater than or equal to 0·6. It was left to a small committee under Prof. F. Gassman, of Zurich, to investigate the best methods of testing short-period instruments by shaking-table experiments.

Three papers on microseisms were read, and the Commission passed a resolution requesting the Seismological Commission of the International Geophysical Year to give as soon as possible all the necessary directives for making as complete an investigation as possible of microseismic activity during the International Geophysical Year. Prof. K. E. Bullen, of Sydney, president of the Section of Seismology and the Physics of the Earth's Interior, then gave a lecture on his present tentative views concerning the structure of the Earth with its mantle, core and inner core, and the structure of some of the planets.

Additional members of the European Seismological Commission were then agreed upon from Czechoslovakia, Lebanon, Poland, Rumania, Switzerland (in place of Dr. Wanner, deceased) and the U.S.S.R. Officers elected were: *President*, Prof. P. Caloi (Rome); *Vice-President*, Prof. W. Hiller (Stuttgart); and *Secretary*, Elie Peterschmitt (Strasbourg). The next meeting of the Commission will be held in Utrecht during Whitsuntide 1958.

ERNEST TILLOTSON

RADIO-FREQUENCY PHYSICS

CONFERENCE IN GENEVA

THE 'Colloque A.M.P.E.R.E.' (Atomes et Molécules par Etudes Radio-Electriques) is an organization inspired by Prof. R. Freymann, of the University of Rennes, which was set up soon after the end of the Second World War as a means of ensuring fruitful contact between French research workers interested in any branch of physics that is concerned with the use of radio frequencies (including the microwave region). It was also part of an effort to re-establish scientific research in France, which had suffered very heavily in the War and was quite unfamiliar with the great advances made during the years of hostilities. The subjects at the annual conferences include dielectric constant and loss, magnetic permeability and loss, nuclear magnetic resonance, quadrupole magnetic resonance, paramagnetic resonance, ferromagnetic resonance and associated effects, and microwave spectroscopy. Although primarily a French organization, interest in it has become more general, and it would now be better described as European, although, of course, any scientist is welcome. It has been a matter of considerable pride and satisfaction to the French-speaking members that all the conferences have employed French as the principal language. I feel that this—and the colloquium itself—has helped to give the French renewed confidence and has contributed in some measure to the present renaissance of scientific research in France. It has also made many English-speaking persons appreciate the difficulties which the prevalent use of English at scientific conferences poses for many scientists.

A pattern is being established in which the annual conference is held alternately in France and elsewhere in Europe. This year's conference was held during March 21–23 in the Institute of Physics of the University of Geneva and was attended by some hundred and fifty scientific workers. That for 1957 will be held in St. Malo, Brittany, and will be organized by Prof. R. Freymann.

A special effort was made to widen the appeal of the conference this year in view of the fact that it marks the tenth anniversary of the discovery of nuclear magnetic resonance absorption. General lectures outlining the history and present situation in nuclear magnetic resonance were given by Prof. C. J. Gorter (Leyden), "Vingt années de recherches aux Pays-Bas sur les résonances magnétiques"; Prof. M. Grivet (Paris), "Exposé sur les travaux effectués par l'équipe française de résonance nucléaire"; Prof. L. Giulotto (Pavia), "Exposé sur les travaux récents effectués au Laboratoire de Pavie dans le domaine des temps de relaxation nucléaire"; Prof. R. A. Ogg (Stanford), "Application à la chimie

de la résonance magnétique nucléaire"; and Prof. A. Lösche (Leipzig), "Quelques travaux sur la résonance paramagnétique nucléaire effectués à Leipzig". A lecture by Prof. C. H. Townes (Columbia) on the measurement of time by spectroscopic methods was an apt illustration of the application of many of the ideas and techniques discussed during the conference.

Some fifty papers were presented in six sessions, fairly evenly distributed over the subjects mentioned above and representing contributions from some thirty laboratories. Preprints of almost all the papers were available before the conference; authors were allowed fifteen minutes for presentation of the gist of their papers, and the matter was then thrown open to discussion. As is usual at these conferences the discussions were unusually free and frank and therefore most valuable to all concerned. It is perhaps conducive to a free exchange of views at such a meeting that the discussion itself is not recorded or published.

It is evidently impossible to mention each paper in detail, and I am obliged to pick out the ones which seemed of more than usual interest. The first two sessions on dielectric constant and loss included several papers on measuring techniques. There were also two papers on mixtures, which still present many difficulties, by J. M. Hough and J. A. Reynolds (Hull) and by G. P. de Loor (The Hague). Study of the dielectric properties of hydrogen-bonded liquids (R. Arnoult *et al.* (Lille) and C. Brot (Paris)) continues to produce interesting results. G. Offergeld (Brussels) described dielectric measurements on a series of methacrylate polymers. R. Freymann and his group (Rennes) presented papers on dielectric effects in various solids and particularly in selenium and zinc sulphide, showing the effect on dielectric properties of illumination at 3650 A. They also showed that one of the dielectric absorption regions in solid camphor is in reality due to fenchone impurity.

The third session, on electron resonance of various types, included several papers on free radicals and particularly on DPPH. R. Gabillard (Geneva) and J. Berlande (Paris) described ingenious uses of electron resonance in the control and measurement of magnetic fields in particle accelerators. Measurements on ferrites still attract considerable interest in view of their great technical importance; several papers in the fourth session were concerned with these and in particular with the Faraday effect (F. Mayer, of Grenoble), the behaviour in the resonance region (J. Pauleve, of Grenoble), and the effect of losses (J. Snieder, of The Hague). In the fifth session, J. Winter and J. Brossel (Paris) described electron resonance experiments on optically oriented sodium atoms in which they observed absorption bands at multiples of the usual Larmor frequency. D. Dautreppe and B. Dreyfus (Grenoble) discussed the effect of hydrostatic pressure on the pure quadrupole resonance frequency in *p*-dichlorobenzene; the effect found is readily interpreted in terms of the effect of the pressure on the libration frequency of the molecule in the lattice.

In the last session G. E. G. Hardeman and N. J. Poulis (Leyden) presented new results on the relaxation time for proton magnetic resonance in the antiferromagnetic crystal, hydrated copper chloride, and showed that the relaxation is due to interaction with the copper ions. W. G. Proctor (Basle) described experiments in which the nuclear resonance signal of sodium in sodium chloride is modified by subjecting the sample to ultrasonic radiation at double the Larmor frequency. J. G. Powles (London) discussed the correlation between mechanical, dielectric and nuclear resonance absorption processes in polymers. G. J. Béné, R. Beeler and D. Roux (Geneva) showed that paramagnetic resonance can now be used to measure magnetic field strength down to about 0·05 oersted using metal–ammonia solutions, which have very narrow lines. E. H. Staub (Zurich) has measured the nuclear relaxation time for the rare gas xenon and found a satisfactory explanation in terms of nuclear quadrupole interactions during interatomic collisions.

The success of the conference was due in large measure to the excellent organization of Prof. Extermann, Dr. Béné, Dr. Denis and Miss P. Cottier. A report of the conference is being published in the May issue of the *Archives des Sciences*, and copies can be obtained from the Institut de Physique, Université de Genève, price 25 Swiss francs.

J. G. POWLES

PELAGIC MOLLUSCA: SWIMMERS AND DRIFTERS

THE Malacological Society of London held an open discussion meeting in the rooms of the Linnean Society on the evening of March 14, with Prof. Alastair Graham (University of Reading) in the chair. Invitations had been issued to the staff and students of biological departments, and there was a large attendance, mainly from scientific institutions in or near London, and also from Reading, Oxford and Swansea.

Dr. J. E. Morton (Queen Mary College, London) introduced the subject of pelagic Mollusca with an account of pelagic prosobranchs. Prosobranchs became pelagic in two instances, both of them in the order Mesogastropoda. The three families, together known as the Heteropoda (Atlantidae, Carinariidae and Pterotracheidae), are actively swimming carnivores, and the family Ianthinidae are passive drifters. These two groups illustrate strongly contrasting modes of attaining the pelagic life. In the Heteropoda, the emphasis was upon the lightening and eventual loss of the now unnecessary shell, and the development of lightness and buoyancy, with the tissues becoming jelly-like and the heavy viscera restricted to an insignificant mass. The mantle cavity was fully retained in *Atlanta* and eventually lost in *Pterotrachea.* The foot was transformed into a gracefully undulating fin, and there was considerable speed of movement. Large eyes were developed, with great visual acuity. The shape of the body became fusiform, the higher families losing the planorboid spiral form of *Atlanta.* They are reminiscent of small translucent serpents, moving rapidly, and with the sharp teeth of the buccal mass taking a strong hold of smaller planktonic prey.

The Ianthinidae adopted a pelagic life in a very different way from the Heteropoda. The shell—though lightened—remains of normal size, and forms a globular body whorl with a short apex, vivid violet in colour, floating mouth uppermost. The animal has no special locomotor organs and drifts at the surface, buoyancy being conferred not by jelly-like tissues but by a raft secreted by the foot. In *Ianthina ianthina* this consists of a bubbled mass of air-filled vesicles; in *I. prolongata* and *I. exigua* it is flatter and is used also for the attachment of egg capsules to its under-surface. The teeth of the radula are long and sharp. *Ianthina* feeds on the floating siphonophore *Velella*, attaching itself to the under-surface of the siphonophore and grazing upon its living tissues, until the chitinous float is stripped bare. When feeding on *Velella*, *Ianthina* appears to lose the raft and to make use of the siphonophore not only as food but also to obtain buoyancy and transport. This specialized mode of feeding suggests an origin for the Ianthinidae among those benthic mesogastropods which are sluggish carnivores, grazing on sessile animals, including cœlenterates. *Ianthina* illustrates such a mode of feeding transferred to the pelagic level.

Dr. J. E. Forrest (Queen Mary College, London) directed attention to the interest and importance of the order Opisthobranchiata in considering the development of the free-swimming habit in the Mollusca. The order includes benthic as well as truly pelagic species, while some, essentially creepers, are yet able to adopt a swimming habit at times. It is, therefore, perhaps possible to see something of the steps by which the pelagic habit was acquired. A tendency towards a reduction of the shell characterizes this group and culminates, eventually, in its absence in the gymnosomatous pteropods and throughout the nudibranchs. The foot also has a certain plasticity and is frequently modified by the development of parapodia or wings which, arching upwards on each side, form a cloak enclosing the shell and visceral mass as, for example, in *Aplysia* and *Akera*. In the latter, parapodia are particularly well developed, and by their means the animal can periodically, and notably in the breeding season, perform vigorous and effective swimming movements the significance of which, however, is not clear.

In the Tectibranchiata, both the Bullomorpha and the Aplysiomorpha have, apparently independently, evolved pelagic representatives, the thecosomatous and gymnosomatous pteropods respectively, and of all the gastropods which have taken to this mode of life they are, perhaps, the most specialized. *Limacina*, a primitive thecosome, is in many respects intermediate, sharing benthic and pelagic features although the animal is planktonic. It has a fully coiled shell and visceral mass, swims by means of wings, and is microphagous, but still possesses a pallial ciliary feeding mechanism. The more specialized thecosomes, such as *Cavolinia*, *Creseis* and *Cymbulia*, have a greatly reduced, paper-thin shell which is no longer coiled, and swim by movements of the extensive wings spread out laterally beyond the opening of the shell. A pallial feeding mechanism no longer occurs, and the feeding tracts are limited to the now greatly reduced central part of the foot and, in some genera, the wings as well. These are minute animals, the larger species measuring perhaps 2 cm. in length, and in all their features show a complete adaptation to a pelagic habit.

In contrast, the gymnosomes, also minute, are carnivores preying, it is thought, on the smaller thecosomes. In common with them, they possess wings which serve for locomotion and also help to keep the animal afloat, but in almost all other features they stand apart. The shell is absent, the body cylindrical and the complex buccal apparatus includes series of suckers for grasping the food and paired-hook sacs in relation to the buccal cavity. They have never developed a ciliary feeding mechanism. Although conveniently considered together, the thecosomes and gymnosomes probably represent two independent lines of evolution which parallel each other in certain respects. To place them together in one order, the Pteropoda, is probably an unnatural grouping.

The nudibranchs are more conservative and have given rise to only a few pelagic forms—the rare, transparent, brilliantly luminous phyllirhoids the modifications of which follow less spectacular lines.

Dr. Anna Bidder (Cambridge) spoke of the Cephalopoda, with particular reference to the method of swimming. Jet-propulsion, the basic swimming mechanism of the Cephalopoda, is effected in two ways. In the Nautiloidea, the non-muscular mantle of which lines the living chamber of the external shell, water enters between the overlapping folds of the funnel. Proximal 'circular' muscles provide the necessary expulsive force, and distal longitudinal muscles can be used in steering and are firmly anchored to the shell through the shell muscles. In the Belemnoidea and in all living cephalopods except *Nautilus* the shell is internal or absent. The circular fibres of locomotion constitute the mass of the muscular mantle, the major muscles of the tubular funnel are longitudinal, and both systems are anchored to the guard, phragmacone and pro-ostracum or to their derivatives when present.

Fins, first known as small posterior rounded lobes, may be regarded as stabilizers during forward movement and as assisting in gentle to-and-fro or hovering movements. Fins show a wide variety in shape, size and position; they are missing in incirrate octopods only. The deep web, characteristic of the cirromorph octopods, the Vampyromorpha, and the squid *Histioteuthis* may, Dr. Bidder suggested, serve for medusa-like swimming, especially in the Cirromorpha, the small funnel and reduced mantle aperture of which seem inadequate for locomotion. Chun's figure of "*Opisthoteuthis medusoides*" was suggested by Dr. Bidder as evidence of this type of swimming.

Dr. W. J. Rees (British Museum (Natural History)) discussed the characteristics of deep-sea cephalopods and indicated that very few species have been studied alive and that the available depth records with open nets are too few to permit precise conclusions. Likewise, records from the neighbourhood of oceanic islands are unreliable because of upwelling from deep water. Despite this, the broad picture for squids is comparable with what is known for other groups, especially fish.

Dr. Rees demonstrated that the web and arm membranes (the functions of which were discussed by Dr. Bidder) increase in size in benthic octopods and hinted that bathypelagic octopods like *Amphitretus pelagicus* may have arisen from deep-water benthic forms. *Amphitretus*, with its thick gelatinous outer covering, is the only species of cephalopod known to have 'telescopic' eyes. The most remarkable deep-sea forms, however, are the Vampyromorpha and the Cirromorpha, with their paddle-shaped fins, enormous webs and the tactile cirri on the arms. *Cirrothauma murrayi* in the latter group is very fragile and is the only blind species of cephalopod known.

Epipelagic squids of the upper 500 m. are chiefly transparent larvæ of the Cranchiidae, but deeper-living species at about the threshold of light have large eyes (sometimes accompanied by light organs) and often retain powerful toothed or hooked suckers as in *Taonius pavo*. Species living at still deeper evels have a very varied range of light organs and are deep red to bluish-black in colour. The tentacles may become long and whip-like with minute suckers, as in *Mastigoteuthis* and *Bathyteuthis*. Accompanying these external features there are often reduction of radula and loss of ink sac, with a general degeneration of musculature which is largely replaced by a gelatinous layer. *Heteroteuthis dispar*, with its uminous secretion, often regarded as a deep-water species, is usually captured in the upper 300 m. Dr. Rees's contribution was illustrated with colour transparencies of the various species under consideration.

A short discussion followed, in the course of which Mr. B. B. Boycott (University College, London) suggested that analysis of the variety of fin sizes and shapes shown in the animals described by Dr. Bidder and Dr. Rees can be made in terms of the stability requirements of their differently shaped bodies and arms. He reported observations on *Sepia officinalis* and *Loligo vulgaris*. *Sepia* is slightly lighter than water, and relatively broad and short: the two fins are long, movable, muscular flaps, one on either side of the visceral mass. *Loligo* is slightly heavier than water, and relatively narrow and long: the two fins are triangular flaps confined towards the apex of the visceral mass. In both animals when swimming fast ('giant fibre response'), the fins are shut down against the body. When moving gently, waves pass down the fins corresponding to whether the animal is moving forward, backwards or turning. The major propulsive force in both cases is produced by jets of water from the funnel. If the fins are removed in *Sepia*, manœuvring is not much impaired, though the animal does not maintain its position in the water as well as usual but tends to drift towards the surface. The main defect is that it rolls when moving. The fins therefore give the animal lateral stability during gentle swimming. This is probably true also for *Loligo*; but since the funnel is at one end, the fins probably also serve to keep the apex of the visceral mass up when the animal is going forwards and down when it is going backwards. That this is so is indicated by the fact that the head is higher than the visceral mass when moving forwards and lower during backwards motion.

RECENT FLORISTIC STUDIES: BRAZIL, GUATEMALA AND TANGANYIKA

THE following floristic studies have recently been published.

In the Smithsonian Miscellaneous Collections (126, 1, pp. 1–290, with 128 illustrations; 1955), L. B. Smith has given a comprehensive account of the Bromeliaceae of Brazil, based on long and intensive observations. In preparing this work, the author has taken into account the particular interest of this group from the point of view of vegetative propagation, economic and horticultural uses—the pineapple belongs here—and, in some areas, the need for eliminating bromeliads in effecting the control of malaria. A classification of Brazilian Bromeliaceae made some twenty years ago comprised some five hundred native species; but since then 135 additional species have been discovered, and others are coming to hand. An account is given of the sources of information (herbaria and earlier published work), geographical distribution and origin, and keys to the three sub-families and their genera and species, with line drawings of representative species.

A further contribution to the "Flora of Guatemala", Part II, "Grasses", by J. R. Swallen (with the section on "Bamboos" by F. A. McClure), is published as volume 24, Part II, pp. 1–390, of *Fieldiana*, 1955 (Chicago Natural History Museum). In this treatise, the author includes 120 genera and 455 species, native and introduced. This very considerable number of species is attributed in part to the diverse habitats, from tropical lowlands to sub-alpine meadows, which the territory of Guatemala provides. The largest genera are *Panicum*, *Paspalum* and *Andropogon*, these comprising about one-third of the total grass species. In conformity with the general arrangement of this Flora, the genera and species are set out in alphabetical order. An evident disadvantage of this is that certain closely related genera and species may be widely separated in the text. More than a hundred clear line drawings add to the value of this work.

The extensive hydrobiological survey of Lake Tanganyika, undertaken during 1946–47 under Belgian auspices, has yielded a further report, in which accounts are given, by different authors, of the Characeae, Hepaticae, Pteridophyta and certain families of flowering plants of the Lake region. ("Exploration Hydrobiologique du Lac Tanganika (1946–1947): Résultats Scientifiques." *Inst. Royal des Sci. Nat. de Belgique*, 4, Fasc. 2, pp. 1–82; Brussels, 1955.)

NATIONAL OCEANOGRAPHIC COUNCIL

REPORT FOR 1954–55

THE chief instrument of the National Oceanographic Council is the National Institute of Oceanography at Wormley, near Godalming, and the two main fields of study pursued at the Institute are marine biology (centred about problems concerning the Antarctic whale fisheries) and marine physics (involving mostly studies of surface waves, wind stress, and more recently, storm surges). The annual report for 1954–55, recently issued*, shows that relatively little work is done in marine chemistry and submarine geology. A comparative analysis of publications of the two leading oceanographic institutions in the United States suggests that the scientific programme of the National Institute of Oceanography most nearly resembles that of the Woods Hole (Mass.) Oceanographic Institution. The Scripps Institution, at La Jolla, Calif., places additional emphasis on biology, geology and chemistry, in descending order, and in this sense the Scripps Institution appears to present the most balanced programme. That the National Institute of Oceanography compares so favourably with the American institutions is all the more impressive when one considers that it is about one-third the size of either of them (inasmuch as budget and total number of persons employed are an index of size).

---

* Annual Report of the National Oceanographic Council, 1 April 1954–31 March, 1955. Pp. v+38. (Cambridge: At the University Press, 1956.) 5s net

The work of previous years on the measurement of ocean waves has served the National Institute of Oceanography as a nucleus for an expanding programme in the action of winds upon the sea. Directly following the Second World War, work was confined to the measurement of sea waves, computation of power spectra, and a qualitative interpretation in terms of the ocean-wide distribution of storms as revealed by weather maps. The present annual report shows that the wave studies have expanded in scope; for example, a serious attempt is being made by Dr. M. S. Longuet-Higgins to measure vertical displacement of the water surface and instantaneous atmospheric pressure at the water surface simultaneously—a type of measurement that is essential for developing a clearer physical understanding of the mechanism of wave generation. Dr. Longuet-Higgins has also developed an elegant theory of the statistical properties of a random moving surface—a form of mathematical language particularly suitable for the statement of the properties of the ocean surface and most necessary for a future physical theory of the generation, propagation and dissipation of ocean waves. Also under way are several ingenious programmes for the observation of shallow drift currents due to the wind, studies of natural oscillations and storm surges in large basins such as the North Sea, and preparations for the Institute's part in the coming International Geophysical Year.

To describe in detail each of the studies reported for 1954–55 and to name each investigator would be to reproduce the annual report in substance. My selections or omissions do not imply any evaluation or criticism; they merely reflect varying degrees of personal interest and the necessity for keeping this review brief. However, mention should be made of Dr. J. C. Swallow's newly developed neutrally buoyant float for tracing deep currents in the ocean. One hopes that the new float will lead to a re-awakening of interest in the problem of the general circulation of the ocean, a problem which has lain dormant for about twenty years largely because no adequate means existed for measuring directly the deep-sea circulation. The problem of describing the deep-sea circulation accurately—and independently of present-day hypothetical elements—is of considerable practical importance because so many eyes are cast toward the oceans as a place for the ultimate disposal of wastes from nuclear reactors. It is known that certain seas, like the Black Sea, are virtually stagnant beneath the top hundred metres and that these deep waters might possibly serve as an ideal dumping-ground for large volumes of radioactive wastes, barring a climatic catastrophe and a sudden turnover of bottom water.

The deep waters of all the oceans are isolated from the surface to a much lesser extent. The question then arises as to whether one can tolerate a fairly high level of radioactive waste in the deep ocean water without contaminating the surface. The oceanographer cannot at present give an affirmative answer to this question, but certainly Dr. Swallow's new device is the first glimmer of hope that we shall soon describe deep-sea currents more accurately. Before the War most of the effort of oceanographic institutions was directed toward exploring the large-scale ocean circulation. At present, only about 5 per cent of the publications issuing from the National Institute of Oceanography and from the Scripps Institution of Oceanography concern the general circulation of the ocean. The percentage from the Woods Hole Oceanographic Institution averages somewhat higher, due probably to its proximity to the Gulf Stream. The present paucity of investigation of the really deep sea in Britain and the United States will doubtless be remedied through the stimulus of such new techniques as that of Dr Swallow, because of the increasing pressure for definite information from those concerned with nuclear energy and as a result of theoretical advances in dynamical meteorology.

HENRY STOMMEL

CARNEGIE UNITED KINGDOM TRUST

REPORT FOR 1955

THE forty-second annual report of the Carnegie United Kingdom Trust, covering the year 1955* is of special interest for its review of the quinquennium 1951–55, during which grants totalling £558,495 were paid, and for the statement of policy for the next quinquennium, which is appended. The development of the visual arts scheme, which was a new venture during 1951–55, has been most encouraging, and a larger allocation is contemplated in the new quinquennium. New life has been infused into many small museums, which have been converted into lively centres of culture and of education through recreation, and the Trust has joined with the Museums Association in urging on the Government the need for State aid to the national museums as the only real hope of retrieving a serious situation. In the field of community services the largest single determining factor during the past five years has been the Trust's awareness that problems of material want have given place to problems of personal, family and community relations, and both the Community Services Committee and the Education Committee have been concerned with research into the causes of social problems arising in families, into the effectiveness of new techniques for dealing with family problems, the development of family casework agencies, experimental projects for restoring problem families to health, demonstration homes for delinquent boys and for the homeless sick, re-training of social workers and counsellors and the development of a new university course designed to produce general practitioners in social work.

The rehousing of the Scottish Central Library and several other building projects accounted for half the Trust's expenditure during the quinquennium, but the passing of legislation which brought the Scottish Central Library, during 1955, into financial independence of the Trust completed the Trust's historic contribution towards the development of the public library system. Building projects which the Trust has recently supported are used for housing its beneficiaries or for accommodating services it wishes to support, and have been designed to meet needs which have not so far been comprehended in the provisions of the Welfare State; the Trust also emphasizes its intention to keep a proper balance between rescue work and amenity.

The statement of policy for the quinquennium 1956–60 points out that the Trust prefers to conentrate its resources in limited fields where it can make an effective contribution to development, and hat in selecting projects it distinguishes two main ypes : development work which is carried out over he country as a whole ; and experiment or investigation, which may be carried out on a local basis but with the hope that the results may be of general application and usefulness. The main branches of activity for which part of the Trust's funds have been allocated for this current quinquennium are six n number : the encouragement of amateur music and drama activities ; the encouragement of the practice of the visual arts by amateurs through grants towards the cost of occasional expert tuition for groups of three or more art clubs ; the development of the local museum service, in co-operation with the Museums Association ; the upport of the National Councils of Social Service ; the support of the efforts of the Family Welfare Association and Family Service Units to improve the quality of family life ; and projects selected by the Trust to encourage outdoor group activities. In this connexion, the Trust hopes to contribute to the resources of a national park or a national forest park and to increase the value of the parks, as well as to assist field-work in the biological sciences and archæology, and a sum of £50,000 has been provisionally earmarked for expenditure on such schemes.

---

* Carnegie United Kingdom Trust. Forty-second Annual Report 1955. Pp. viii+92 (9 plates). (Dunfermline: Carnegie United Kingdom Trust, 1956.)

Reviewing the work in 1955, the report records the award of grants to sixteen museums and of exceptional grants, each of £1,000, to the Highland Folk Life Museum at Kingussie and to enable the Bowes Museum at Barnard Castle to remain open. Grants were also given to students and to museum officials to enable them to widen their professional and technical knowledge. During the past ten years nearly a hundred museums have been assisted to eorganize their basic layout, and a sum of £50,000 has been allocated for such purposes for the 1956–60 quinquennium. Support of the visual arts is being continued on the usual lines, and £15,000 has been allocated for the purpose.

The report expresses the hope that the plans which the Executive Committees of the National Councils of Social Service are now considering for increasing their free income will soon produce results commensurate with the public services it performs, but meanwhile the Trust is increasing to £8,600 its total contribution for this service in the quinquennium. The Family Welfare Association's general-purpose grant has been renewed at £2,000 for 1956, £1,750 for 1957 and £1,500 for each of the following three years, and £10,000 has been set aside for the further development of Family Service Units, of which there are now eleven established on a permanent basis in reasonably well-equipped centres, with warm support from the local authorities. A grant of £5,000 over five years was made to the Liverpool Research Service Society for the purchase and equipment of sub-standard working-class houses for the accommodation and training of homeless families, and satisfactory progress is reported. A final grant of £1,500 was made for the blind-deaf machine, 'Arcaid', to be administered by the National Institute for the Deaf. The first group of twenty-five students completed, in the summer of 1955, their four years course of training as social workers at the London School of Economics, to which the Trust made a grant of £20,000 in 1953, and a second group started in October 1955. The Trust has also agreed to finance for five years, at a cost of £25,000, the Bristol Social Project which has as its main objects the investigation of stresses and strains in a developing community and their practical prevention and control and the education of the community to a higher level of responsibility.

THE GOLGI APPARATUS AND THE ELECTRON MICROSCOPE

By Prof. J. BRONTË GATENBY and R. G. LUTFY*
Trinity College, Dublin

IN 1951, A. J. Dalton[1] first made satisfactory electron pictures of the Golgi apparatus. In 1953, Dalton and Felix[2] published an important memoir on the Golgi apparatus of the epithelial cells of the epididymis and duodenum of the mouse. Those who previously had at their disposal only the light microscope found much food for thought in this work. Dalton and Felix described the small granules (or Dalton–Felix bodies) which probably always are associated with the Golgi apparatus. They showed that the net type of Golgi apparatus found in the epididymis really consists of a series of hollow tubes, in section much thicker on one side than the other, their cavity filled by more or less compressed vacuoles in chain form (Fig. 1). The wall of these tubes consisted of double lamellæ sweeping along the length of the Golgi apparatus. Their work agreed in broad details with the previous light microscope study by Nassonow[3]. Outside the Golgi apparatus were found comparatively large bodies which stain with neutral red and methylene blue, probably of a nutrient nature (lipochondria ?). The double membranes have also been described by French and Swedish workers, of whom Johannes Rhodin[4] may be mentioned for his study of the cells of the convoluted tubes of the kidney.

None of this work, however, answered completely some important questions which have arisen in recent years. Three of these are the supposed relation between the commonly occurring dictyosome of invertebrate somatic cells, and of all animal male germ cells, and the Golgi apparatus of higher vertebrate neurones ; another, the supposed relation between secreted material and the Golgi apparatus. Work on the latter with special reference to the pancreas has been recently dealt with by one of us[5] ; a paper by Sjostrand and Hanzon[6] not accessible to us should be consulted in addition. Another puzzling question was the nature of the so-called chromophobe part of the dictyosome, which usually had been assumed to be a coagulable material, which formed a greyish inner mass, as observed in osmium preparations under the light microscope. If this mass was an intrinsic coagulable part of the dictyosome and not vacuolar and watery, it became difficult to homologize the dictyosome and the conventional vertebrate canalicular apparatus of Golgi as conceived by Cajal, and generally speaking proved correct by Dalton and Felix[2].

---

* Ein Shams University, Cairo.

It is difficult to make satisfactory line drawings of electron photographs because of their fine ground detail. Figs. 1–6 are of the epididymis[2], the cricket spermatid (Beams, Tahmisian, Devine and Anderson, unpublished), the *Stronglycentrotus* egg (Afzelius, unpublished), the sponge *Grantia*[7], a human breast cancer cell[8] and the kidney tubule cell[4]. Now in no case does the cavity of the Golgi apparatus (*V*) show any coagulum. This would appear immediately to rule out the older view that secreted material appears inside Golgi canals or vacuoles. At least one convincing exception to this is the Golgi spaces of the bile ducts in liver cells[8]. The contractile vacuole (cortex and vacuoles) of the freshwater sponge and Protozoa does not stain vitally in neutral red, and so far as we know neither does any one of the included spaces (*V*) in Figs. 1–6.

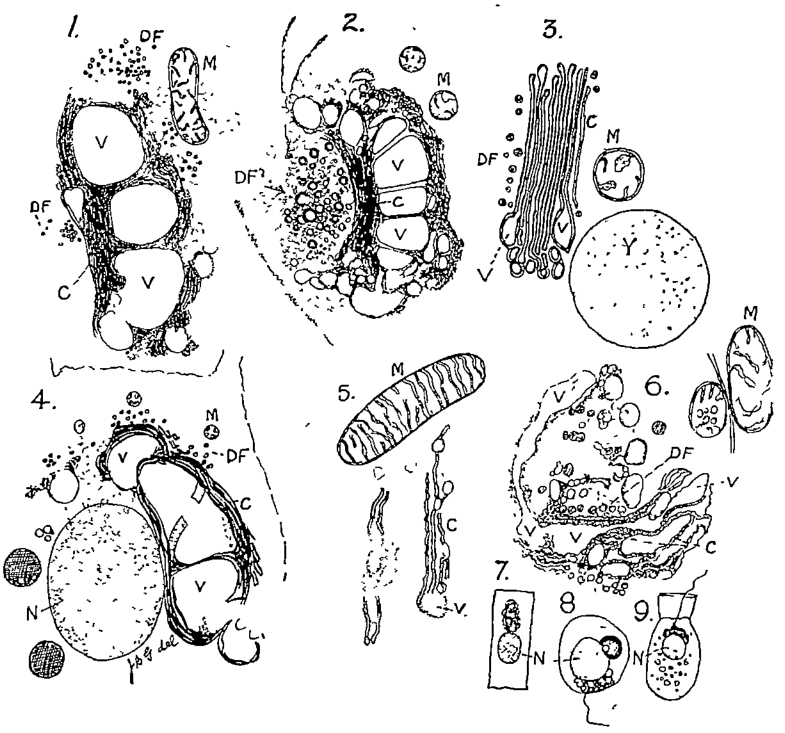

Fig. 1. Part of the Golgi net of the epididymis (Dalton and Felix). Fig. 2. Spermatid dictyosome of the cricket, *Nemobius* (Beams, Tahmisian, Devine and Anderson). Fig. 3. Dictyosome of oocyte of *Stronglycentrotus* (Afzelius). Fig 4. Dictyosome of *Grantia* choanocyte (Gatenby, Dalton and Felix). Fig. 5. Convoluted tubule cell of rabbit (Rhodin). Fig. 6. Human breast cancer, cell of a metastasis (Haguenau and Bernard). Fig. 7. Type vertebrate epithelial cell showing net apparatus above nucleus; Fig. 1 refers to part of net. Fig. 8. Insect spermatid with dictyosome on right of nucleus; refers to Fig. 2. Fig. 9. Sponge choanocyte with dictyosome; refers to Fig. 4. Fig. 6 is a cross-section of entire Golgi apparatus with elongate canal (cavern). Figs. 7–9 are from cells seen living with phase contrast

M, mitochondrion; *C*, cortical membranes; *DF*, Dalton–Felix bodies; *Y*, yolk sphere; *N*, nucleus; *V*, vacuole, cavern, canal

Turning now to the very interesting electron photograph of the cricket (*Nemobius*) spermatid dictyosome, Fig. 2, we have the usual arrangements of an included chain of vacuoles, a cortex of double membranes different and spongy on the right side of the figure, and on the extreme left a group of granules varying in size from the usual Dalton–Felix type to larger vesicles (micro-vesicles); this then is a dictyosome with four parts. Beams *et al.* consider the micro-vesicles to be pro-acrosomic, and we agree. In other photographs obtained by Beams and his group, this spherical area of micro-vesicles is found to have become surrounded by a wall, and is then undoubtedly the acrosome just before its adherence to the spermatid nucleus. At this stage the large, presumably watery vacuoles (*V*) included in Fig. 2 have almost completely disappeared. In the spermatocyte, Beams *et al.* have shown that prior to the maturation divisions the vacuoles (*V*) are ready and developed. Thus part of the preparation for the final stages of acrosome secretion appears to be the accumulation of water in the dictyosomes. It is to be hoped that further information on this point will be obtained by Beams's group. It would now appear that the site of acrosome secretion primarily is at the outside, and not the inside, of the dictyosome, and that the current idea that the dictyosome actually secretes the acrosome may need to be modified. Moreover, it is now apparently not possible to believe that the dictyosome is dehydrating the forming acrosome[5].

The electron photograph by Afzelius of the echinoderm dictyosome is interesting because the spaces which presumably could later swell up to form the chain of vacuoles clearly appear not within the double membrane, but between pairs of membranes (Fig. 3). The same appearance is found in Rhodin's examples of kidney tubule cells, in Beams's materia and in Lacy's pictures of the dictyosomes of *Patella vulgata* neurones (unpublished work).

In the past there have been differences of opinion as to the morphology of intra-cellular bodies, living or fixed, and studied with the light microscope. The electron microscopists use much thinner sections, and their results are not always easy to interpret. This certainly applies to the three distinct parts of the *Nemobius* dictyosome (plus acrosome) of Beams *et al.* (Fig. 2).

The following conclusions seem possible at this stage of work. (*a*) The cavities of the Golgi apparatus do not become filled with secretion. (*b*) The chromophile part of the Golgi apparatus is the double membranes or cortical substance, whereas the chromophobe part appears to be a system of caverns (Cajal) presumably filled with water. (*c*) Secretion takes place near but not in the Golgi apparatus, as if from the ground cytoplasm or from the mitochondria (pancreas), or perhaps from detached parts of the double membranes (Dalton–Felix bodies). (*d*) Neutral red used vitally does not initially stain the cortical substance or the chromophobe (vacuolar part), but does stain either the early secretion or mitochondria possibly when changing into secretion[9]. (*e*) The arrangement of the dictyosome into cortical substance and Dalton–Felix or small granules is the same probably from Protozoa, and certainly from sponges, up to mammalian cells. A single vacuole or chains of watery vacuoles may develop between the pairs of cortical membranes, but are not always present. These spaces apparently represent the cavity of the protozoan contractile vacuole. (*f*) The Golgi apparatus of the neurone is like that of Rhodin's kidney tubule cells (Fig. 5) and Haguenau and Bernard's cancer cell (Fig. 6), that is, a series of very long double lamellated membranes, with or without enclosed and neighbouring chains of caverns and vacuoles[9,10].

The arthropod and molluscan dictyosomes in a testis viewed with the light microscope are always approximately the same size at a given stage (Fig. 8). As might therefore be expected, the number of double membranes (that is, paired membranes) seems fairly constant for the invertebrate dictyosome, there being about twelve in both *Helix aspersa* and *Lumbricus terrestris* spermatids[10], 8–10 in the *Strongylocentrotus* oocyte dictyosomes (Afzelius, unpublished), and about 6–8 in the *Nemobius* spermatid dictyosome (Beams *et al.*). P. Grassé, N. Carasso and P. Favard[11] have published pictures of the *Discoglossus pictus* spermatid dictyosome with only four very clear membranes; in the rat neurones (Palay and Palade[9]) four or five pairs are present. There are about 6–8 in the late acrosome stage in the mouse spermatid[10]. In the mouse kidney tubule[4] there are membranes consisting of 2, 3 or 4 pairs. The cerebral cortex neurones of the mouse, in the one photograph we have seen, have similar 'strings' of 2–6 pairs of membranes[10]. In the pictures of *Lumbricus* and *Helix*, the membranes are piled in a pyramidal shape, the conventional curved outline of the living dictyosome under phase being brought about by the graduated lengths of the individual pairs[10]. Where vacuoles exist between members of pairs, the count is often difficult to make, especially where the lamellæ are more delicate and thinner in section, as in *Nemobius* (Beams *et al.*).

On the question of the nature of silver and osmium impregnation of the Golgi apparatus, which is remarkably specific, despite what has been written in controversy by some authors, it seems obvious that both the metallic and hæmatoxylin methods depend on a reaction on or in this system of close membranes.

Finally there is one question which cytologists who have no electron microscope are bound to ask. Is it worth while going on with the light microscope in any of its present various forms? After having studied electron photographs made recently by various workers, it has been concluded that the light microscope is useful for finding problems to be investigated properly by the electron microscope.

We thank Drs. Dalton, Felix, Afzelius, Lacy and Haguenau and Prof. Beams and his associates for generously sending some of their unpublished work with comments for our study. It is possible that these workers may not agree with some of our observations on the information they have been able to supply in this field.

HISTOCHEMISTRY OF MUCOPOLYSACCHARIDE-LIKE SUBSTANCES AND ALKALINE PHOSPHATASE IN MADREPORARIA

By THOMAS GOREAU

Physiology Department, University College of the West Indies, Jamaica

MUCOPOLYSACCHARIDE-LIKE compounds and non-specific phospho-monoesterases (phosphatase)[1] have been found to occur in Madreporaria. Histochemical investigations were undertaken to localize these substances in the polyps of thirty-two species of corals belonging to twelve families. All but eight of the species were tropical reef-builders collected in Jamaica. Of the non-reef-building corals, two were collected in Jamaica, three in British waters and three near Naples, Italy.

(1) *Epidermis:* The columnar supporting cells were strongly positive to phosphatase and periodic acid–Schiff tests, and orthochromatic with respect to toluidin blue. In the Dendrophylliidae, the epidermis contained little or no phosphatase activity. The mucus glands were phosphatase and periodic acid–Schiff negative but possessed an intense purplish-red γ-metachromasia. The granular glands in the stomodeal epithelium were phosphatase negative, positive to the periodic acid–Schiff test and displayed an intense purplish-black β-metachromasia. Nematocysts of the spirocyst variety were negative to phosphatase tests, faintly positive to the periodic acid–Schiff test, and were virtually unstained with toluidin blue.

(2) *Mesoglea:* This was phosphatase-negative, orthochromatic with toluidin blue and strongly stained by the periodic acid–Schiff test. The last reaction was localized both in the fibrillæ and the acellular ground substance.

(3) *Gastroderm:* The epithelial cells showed very high alkaline phosphatase activity. They also stained strongly with periodic acid–Schiff and exhibited orthochromasia with toluidin blue. In the cytoplasm of the mature ova, phosphatase and periodic acid–Schiff activities were concentrated in a narrow zone around the yolk droplets. The septal filaments and lateral mesenterial lobes, the 'absorptive zone' of Yonge and Nicholls[2], possessed higher phosphatase and periodic acid–Schiff activities than any other structure in the coral polyp. The phosphatase-negative zooxanthellæ were invariably surrounded by a strongly phosphatase-positive gastrodermal reticulum in intimate contact with the algal

surface. The large nematocysts and hyaline glands of the septal filaments were phosphatase-negative and stained only weakly with periodic acid–Schiff. None of these structures displayed metachromasia. Contractile tissue, especially the fibres of the septal retractor muscle, exhibited high phosphatase activity but stained very little with periodic acid–Schiff. The staining properties of the mucus and granular glands in the gastrodermis were the same as those for similar glands of the epidermis.

The material of the mesoglea, epidermis and gastrodermis reactive to periodic acid–Schiff showed the histochemical properties of neutral mucopolysaccharide in that it was non-metachromatic, resistant to amylase and unaffected by peptic and tryptic digestion. The material in the granular glands reactive to periodic acid–Schiff is probably a kind of acid mucopolysaccharide due to its strong metachromasia. In all cases, the periodic acid–Schiff reaction could be blocked by acetylation[3]. The pyrenoids of the zooxanthellae contained an amylase-soluble material that reacted strongly with periodic acid–Schiff. Droplets of a similar material were also observed in the lateral lobes at the base of the septal filaments. These were found only, in the presence of disintegrating zooxanthellæ in process of extrusion; hence it was concluded that the amylase-soluble material reacting with periodic acid–Schiff found at this site was not glycogen but amyloid liberated by broken-up zooxanthellæ, It is probable that the compound identified by Hosoi[4] as glycogen in *Fungia actiniformis*, a coral containing zooxanthellæ, was in fact amyloid of algal origin.

The metachromatic substances in mucus have been provisionally identified as simple acid mucopolysaccharides; but the nature of the acid mucopolysaccharide-like material in the granular glands is unknown. Preliminary studies indicate that the granular glands discharge during feeding, and that the mucus extruded at this time contains acid phosphatase.

One of the striking results of this investigation is the one-way correlation between the presence of extranuclear alkaline phosphatase and the distribution of a neutral mucopolysaccharide-like material in coral. Moog and Wenger[5] found a similar relationship in a wide variety of invertebrate and vertebrate tissues. They suggested that the mucopolysaccharide associated with phosphatase forms part of a cytoskeleton upon which enzymes may be attached in specific ways to provide suitable conditions for their activities. The localization of the phosphatase–mucopolysaccharide complex at epithelial and other selectively active surfaces in corals indicates that this enzyme may be connected with active transport. The phosphatase in the gastroderm is presumably related to food absorption; but the presence of the enzyme in the epidermis is enigmatic. It is suggested (1) that the enzyme may be concerned with flagellar movement, (2) that it may play a part in the formation and extrusion of mucus, and (3) that absorption of food and other substances may occur directly through the epidermis. The last postulate has received some support from two separate lines of evidence. It is a well-known fact that some faviid and mussid reef corals[6] can perform extracœlenteric digestion by means of septal filaments extruded through temporary openings in the edge zone of the cœnosarc. Thus, the possibility exists that direct epidermal food absorption may occur. Electron micrograph studies have shown that the free border of the supporting cells has closely spaced filiform processes which may be an adaptation for more efficient absorption of substances from the external medium[7].

Thanks are due to the Challenger Society, the Browne Fund of the Royal Society, and the British Association for support of various phases of this work, which was part of a Ph.D. thesis presented to Yale University. A detailed report of the histochemical findings will be published elsewhere.

MEASUREMENT OF THE THICKNESS OF THIN FILMS BY MULTIPLE-BEAM INTERFERENCE

By C. WEAVER and P. BENJAMIN

Department of Natural Philosophy, Royal Technical College, Glasgow

THE multiple-beam interference method for the measurement of the thickness of thin metallic films developed by Tolansky[1] is now a well-established technique. The film, the thickness of which is to be measured, is deposited on a substrate, part of which is covered to give a sharp edge to the film. An opaque metallic reflecting layer is then deposited over the edge of the film. The step in this overlayer is measured by using it as one surface of an interferometer and viewing the multiple-beam fringe system in reflexion. Provided that the overlayer assumes the exact contour of the surface, this step-height will give the thickness of the film underneath.

Tolansky has given adequate evidence that silver fulfils the necessary requirements both in its high reflectivity and its ability to contour the surface. Some workers have tried metals other than silver using fringes of equal thickness[2,3] and fringes of equal chromatic order[4]. In both fringe systems the displacement of the fringes at the discontinuity caused by the step-edge gives the height of the step in the opaque layer. However, Avery[2] has shown that the thickness of a silver film as measured by multiple-beam interference may vary considerably with the metal used for the overlayer. It was found that the value for the thickness of a silver film was 25 per cent greater when measured using a chromium overlayer than the thickness when measured with a ilver overlayer. Avery explained this discrepancy by considering the silver film to have an aggregated tructure[5]. He suggested that atoms of silver would nter the interstices of a silver film more easily than atoms of chromium, and that this would lead to a packing-in' effect for silver on silver but not for hromium on silver. Another explanation for this iscrepancy was put forward by Scott, McLauchlin and Sennett[4]. They suggested that the structure of he chromium overlayer adjacent to the substrate might be less aggregated than that of the silver film ; but no further experiments were carried out to check he results of Avery.

The occurrence of this discrepancy was not conirmed by Heavens[3]. No evidence of 'packing-in' of he atoms of the overlayer material into the intertices of the film was observed. This disagreement may be due to the experimental conditions employed by each worker, and the lack of these details in the work of Avery makes comparison of the results very difficult.

Experiments have been carried out in this Department on the measurement of the thickness of thin ilver films, using both silver and chromium as the overlayer material. A standard experimental proedure was adopted for the deposition of these films, which were evaporated on to selected glass microcope slides. Fig. 1 shows the position on the subtrate of the silver film (W), and the overlayer films f silver (X) and chromium (Y). These three films were deposited in succession without admission of air between evaporations. A mechanical device was used to arrange the slide normally above each source n turn, at a distance of 30 cm. Assuming a point ource, the maximum possible variation in thickness ver the whole surface would not exceed 1 per cent. Since the silver film is symmetrically placed with espect to the silver source, the thicknesses at the wo ends should be identical, and this was confirmed within experimental error. The slide was cleaned with 'Teepol', hydrogen peroxide (20 vol.), dried with cotton wool, and polished with lens-cleaning issue. The surface was finally cleaned electrically *n vacuo*. The films were deposited at a pressure of 0^{-4}–10^{-5} mm. mercury. In view of its marked effect n the structure of thin metallic films[6], the rate of vaporation was considered an important experimental condition. Silver films were deposited at vaporation-rates between 1 and 60 A./sec. approximately. In each case the rates of evaporation of the ilver and chromium overlayer films were kept contant at approximately 20 A./sec. and 3 A./sec., espectively. The thicknesses of the silver films were measured by multiple-beam interference fringes of qual thickness viewed in reflexion.

The results of these investigations are shown in Table 1. They indicate that when the chromium overlayer is opaque, then there is no discrepancy in the thickness of the silver film as measured by the two different overlayers. However, when the chromium overlayer is not opaque, then a discrepancy of the type found by Avery occurs. The variation of the rate of evaporation of the silver film appears to have no effect on the results. The first two tests in Table 1 are with a non-opaque chromium overlayer, whereas the remaining tests are with opaque overlayers. The discrepancy in the thickness of the silver film as measured by X and Y is expressed as a percentage of X.

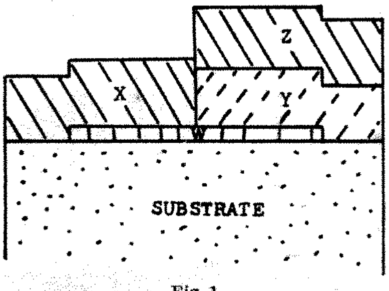

Fig. 1

Table 1

Thickness by X (A.)	Thickness by Y (A.)	Thickness by Z (A.)	Discrepancy $\frac{Y-X}{X} \times 100$	Discrepancy $\frac{Z-X}{X} \times 100$	Rate of evaporation (A./sec.)
337	395	326	17	3	28
461	562	454	22	2	22
203	215	216	6	6	11
245	262	240	7	2	3
456	466	427	2	6	35
577	620	613	7	6	16
939	924	958	2	2	57

Schulz and Scheibner[7] have shown that when a beam of light strikes a metal film at normal incidence, the phase change at reflexion can be related to the thickness of the film. This phase change becomes constant at a certain film thickness, in the case of silver at 500 A. It can be assumed that there is a similar thickness for chromium, and for films below this critical thickness the phase change will be affected by the underlying film or substrate. The discrepancy in the thickness measurements when a non-opaque chromium layer is used may then be caused by a difference in the phase change at reflexion on the two sides of the step-edge since the underlying substances are different. That is, the fringe displacement at the step-edge would consist of the displacement due to the thickness of the silver film plus a displacement due to a difference in phase change.

This proved to be the case. An opaque silver layer (Z in Fig. 1) was deposited on the chromium overlayer ; when the step in this layer was measured, a thickness for the silver film (W) was obtained which agreed with that as measured by the silver overlayer (X), as shown by the first two sets of results. It is concluded that the disappearance of the discrepancy after this final evaporation is due to the elimination of the difference in phase change. This conclusion is supported by the results of tests with an opaque chromium overlayer. There is then no change in the measured thickness value when the silver layer (Z) is deposited on the chromium. The measured height of the step in this layer is in good agreement with the values given by the silver and chromium overlayers X and Y.

The investigation is being continued to determine the critical thickness of chromium and the variation of phase change at reflexion with thickness.

One of us (P. B.) wishes to thank Metropolitan Vickers Electrical Co., Ltd., for the provision of a postgraduate scholarship to undertake this work.

Bone treated with Ethylenediamine as a Successful Foundation Material in Cross-Species Bone Grafts

THE optimal bone graft is one which is most readily: (1) accepted with least reaction, (2) incorporated in callus formation, (3) vascularized with subsequent mineralization, and (4) absorbed (remodelled) by the host. Assuming that the constituents of bone which cause failure are contained in the organic fraction (antigens, fats, mucopolysaccharides, etc.), its removal would allow host acceptance of foreign bone. The remaining inorganic matrix might then be suitable for surgical prosthesis in situations where 'banked' bone is now required. The use of such inorganic bone transplants would, in addition, alleviate the present problems of procuring, storing and supplying whole bone.

Preliminary studies will be reported in which the inorganic matrix of heterologous bone prepared by ethylenediamine extraction was transplanted successfully. It is generally conceded that fresh autogenous bone is optimal for bone grafting. However, conditions do occur which make its use unfeasible. This would be particularly true in a national emergency. It is obviously desirable to have readily available a supply of bone graft material.

Past methods for removal of the organic fraction, which would include any antigenic constituents, have so altered the bone that it differed in composition and/or structure from that of the original bone[1-3]. Recently, Williams and Irvine[1], Peckham and Losee[4], and Singer and Armstrong[5], using ethylenediamine as the organic extractant, removed the organic material of bone with little or no change in the cation or anion composition or the X-ray diffraction powder pattern of the residue. Even the carbonate fraction, which is rather easily lost, apparently remains intact.

Other factors being equal, the speed with which acceptance, revascularization, absorption and perivascular new bone formation take place in a bone graft depends upon the ease with which the osteogenic tissues of the host can penetrate and gain attachment to the graft. With the removal of the organic constituents, bone attains an enormously increased free surface area immediately available without the need for biological debridiment (100 sq.m. per gm.)[6].

The bone used in the present work was extracted in a Soxhlet apparatus with a mixture of 14 ml. triple-distilled water and 86 ml. ethylenediamine (95–100 per cent, Eastman) for 48 hr., followed by absolute alcohol for 4 hr. (5–7 gm. bone). The latter treatment assures removal of any residual ethylenediamine, ethylenediamine carbonate, water, fat and an apparent hæmatin complex resulting from the action of ethylenediamine on red blood cells. The relatively low temperature (90–95° within the bone) required to distil the ethylenediamine results in minimal alteration in composition and structure of the inorganic matrix. After extraction, the prepare bone has a nitrogen content of less than 0·4 pe cent, is very white, apparently bacteriologicall sterile, and retains its form. It can, however, b readily shaped with a scalpel. The treated bone ca also be sterilized by boiling or autoclaving withou change in the nitrogen, calcium, phosphate, or as composition.

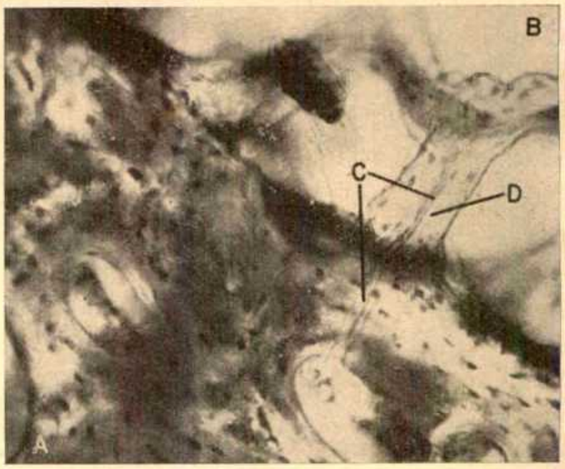

Fig. 1. Histological section of nine-week graft (hæmatoxylin and eosin). Section 100μ thick of bone demineralized with ethylenediamine-tetraacetic acid. Host bone (*A*) supplying blood vessel (*C*) for perivascular new bone formation (*D*) in "ED bone" graft (*B*). Notice vital bone cells in new bone (*D*)

Cortical defects (20 mm. × 5 mm.) were made i the shaft of the dog's tibia and filled with inla grafts of rat femur and bovine cortical femoral bon treated with ethylenediamine. Weekly radiograph were taken and intraperitoneal injections of alizari red *S*, a dye having an affinity for new bone growth were given. Six dogs received rat femoral bone graft and four dogs received bovine femoral cortical strip as donor material. The rat bone grafts were in plac six weeks and the bovine bone grafts nine weeks Gross and histological evaluation of the graft including microradiography[7] indicated apparent acceptance in all cases. A significant amount of reactiv bone formation was clearly demonstrated by th presence of alizarin red *S* at each graft site. Al grafts were covered with and included in callu formation. There was no evidence of foreign bod reaction nor sequestration. Repair was carried ou by an active invasion of blood vessels, connectiv tissue, and tissue fluids from the host into the space of the grafted bone formerly occupied by organi material (which represents about two-thirds of it original volume[8]). Almost complete revascularizatio was noted in the graft of treated bone as early a six weeks following implantation. Extensive absorption of the mineral elements of the graft occurre without the presence of osteoclasts. Absorptio was followed by a significant degree of perivascula new bone formation (Fig. 1).

If further study substantiates preliminary findings it appears that unlimited sources are immediatel available for the preparation and storing of steril supplies of bone-graft material.

Two-Dimensional Electrophoresis of Serum Proteins

A METHOD of zone electrophoresis in starch gels has recently been described by one of us[1]. The high degree of resolution obtained with this method when applied to serum appears to be due to the use of a supporting medium the pore size of which approaches the molecular dimensions of some of the proteins involved, so that resolution by molecular sizes is superimposed on resolution by free solution mobilities. Consequently the starch-gel electrophoretic separations result from a qualitatively different process from that involved in free-solution electrophoresis. A combination of the two electrophoretic processes at right-angles should therefore give a much greater degree of resolution than is possible with either separately. Such a two-dimensional electrophoretic system has been tested by us, using electrophoresis on filter paper as a close approximation to that occurring in free solution. The present communication illustrates the type of result which can be obtained; a detailed description of the method will be published later.

The first electrophoresis is carried out on a 5-mm. wide strip of Schleicher and Schüll 589 *YD* filter paper using a buffer of *p*H 8·55 (Poulik, M. D., unpublished work) and of ionic strength approximately 0·1, prepared from Michaelis stock solution[2] by the addition of hydrochloric acid. The strip with the serum proteins separated according to their free-solution mobilities is then inserted into a starch gel 12 cm. in width, and a second electrophoresis is carried out at right-angles to the first. The gel is made and stained in the way described in the previous publication[1] and the starch-gel electrophoretic conditions are the same as described there for serum protein separations.

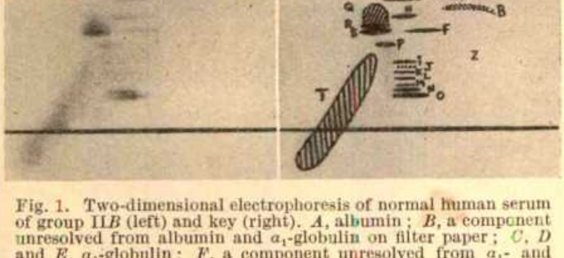

Fig. 1. Two-dimensional electrophoresis of normal human serum of group II*B* (left) and key (right). *A*, albumin; *B*, a component unresolved from albumin and α_1-globulin on filter paper; *C*, *D* and *E*, α_1-globulin; *F*, a component unresolved from α_1- and α_2-globulins on filter paper; *G* to *O*, α_2-globulin; *P*, a component unresolved from α_2- and β-globulins on filter paper; *Q*, *R* and *S*, β-globulin; *T*, γ-globulin. *Z* is a shadow introduced in the photographing and should be disregarded. The black line across the photograph indicates the position of insertion of the filter-paper strip

A photograph and explanatory diagram of the results obtained with 0·01 ml. of normal human serum of group II*B* [1,3] are shown in Fig. 1. More than fifteen resolved components can be seen even at the present stage of development of the method. The full significance of these results will be discussed in the later paper. However, we should like to point out that, in addition to an improvement in the resolutions which can be obtained, information on the distribution of molecular sizes in the various electrophoretic fractions results from this new method. For example, the α_2-globulin fraction obtained in the first filter-paper electrophoresis is resolved into more than six components by the second starch-gel electrophoresis. This indicates that there are more than six molecular size-groups present in the α_2-globulin of serum from the individual here concerned.

Fractionation of Deoxyribonucleic Acid by Physical Procedures

THE use of an ultra-violet light absorption system for determining the sedimentation characteristics of deoxyribonucleic acid at low concentrations has already been described[1]. Further work has shown that the sedimenting boundary is stable and that the measurements can be made at concentrations of deoxyribonucleic acid as low as 10^{-5} gm./ml. It has been found for five preparations from calf thymus which have been studied[2] that the distributions of sedimentation constants at infinite dilution (for solutions in 0·2 *M* sodium chloride) covered a range from $S_0 = 10$ to at least $S_0 = 40$, and that the individual distributions differed significantly, the average sedimentation constant varying from $S_0 = 23$ to $S_0 = 29$.

To confirm that this observed distribution was due to a true heterogeneity, a solution of deoxyribonucleic acid (0·007 per cent) in 0·2 *M* sodium chloride was centrifuged in a bucket rotor for a sufficiently long time to remove all the material with $S > 20$. The supernatant was allowed to stand for 24 hr. at 4° C. and the distribution of the sedimentation coefficients was then determined. It was found that the average sedimentation coefficient was reduced from $S = 19$ to $S = 14$, and only 4 per cent of the deoxyribonucleic acid had a sedimentation coefficient greater than $S = 20$ (Fig. 1*a*). This shows that the observed distribution of sedimentation coefficients is real and also that there is no tendency for the particles of low sedimentation coefficients to aggregate on standing.

In order to determine to what extent variations in the distribution can arise during the preparative procedure, curves for the distribution of the sedimentation coefficients for the deoxyribonucleic acid in the nucleoprotein and at various stages during the removal of protein have been determined by carrying out experiments in 2·5 *M* sodium chloride, a salt concentration at which the dissociation into deoxy-

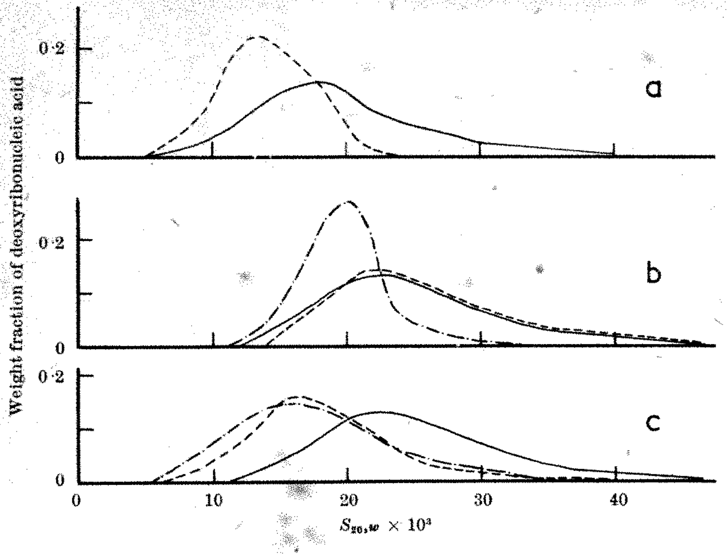

Fig. 1. Normalized distribution curves of sedimentation coefficient for deoxyribonucleic acid (DNA). The area under each curve is the same. (*a*) ———, 0·007 per cent DNA; – – – – –, DNA fraction obtained after centrifuging to remove material with $S > 20$.
(*b*) ———, DNA in nucleoprotein; – – – – –, DNA prepared by the detergent method; —·—·—, DNA prepared using amyl alcohol and chloroform.
(*c*) ———, DNA in nucleoprotein gel; —·—·—, DNA in soluble component of nucleoprotein; – – – – –, DNA in nucleoprotein gel after gel has been standing for 10 days at 4° C.

ribonucleic acid and protein is substantially complete[3]. These distributions were then compared with that observed for the final product of deoxyribonucleic acid after drying in alcohol and acetone and redissolving. Using the method of Kay *et al.*[4], in which protein is removed using the detergent dodecyl sulphate, it was found that no marked change of the distribution curve occurred at any stage during the preparation. The distribution of sedimentation coefficients for the deoxyribonucleic acid in the nucleoprotein and for the final product is shown in Fig. 1*b*. On the other hand, when deoxyribonucleic acid is prepared by the Sevag procedure[5], in which protein is removed by denaturation with amyl alcohol and chloroform, much of the material of high sedimentation coefficients is lost during the first two extractions. It can be concluded that using this method of preparation produces a fractionation of the deoxyribonucleic acid rather than a degradation or denaturation, since (*a*) after the first two extractions further treatment does not affect the distribution, (*b*) deoxyribonucleic acid of higher sedimentation coefficients can be removed from the denatured protein residues and (*c*) transforming principle when prepared in this way retains its biological activity[6]. It has been reported that deoxyribonucleic acid prepared by this method has a lower molecular weight than that prepared using the detergent method[7]. Analysis of the base composition of deoxyribonucleic acid prepared by these two methods and of that from the denatured protein residues of the Sevag extractions showed no significant differences. This confirms the conclusion of Lucy[8] that there is no marked correlation between the size of the deoxyribonucleic acid particles and their base composition.

Previous work[9] has shown that when nucleoprotein is dispersed in water, in addition to a gel phase which is not dispersed on dilution, some soluble nucleoprotein is also present. The soluble component has been isolated by centrifugation and the distribution of the sedimentation coefficients of deoxyribonucleic acid present has been determined. As shown in Fig. 1*c*, the distribution covers a range of lower sedimentation coefficients than does the distribution for the deoxyribonucleic acid in the gel phase. If the nucleoprotein gel is allowed to stand at 4° C., it eventually becomes fluid. The loss of the high viscosity is accompanied by a progressive shift of the deoxyribonucleic acid distribution curve to lower values of sedimentation coefficients (Fig. 1*c*), suggesting that the deoxyribonucleic acid is being slowly degraded, probably by a small amount of deoxyribonuclease present in the preparation. Further experiments confirmed that nucleoprotein is susceptible to degradation by deoxyribonuclease, the addition of a small amount of the enzyme to the gel causing a much more rapid loss of viscosity than was observed for the gel alone and a correspondingly more rapid shift of the distribution to lower values of sedimentation coefficients.

These results suggest that some degradation of the deoxyribonucleic acid occurs before or during the isolation of the nucleoprotein from the thymus tissue, producing the soluble component of the nucleoprotein. It seems probable that degradation of the deoxyribonucleic acid at these early stages of the preparation may be the major cause of the variations observed between different preparations of the acid made by the detergent method, since no evidence of degradation or fractionation has been observed in this process of preparation of it from the nucleoprotein. Degradation of the deoxyribonucleic acid during the preparation of the nucleoprotein would also produce breaks in the single strands of the twin helix such as have been postulated to explain the decrease in molecular weight observed on heating deoxyribonucleic acid solutions[10].

Delayed Effect of Ipsilateral Intracarotid Infusion of Sodium Chloride on the Composition of the Parotid Saliva of Sodium-depleted Sheep

SHEEP with permanent unilateral parotid fistulæ may be maintained in good health indefinitely provided that sufficient sodium bicarbonate is added to the daily dietary intake to compensate for that lost in the hypertonic alkaline parotid saliva. It has been shown[1] that withdrawal of this supplementary sodium intake causes sodium depletion and, as depletion increases, the ratio of sodium to potassium in the parotid saliva falls progressively from a normal value of 180 : 10 to as low as 10 : 180. This response to sodium depletion is not significantly affected by changes in the potassium intake. Restoration of the dietary sodium bicarbonate supplement, in an amount sufficient to correct the sodium depletion, causes the composition of the parotid saliva to return to normal.

During the investigation of this aspect of parotid secretion, we have observed the effect of infusing a concentrated solution of sodium chloride into the ipsilateral carotid artery of sodium-depleted sheep. This caused, after a time delay of 100–150 min., a rapid increase in the ratio sodium/potassium of the parotid saliva. The rise occurred only if the infusion caused a significant change in the sodium balance of the animal.

The details of the experiments are as follows. In addition to a left parotid fistula, each sheep had a carotid loop in the neck on the same side[2]. Sodium depletion was produced by withholding or reducing the supplementary sodium bicarbonate. The degree of sodium depletion varied in the several experiments; but the ratio sodium/potassium of the parotid saliva was in all cases less than 1·0 on the day of the infusion. The procedure for sodium chloride infusion was essentially that described by Verney[3], with the modification that the experiment was performed during constant stimulation of the gland by the infusion of acetylcholine (1 : 50,000 in 5 per cent dextrose at the rate of 0·5 ml./min.) into the carotid loop. This acetylcholine infusion caused an abrupt and sustained increase in the rate of parotid salivary secretion as well as an increase in the ratio sodium/potassium to approximately unity. After a base-line period of 2–4 hr., during which the rate of parotid salivary secretion settled down to a relatively constant rate of 2–4 ml./min., and there was no further change in the ratio sodium/potassium, the sodium chloride solution was infused. This was made up to a concentration of 4 molar in distilled water, and infused into the carotid loop at a rate of 0·4 or 1·60 ml./min., using a motor-driven syringe. The saliva from the fistula was collected directly into a stainless steel tray, and the animal was conscious and unrestrained throughout the experiment.

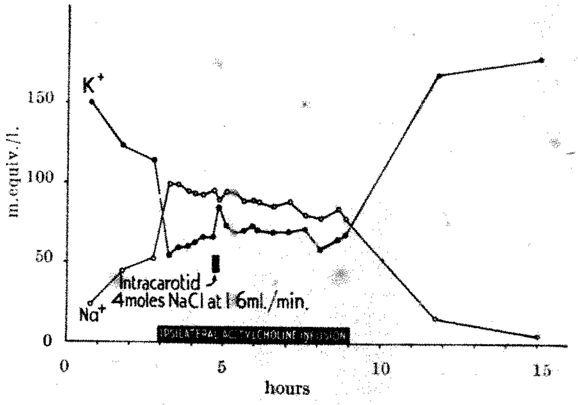

Fig. 2. Parotid fistula sheep No. 19, depleted of sodium. No change in the salivary sodium and potassium concentrations occurred after the rapid ipsilateral intracarotid infusion of 64 m.equiv. of sodium chloride (4·0 molar at 1·6 ml./min.)

In the first experiments, a total amount of 200–300 m.equiv. of sodium was infused over a period of 30–40 min. In most instances this caused an immediate small rise in the parotid salivary sodium concentration which persisted only until the end of the sodium chloride infusion. There was usually a fall in the rate of the salivary secretion during this period; but recovery occurred immediately after the infusion ceased. The ratio sodium/potassium in the saliva then returned approximately to the base-line level until 100–150 min. after the commencement of the infusion, when there was a rapid and progressive rise (Fig. 1). This was observed in three experiments in which the 4 *M* sodium chloride infusion was given at the rate of 1·60 ml./min., and in five other experiments in which approximately the same amount was infused at one-quarter that rate. The delay period was always at least 100–150 min. after the start of the sodium chloride infusion. As the total loss of sodium in the saliva during each experiment was, up to the time of the infusion, only about 60 m.equiv., the infusion caused a significant change in the sodium balance of the animal.

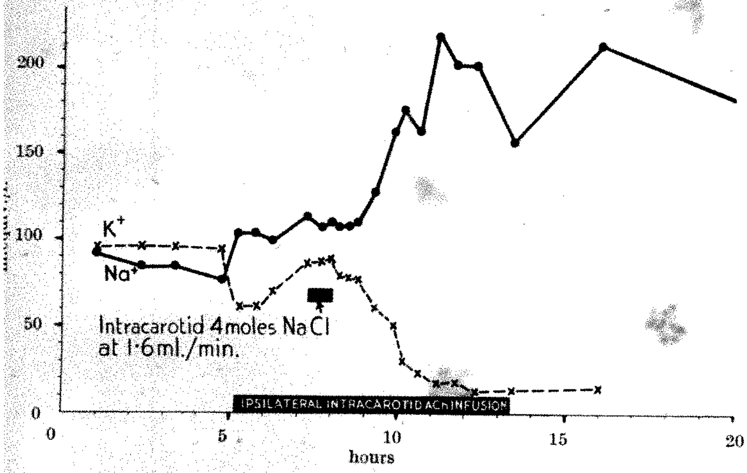

Fig. 1. Parotid fistula sheep No. 16, depleted of sodium. The delayed change in the saliva sodium and potassium concentrations after the rapid ipsilateral intracarotid infusion of 240 m.equiv. of sodium chloride (4·0 molar at 1·6 ml./min.)

Two experiments were made on sheep similarly prepared, in which the sodium chloride infusion was given at the rate of 1·60 ml./min., but for a period of only 10 min., so that the amount of sodium infused approximately equalled the amount lost in the parotid saliva during the experiment. No delayed change in the sodium/potassium ratio of the saliva occurred (Fig. 2).

Thus the delayed response to the sodium chloride infusion occurred only when the sodium balance of sodium-depleted sheep was significantly altered. Analysis of blood taken from the transverse facial artery of anæsthetized sheep has shown that the sodium concentration rises by 7–35 m.equiv./l. during the infusion of 4 *M* sodium chloride at these rates into the corresponding carotid artery. These considerations indicate that the return to a normal value of the ratio sodium/potassium in the parotid saliva was not due to a direct effect of the increased sodium ion concentration in the blood perfusing the gland. It seems likely that the site of action of the infused sodium ions was elsewhere in the body, and the time delay suggests that either a specific humoral agent was elaborated in response to the infusion, or the production of some agent necessary for the maintenance of a low salivary sodium/potassium ratio was inhibited. Investigation is proceeding to determine the site of the responsive region in the body, and the specific way in which changes in sodium balance may influence it. This experimental procedure, using a conscious undisturbed animal, should be of value in studying the biological regulation of sodium, since a change of sodium balance induces in the sensitive tissue a response of large magnitude on a short time-scale.

This work was aided by grants from the National Health and Medical Research Council and the Wool Industry Fund of the Commonwealth of Australia.

Effect of Cadmium Salts on Testicular Tissue

THE physiological action of cadmium salts has been studied extensively by many authors. Morphological disturbances have been described in various organs (liver, kidney, etc.). While studying the effect of cadmium salts on protein metabolism one of us (J. P.) observed that cadmium chloride administered subcutaneously to rats produces macroscopic lesions of the testes. This seems to have escaped the notice of previous authors and therefore this phenomenon was studied more closely.

Mature male rats weighing on an average 300 gm. were given 1 ml. 0·03 *M* aqueous solution of cadmium chloride or lactate subcutaneously between the shoulder-blades. Male rats injected with an equimolar solution of sublimate served as controls together with normal animals. Rats were killed 2, 4, 6, 8, 10, 12, 24 and 48 hr. after injection. Already 2–4 hr. after injection of cadmium chloride, capillary stasis and œdema of the interstitium could be observed microscopically. 8 hr. after injection extensive hæmorrhages developed. Occasionally leucocyte infiltration, which was rarely massive, occurred. Regressive changes of spermiogenic epithelium developed 4–6 hr. after the injection of cadmium chloride (desquamation of cells, pycnosis of nuclei, karyorrhexis and lysis of nuclei). 24–48 hr. after injection all testicular tissue was severely damaged.

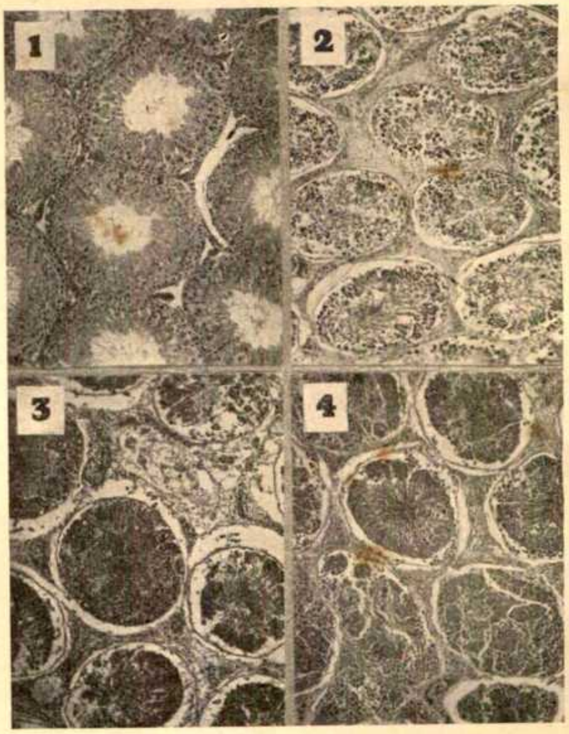

Fig. 1. Sublimate 48 hr. after application. Rat testis of normal appearance. Fig. 2. Cadmium chloride, 48 hr. after application. Collapse of tubules, œdema of intertubular spaces, desquamations and pronounced degenerative changes of the spermiogenic epithelium. Fig. 3. Cadmium lactate, 48 hr. after application. Histological picture as in Fig. 2. Fig. 4. Cadmium chloride, 12 days after application. Total necrosis of testicular tissue. (Bouin, hæmatoxylin-eosin; × c. 60)

On the following days all nuclear remain disappeared and complete testicular necrosis set in Cadmium chloride and lactate have the same effect whereas sublimate does not produce any obviou histological changes in the testes. Morphologica lesions in the ovaries of female rats after cadmiun chloride administration were not observed: bu functional changes cannot be excluded. The change described were found in the testes of all animal tested (80 males), whereas changes in other organ were only slight, except in the liver, where the varied in extent.

Work on this problem is being continued.

Oct. 25.

IT has been shown (preceding communication) tha the subcutaneous application of small amounts o cadmium salts results in a rapid destruction of al tissues of the testicle.

Recently, Elcoate, Fischer, Mawson and Milla showed that prolonged nutritional deficiency of zin causes testicular injury[1]. It may be asked whethe e effect of cadmium on testicular tissue is not mparable to the effect of a lack of zinc, the former ing rapid and sudden. In our experiments it was ssible to protect testicular tissue of adult rats mpletely from the destructive effect of cadmium ·04 m.mole cadmium chloride/kgm. body-weight bcutaneously) by the simultaneous administration 80, 100 and 200 times the amount of zinc, injected the form of acetate subcutaneously in divided ses before, simultaneously with, and after, applica-on of cadmium.

Of all soft tissues, spermatozoa (and the prostate) ntain the largest amount of zinc. Turnover of nc is greatest in the testes[2]. Cadmium and zinc re physico-chemically very close to each other. It therefore attractive to speculate that cadmium splaces zinc from those molecular structures into hich zinc is probably incorporated during the aturation of spermatozoa. In view of the fact at it has been possible to suppress the destructive fect of cadmium on the testis by using many times e dose of zinc, a mechanism of competitive inibition between these two metals may be suggested.

ction of an Autolytic Enzyme of *Bacillus subtilis* on the Cell Wall

Many biologically produced substances are known o lyse living micro-organisms. Among them, ysozyme has been studied most extensively for the echanism of its action, and it has been shown that his action is the dissolution of cell wall, probably he hydrolysis of mucopolysaccharide contained in t[1]. Studies on the action of autolytic enzymes, on he other hand, are few, and their site of action has ot hitherto been known. Recently, one of us bserved very rapid autolysis of amylase-producing trains of *Bacillus subtilis*[2] and isolated an autolytic ubstance(s) from the lysate[3]. Studies on this autoytic substance(s) have shown that it lyses the cell vall.

An autolytic enzyme preparation was obtained rom the lysate of *B. subtilis H* by precipitation with mmonium sulphate. Cell-wall preparation was btained from the same bacterium. Washed cells vere disrupted by boiling at 100° C. for 10 min. and, urther, by exposure to supersonic vibration. Disupted cells were digested successively with crystalline rypsin, crystalline *B. subtilis* protease and crystalline hymotrypsin. The residue seemed to consist mainly f cell wall when examined in the electron microscope. s shown in Fig. 1, this cell-wall preparation was issolved by the autolytic enzyme solution (crystalline ysozyme also dissolved it, but crystalline ribonuclease ad no effect). Electron microscope examination also onfirmed this result.

Further investigation of the mechanism of lytic ction was undertaken against living bacteria. ecently, Weibull[4] succeeded in dissolving the cell wall only, by the controlled treatment with lysozyme in sucrose, and obtained protoplast. The protoplast of our strain, *B. subtilis H*, was also formed by treatment with lysozyme in the presence of 10–15 per cent sucrose or polyethylene glycol. Therefore, the effect of high concentrations of these substances on the lytic action of the autolytic enzyme solution was examined. Complete protection was observed during the first 1–2 hr., but thereafter lysis occurred and action seemed to take place in two steps: the dissolution of the cell wall, and disruption and lysis of the resulting protoplast. When the enzyme solution was heated at 100° C. for 10 min., the autolytic activity was completely abolished. This boiled solution was added to the cell suspension in sucrose (15 per cent) together with the lysozyme solution. Complete lysis occurred, whereas only protoplast formation was observed without boiled enzyme solution. Therefore it was concluded that this enzyme solution contains a heat-stable substance(s) which causes the disruption of the protoplast in addition to the heat-labile enzyme which dissolves the cell wall.

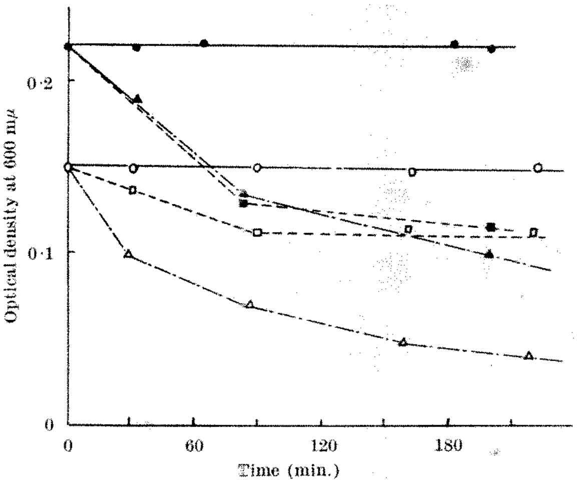

Fig. 1. Action of the autolytic enzyme solution and lysozyme on the cell-wall preparation. The cell-wall preparation was suspended in *M*/30 phosphate buffer, mixed with the autolytic enzyme solution or lysozyme solution as indicated. Total volume, 6 ml., *p*H 7·2. Rate of dissolution at 30° C. was followed by measuring the changes of optical density at 600 mμ

Set 1: ●—●, control; ■—■, plus 1 ml. autolytic enzyme solution; ▲·—·▲, plus 3 ml. autolytic enzyme solution. Set 2: ○—○, control; □—□, plus lysozyme 0·67 γ/ml.; △·—·△, plus lysozyme 6·7 γ/ml.

In view of these and other results, it seems reasonable to conclude that the primary site of action of this autolytic enzyme solution is the cell wall, probably the polysaccharide contained in it (polysaccharide was isolated from the cell and its depolymerization by this enzyme solution was demonstrated (unpublished results)). A more detailed account of this work will be published elsewhere.

Effect of Carbon Dioxide on the Manganese Absorption of Red Beet Tissue

In an earlier publication[1] the discovery was reported of a substance extractable by water from red beetroot and capable of inhibiting the active accumulation of manganese by slices of storage tissue. It was suspected at the time that the substance might be produced by the dark fixation of respiratory carbon dioxide which, as Burton[2] showed for potatoes, may reach concentrations of about 7 per cent in bulky storage organs. I have now shown that the presence of carbon dioxide in solutions from which beetroot tissue slices are absorbing manganese reduces the rate of absorption. The reduction in rate is proportional to the concentration of carbon dioxide up to about 40 per cent, at which the rate appears to be minimal.

When slices of beetroot tissue are freed from natural inhibitor by prolonged washing in running water, inhibition of salt absorption capacity can again be produced by exposing the tissues to carbon dioxide in gaseous form before placing in the manganese solutions. The degree and duration of this condition depend on the concentration and duration of exposure to carbon dioxide. These facts support the hypothesis that a naturally occurring inhibitor of salt absorption may be a carbon dioxide fixation product. Further support is provided by the fact that a greater degree of inhibition results when beetroots are stored at temperatures of about 25° C. instead of the more usual 10° C., and when they are stored in closed containers so that respiratory carbon dioxide accumulates.

The exposure of inhibitor-free beetroot tissue to carbon dioxide concentrations of about 3 per cent (or short exposures to concentrations up to 10 per cent) when oxygen was the complementary gas produced a subsequent stimulation of manganese absorption on placing in solutions free from carbon dioxide, although higher concentrations or longer exposures produced the usual inhibition. This suggests the possibility of the formation of another fixation product or the oxidation of the inhibitor to form a metabolic stimulant. It is hoped that full results will be reported elsewhere.

Dale and Sutcliffe[3] question the significance of a water-extractable inhibiting substance in connexion with the dormancy of stored beetroot or the development of a capacity for salt absorption in slices of cut tissue, and they claim that the observations of Skelding and Rees were due to the presence of relatively indiffusible anions such as malate and citrate in the extracts. This may well have been the case, although Dale and Sutcliffe quote no figures for the organic acid content of their tissue extracts to support it. The results reported above are, however, consistent with the formation in beetroot tissue of an inhibiting substance, and the formation of acids by carbon dioxide fixation in plant tissues is well known. It could be the case that the presence of organic acids in the cytoplasm in certain concentrations is inhibitory; but if so the explanation would more probably lie in a specific action of the acid on absorption centres rather than in the presence of an ion of low mobility in the external solution. The effect of externally applied malate might also be on absorption centres. If the hypothesis put forward here as to the reason for the undoubted low level of salt absorption capacity in newly cut storage tissue is correct, an inhibiting substance ma well be of significance in the life of tuber-formin plants.

A Selective Medium for the Isolation of Basidiomycetes

In the course of a programme of work involvin the isolation of wood-rotting fungi from infecte Scandinavian wood-pulp, considerable trouble wa experienced with rapidly spreading mould contaminants, particularly *Trichoderma viride*[1]. In man cases, attempts to isolate Basidiomycetes from stain known to be caused by these fungi failed, due nc only to the growth of *Trichoderma* which in a shor time covered the surface of the malt agar mediun but doubtless also to secretion of the antibiotic viridin and gliotoxin by this mould, which are activ against many fungi[2]. Experiments have shown tha *Trichoderma* isolated from wood-pulp is able to retard and in some cases prevent, the growth in artificia culture of various Basidiomycetes.

This difficulty has now largely been overcome i these laboratories by the development of a selectiv medium containing 0·006 per cent *o*-phenyl phenol which has given good results both when used for th isolation of wood-rotting fungi from wood-pulp anc also, in conjunction with an air-sampling apparatus from the air in a pulp mill. The latter work wa done in an attempt to demonstrate the presence o Basidiomycete diaspores in the aerial microflora of Norwegian pulp mill, and was very successful. Usin the selective medium, ***Fomes annosus*** was isolatec from several locations together with four other (a present unidentified) Basidiomycetes. None wa obtained by exposing plates of normal malt agar.

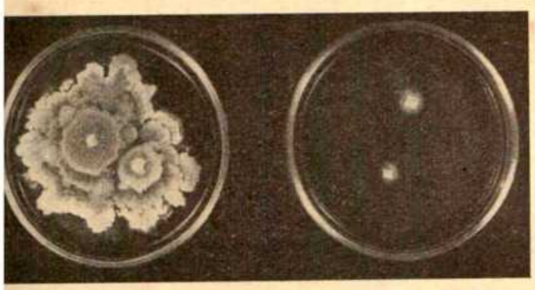
The selective medium has the following composition:

'Oxoid' desiccated malt extract	3 gm.
'Oxoid' mycological peptone	0·5 gm.
Agar-agar	2·5 gm.
o-Phenyl phenol	0·006 gm.
Distilled water	100 ml.

The medium is autoclaved at 10 lb./in.^{2} for 10 min The required amount of *o*-phenyl phenol is addec from a stock solution prepared by dissolving 1 gm in 50 ml. industrial alcohol. This solution is dilutec to 100 ml. with distilled water and is quite stable.

Extensive tests have been carried out with thi medium. We have found that several Basidiomycete isolated from wood-pulp will grow, albeit slowly, ir media containing up to 0·01 per cent w/v of *o*-pheny phenol. The growth of bacteria can at the same time be prevented by the normal method of lowering the *p*H of the medium to about 3·5 with sterile lacti acid, without affecting the selective action of the *o*-phenyl phenol towards Basidiomycetes.

At a concentration of 0·006 per cent *o*-pheny phenol, certain moulds (for example, *Cladosporium* sp., *Alternaria* sp., *Penicillium* spp.) will produce restricted colonies after about a fortnight on the medium. Also, from one pulp sample, a strain o



(1) (2)

ig. 1. Contiguous fragments of infected wood-pulp on normal id selective malt agar. (1) Only *Trichoderma* growing. (2) *Trichoderma* suppressed, Basidiomycete isolated

ichoderma was isolated which was highly resistant *o*-phenyl phenol. Nevertheless, the medium has ved to be sufficiently valuable to be used in the itine examination of infected wood-pulp.

n general, the micro-fungi appear to be much re sensitive to this chemical than the Basidio-cetes normally encountered in this work. (The y wood-rotting fungus so far observed which led to grow on the medium was *Merulius lacrymans*.) e concentration of *o*-phenyl phenol can apparently increased somewhat if desired, and it is thought it the medium could be used with advantage in isolation of Basidiomycete fungi from soil, terials frequently heavily infected with superficial ulds such as wood-pulp and bark, building boards, shwater, pulp mill whitewaters and the air.

Fig. 1 illustrates the result of placing infected gments of wood-pulp, taken from adjacent positions, normal and selective malt agar plates. Complete pression of *Trichoderma*, which was sporing freely the pulp, has been obtained with the selective dium, and the Basidiomycete responsible for the -stain under examination has been successfully lated.

Incorporation of Carbon-14 into the Complex Polysaccharides of Plants

The carbon-14 tracer technique would appear to er a unique opportunity for investigations of the synthesis and subsequent metabolism of pectins d hemicelluloses, provided that there is a measur-le synthesis and turnover of these polysaccharides plant tissues. After allowing four mature fruiting urs, each with four to six leaves and two fruits, tached from plum trees (variety Victoria), to otosynthesize[1] in the presence of carbon-14 dioxide om 43·5 µc. barium carbonate-^{14}C), the leaf poly-charides and the water-soluble polysaccharides of e fruit mesocarp were isolated. Labelling of all the onosaccharide constituents was observed by hydro-sing the polysaccharides (*N* sulphuric acid ; 100° ; hr.), separating the products on paper chromato-ams and examining with a Geiger counter those eas containing the separated sugars. The specific tivities of the latter were determined, after elution from the paper chromatograms, as infinitely thin films on planchets (see Table 1). The incorporation of carbon-14 into the fruit mesocarp polysaccharides may be due to photosynthesis by the fruit or by translocation from the leaves.

Table 1

Monosaccharide	Specific activity (counts/min./mgm.)	
	Leaf polysaccharides	Mesocarp polysaccharides
Galacturonic acid	882	20
Galactose	1,342	31
Glucose	3,110	—
Arabinose	334	11
Xylose	180	—
Rhamnose	184	—

The highly active glucose undoubtedly arose from leaf starch. Clearly, the complex polysaccharides are biosynthesized in the leaf and mature plum fruit tissues, thus suggesting the existence of a dynamic equilibrium between these polysaccharides and their monosaccharide constituents in a manner analogous to the animal proteins. Jermyn and Isherwood[2] have made an analytical study of the cell-wall polysaccharides of pear fruit at various stages of ripening, with the conclusion that certain of the polysaccharides were being synthesized in over-ripe fruit. The synthesis of complex polysaccharides in mature fruit tissues is contrary to the classical view.

This work forms part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Mitochondrial *Nebenkern* of the Water-boatman

During the past few years, in the course of an investigation of the chemical composition of the acroblasts ('Golgi apparatus') in the spermatogenesis of the water-boatman (*Notonecta glauca*), I have been impressed by the structure of the mitochondrial *Nebenkern* of this animal. The male germ-cells of *Notonecta* are very large, the spermatozoon being more than a centimetre long, and the *Nebenkern* is probably the largest single body of mitochondrial origin that occurs in any organism. Its development and subsequent history were worked out long ago by Pantel and de Sinéty[1], Poisson[2] and Voïnov[3]. It is formed by the fusion of the mitochondria present in the young spermatid.

The purpose of this communication is to direct attention to the curious resemblance between the internal structure of this *Nebenkern* as seen by the light-microscope, and that of the ordinary mitochondrion as revealed in recent years by the electron microscope. Fig. 1 represents a section of the *Nebenkern* of the young spermatid of *Notonecta*. It is seen to be traversed by flat partitions, which show at

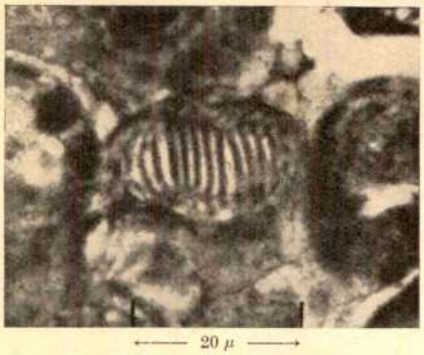

Fig. 1. The ovoid *Nebenkern* in the young spermatid of *Notonecta glauca*. Twelve partitions can be counted. (Fixed in Mann's fluid; paraffin section stained in Hirschler's hæmatoxylin)

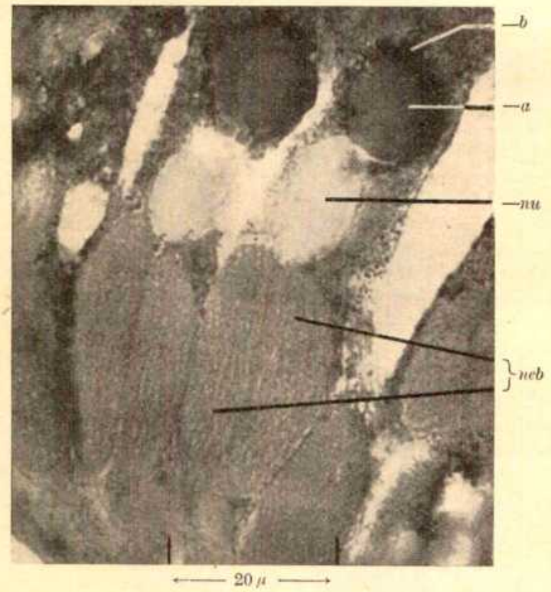

Fig. 2. Two elongating spermatids of *Notonecta glauca*. *a*, Acrosome in its vesicle; *b*, group of acroblasts; *neb*, elongating *Nebenkern*, now divided in two; *nu*, nucleus. (Weigl's method; unstained 4-μ section)

least some superficial resemblance to the cristæ mitochondriales of the electron microscopists. The scale of the objects is, however, extremely different. The mean distance from the middle of one partition to the middle of the next, in the *Nebenkern*, is about 1,600 mμ; in the ordinary mitochondrion the corresponding distance is commonly about 30–60 mμ (see, for example, Sjöstrand and Rhodin[4]). Sections passing at various angles through the *Nebenkern* show that the partitions are not arranged in the same way as the cristæ; nevertheless, it is interesting that a laminated structure exists in both objects.

In the later spermatid the *Nebenkern* divides in two and each half elongates (Fig. 2). The laminated structure is now much less evident.

Leafhopper Transmission of a Clover Vir
causing Green Petal Disease in Strawber

THE symptoms of green petal disease[1] of stra
berries in Britain resemble those caused by the as
yellows virus[2] in strawberries in California. In seve
localities where the disease occurs in Kent, sympto
of the aster yellows type were also found in red a
white clover (*Trifolium pratense* L. and *T. repens* I
plantain (*Plantago major* L.) and mayweed (*Anther*
cotula L.).

In the search for vectors of green petal vir
collections of mixed species of leafhoppers from he
age in and near strawberry fields were caged
diseased plantain and clover plants for appr
imately three weeks. The insects that surviv
represented only two species, *Euscelis lineola*
Brullé and *Macrosteles viridigriseus* (Edwards) (
termined by Dr. D. A. Young, U.S. National Museu
Washington, D.C.); to test them as vectors th
were transferred to successive plants of red clov
white clover, celery, mayweed, plantain, *Fraga*
vesca L. and *Duchesnea indica* Focke. In the fi
tests large numbers of insects were fed on each t
plant; later, single insects were transferred to you
seedlings of crimson clover (*T. incarnatum* L.).

Mixed colonies of *E. lineolatus* and *M. viridigris*
infected nine out of twelve clover, four of six ma
weed, and one of three celery test plants. In separ
tests with the two species of leafhoppers, *E. lineola*
colonies infected nine of fourteen clover plants, a
a further nine transmissions occurred with sin
insects. As plantain proved to be a better host th
clover for *M. viridigriseus*, most of the insects of t
species were fed on plantain test plants; these ha
developed such mild symptoms in the glasshou
that diagnosis of virus infection is uncertain. O
one definite transmission, to mayweed, has occurr
with *M. viridigriseus*.

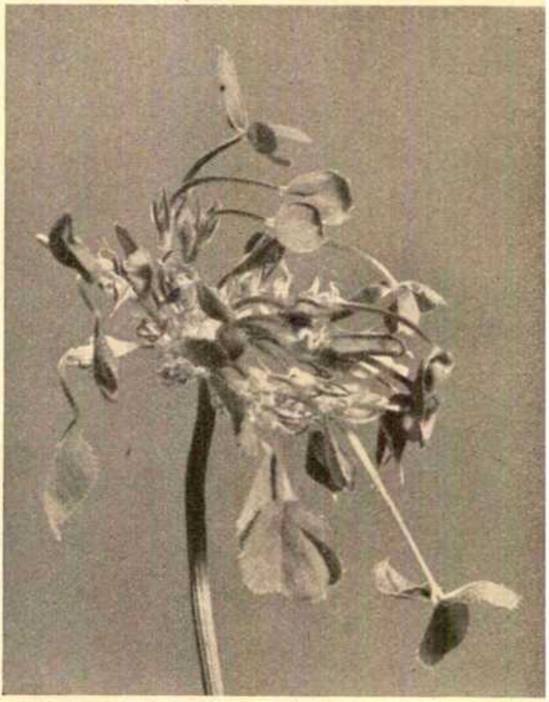

Fig. 1. Virus-induced phyllody in white clover flowers on plan
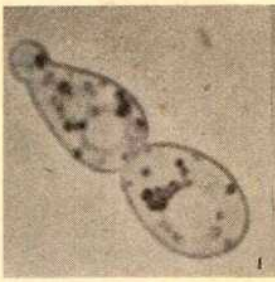
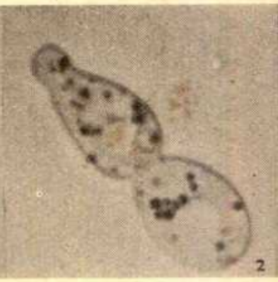
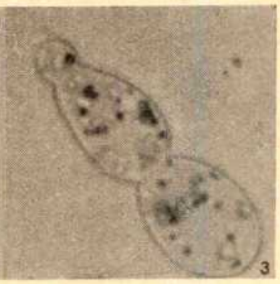
infected by *Euscelis lineolatus*



1



2



3

3oth species failed to infect
strawberry and *D. indica*
plants, and the relation-
p between the leafhopper-
nsmitted virus and green
al disease was determined
transmission effected by
lder. *Cuscuta subinclusa*
and H. transferred the
us from clover to straw-
ry and *D. indica* plants,
ich developed the charac-
istic leaf and flower symp-
ns of green petal disease. Strawberry plants of
variety Lassen produced identical flower symp-
ns whether infected by dodder from clover or by
fting to green petal-infected strawberry.

The general similarity in symptoms and host-range,
d in the resistance shown by strawberry to experi-
ntal infection by leafhoppers, suggests that green
al disease may be caused by a strain of the aster
lows virus. There are, however, differences in
nptoms on all hosts, implying a distinction be-
een the green petal and both the eastern and the
stern aster yellows viruses.

The frequent occurrence of the disease in isolated
awberry fields suggests that the green petal virus
y be widespread in clover. The prominent phyllody
the clover flowers (Fig. 1) should have directed
ention to this disease, but it may have been
ributed to damage by *Dasyneura* midges or
ytoptid mites. Infected red clover plants are
nted, with yellow leaf margins and veins, and a
oliferation of axillary buds. White clover, although
veloping clear symptoms, seems less sensitive than
l, many plants of which have been killed within
few months of infection.

This is the first virus shown to be transmitted by
fhoppers in Britain.

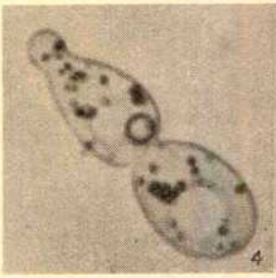
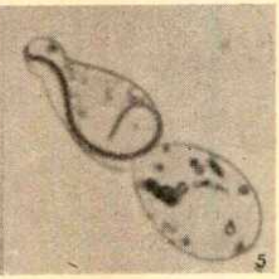
Cytoplasmic Structures in Yeasts

YOTSUYANAGI[1] has reported long, curved,
lindrical, occasionally branched, thread-like mito-
ondria in yeast cells by staining with tetrazolium.
though mitochondria are often clearly visible in
ing yeast cells, no other observer has ever reported
ng cylindrical cytoplasmic structures in *Saccharo-
yces*; we believe these thread-like structures are
ystals of dye rather than mitochondria.

Figs. 1, 2 and 3 show a yeast cell at three optical
els after 15 min. staining with 2,3,5 triphenyl
razolium. The mitochondria in Fig. 1, in central
us, are darkly stained structures with clear centres,
owing that the dye is deposited on the outside of
e mitochondrion. Fig. 2 shows the same structures
low focus as dark spots; a deposit of tetrazolium
forming. Fig. 3 shows the same cell in high focus;
e stained mitochondria appear as light areas due
the refraction of light by the granules. One hour
er (Fig. 4) the deposit is much darker. After



4



5

another hour (Fig. 5) a crystal of tetrazolium extends across the cell. It is probably structures like this which Yotsuyanagi[1] and Ephrussi and Slonimski[2] have mistaken for mitochondria. In other cells crystals of dye appear as plates or short broad rods.

Ephrussi and Slonimski[2] and Yotsuyanagi[1] have proposed that three kinds of cytoplasmic granules are present in yeasts: (1) long cylindrical threads, (2) refractile granules which they do not think are mitochondria and (3) small 'true' mitochondria.

We have shown that deposits of formazan, especially the thread-like structures, are dye crystals, not resembling any normal structure present in the yeast cell.

This work was supported by a grant from the American Cancer Society administered by the Committee on Growth, National Research Council.

---

[1] Yotsuyanagi, J., *Nature*, 176, 1208 (1955).

[2] Ephrussi, B., and Slonimski, P. P., *Nature*, 176, 1207 (1955).

THE above comment on our papers starts with the assertion that "Yotsuyanagi has reported long, curved, cylindrical, occasionally branched, thread-like mitochondria in yeast cells by staining with tetrazolium". This is incorrect; the thread-like mitochondria referred to were stained with janus green and with Altmann's fuchsin. The observation of Williams, Lindegren and Yuasa that "deposits of formazan, especially the threadlike structures, are dye crystals not resembling any normal structure present in the yeast cell" is therefore irrelevant.

On the other hand, Williams *et al.* state: "Ephrussi and Slonimski and Yotsuyanagi have proposed that three kinds of cytoplasmic granules are present in yeasts: (1) long cylindrical threads, (2) refractile granules which they do not think are mitochondria and (3) small 'true' mitochondria". Our papers show, however, that the small granular and the long thread-like mitochondria represent, in our opinion, two physiological states of the chondriome.

Leptospirosis in Piggery Workers

It is generally believed that human cases of the type of leptospirosis known as canicola fever arise through man's contact with infected dogs, the dog being the only natural host and carrier of the infecting organism, *Leptospira canicola*. The infection in the dog may lead to a clinically recognizable disease with acute renal symptoms leading to the death of the animal; but a milder condition may occur and may escape detection. All degrees of infection give rise to the carrier state, which may persist for months or even years, during which time the leptospiras are expelled in the urine, which thereby constitutes a potential source of infection to other dogs and man.

Although the probable source of many human cases of canicola fever has been traced directly or indirectly to dogs, there have been instances where no connexion between patient and dog could be found. Four examples of such cases gave rise to an investigation into a possible alternative source of infection, the results of which present some interesting features. The patients concerned in these four cases, which arose during the years 1950–55, were all persons employed in piggeries situated within the City of Edinburgh. It seemed unlikely that the farm dogs were responsible for the infection, since they appeared healthy, and sera obtained from them failed to agglutinate *Leptospira canicola* to more than a low titre. In one of the piggeries where a single case had occurred, it was possible to obtain specimens of blood from all of the other human contacts living and working there, namely, three men and two women. Agglutination tests show that in four of these bloods, antibodies to *Leptospira canicola* were present in high titre—1/1,000 to 1/10,000. The one person whose blood failed to show any response to the agglutination test was the young wife, who was the only member of the household having no contact with the pigs.

Blood samples were taken from some of the pigs selected at random at the time of slaughter. Of seventy-six such specimens forty-six were found to have antibodies to *Leptospira canicola* giving titres of at least 1/100 (fifteen were 1/1,000 to 1/10,000). *Leptospira icterhaemorrhagiae* was agglutinated to a lesser degree. No antibodies to *Leptospira pomona*, *Leptospira hyos* or *Leptospira biflexa* were found in any of the samples tested.

These results indicate that pigs may become infected with a species of Leptospira closely related to, if not identical with, *Leptospira canicola*. If the responsible organism is indeed *Leptospira canicola*, the infection may have been introduced into the piggery in the first place by an infected dog, and once established there the infection has continued to spread directly from pig to pig.

To investigate the infectivity-rate among pig workers, blood specimens were obtained from forty-seven workers employed in twelve different pigge
(these figures include those already mentione
Agglutination tests showed that nineteen (that
40 per cent) contained a high antibody content
Leptospira canicola—1/100 to 1/10,000. *Leptos*
icterhaemorrhagiae was agglutinated to a les
degree.

An explanation of this apparently high infectivi
rate may be that the workers' hands are freque
contaminated with infected urine. The conditi
of their work seem to predispose them to cuts a
abrasions which do not heal readily. These inju
and the fact that the hands are often wet fr
frequent submersion in water will allow the lep
spira to penetrate into the skin readily.

Further inquiry regarding the health of th
workers whose bloods were positive to *Leptosp*
canicola revealed that during the past five years, f
of them had suffered from an illness diagnosed
canicola fever and, of the remaining fourteen, f
had a history suggestive of the disease. No mark
symptoms of disease in the pig have been observ
but leptospira have been seen in the urine.

Further work is in progress, and it is hoped t
the results of the complete investigation will
published in detail elsewhere at an early date.

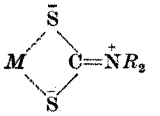
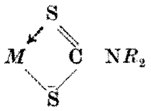
Electronic Structures of Dithiocarbamat and Xanthates

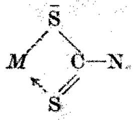
It has long been realized that the canonical fo
(I*a*) may contribute significantly to the structure
the dithiocarbamate residue in its complex co
pounds, $M(S_2CNR_2)_n$, where M is a metal atom a
n its valency, but no physical or chemical eviden
for this has yet been advanced.



(I*a*)



(I*b*)



(I*c*)

Recently, van der Kerk and his co-workers[1,2] ha
suggested that (I*a*) contributes strongly to the stru
ture of methyl derivatives (R = Me) but that i
importance decreases rapidly on ascending t
homologous series. They consider the dipolar for
(I*a*) to be responsible for the antifungal and plan
growth promoting properties of certain derivativ
of NN-dimethyldithiocarbamic acid. Since the bi
logical activities of the NN-dialkyldithiocarbama
derivatives fall rapidly on ascending the homologo
series, they conclude that the contribution of t
form (I*a*) to the structures also falls rapidly. A
the time of their later publication[2], we had examine
the infra-red spectra of a number of complex N
dimethyl- and NN-diethyldithiocarbamates and inte
preted the so-called 'thioureide ion' band[3] in ter
of the canonical form (I*a*). This band had previous
been identified in many thioureides but not sati
factorily interpreted[3,4]. Van der Kerk's publicatio

ompted us, however, to extend our investigation
higher homologues and to organic derivatives. We
w report briefly our conclusions.

In general, we find that the forms (I*a*), (I*b*) and
) contribute about equally to the structures of all
N-dialkyldithiocarbamic acid derivatives, and that
ere is no significant decrease in the importance of
e form (I*a*) on ascending the homologous series.
e canonical form of type (I*a*) probably contributes
out equally strongly to the structures of the
monoalkyldithiocarbamates, but only in a com-
ratively minor way to the structures of the
nthates.

Our evidence for this is based on an infra-red
ectral investigation of some thirty derivatives of
N-dialkyldithiocarbamic acid, and on the dipole
oments of some unsymmetrical derivatives. The
pes of compounds examined included salts, for
ample, $Na(Me_2NCS_2)$, complex salts, for example,
$(Et_2NCS_2)_3$, an ester, Me_2NCS_2Me, and a sulphide
$e_2NCS_2)_2$. All have a strong absorption band,
e 'thioureide ion' band, in the 1,542–1,480 cm.$^{-1}$
gion of the spectrum, usually around 1,500 cm.$^{-1}$.
is too high in frequency to be due to a vibration,
e form of which is largely determined by stretching
a single C—N bond, or of a double C=S bond[3];
frequency is also too high for it to be assigned to
deformation mode of the methyl groups[4], for this
uld not occur at frequencies greater than 1,480
.$^{-1}$. The only possible assignment appears to be
a polar C—N double bond, and this implies that
e canonical form (I*a*) makes an important contribu-
n to the ground-states of all NN-dialkyldithio-
rbamates.

If this conclusion is correct, unsymmetrical deriva-
es of dialkyldithiocarbamic acids should have
rge electric dipole moments, because the form I(*a*)
highly dipolar. Most complex dithiocarbamates
esumably have centro-symmetrical structures, but
ose of type $As(R_2NCS_2)_3$ must be unsymmetrical,
cause arsenic(III) has a lone pair of electrons;
e esters R_2NCS_2R must also be unsymmetrical. In
ct, the dipole moments of these two types of
rivatives are high, of the order 4·5–5·0 and 3·0
bye units respectively[5]. To account for these
oments in the esters the C—N bond must have a
nd order of 1·25–1·35, that is, the forms (I*a*), (I*b*)
d (I*c*) contribute about equally to the structure.
The unsymmetrical N-alkyldithiocarbamates have
nilar dipole moments to the corresponding NN-
alkyldithiocarbamates[5], and the spectra of the
w monoalkyl derivatives which we have examined
have an absorption band in the 1,500 cm.$^{-1}$ region.
parently their electronic structures are similar to
ose of the NN-dialkyldithiocarbamates.

The unsymmetrical xanthates have comparatively
w moments of less than 2 Debye units in the cases
$As(ROCS_2)_3$, and of the esters, $ROCS_2R$ [5]. These
e of the same order as those of the symmetrical
mplex dithiocarbamates[5], xanthates[5] and acetyl-
etonates[6]. We have therefore examined the
ectrum of $Ni(EtOCS_2)_2$, and find that it is trans-
rent in the double-bond region[7]. There is a broad
nd at 1,265 cm.$^{-1}$ which is in the right place for
unsaturated ether[8]. We conclude, therefore, that
e canonical form $-\overset{-}{S}_2C{=}\overset{+}{O}R$ contributes com-
ratively little to the structure of the xanthates.

In view of the suggestion of van der Kerk and his
-workers, we examined a homologous series of
pper NN-dialkyldithiocarbamates. Our observations are recorded in Table 1. It is evident that the C=N frequency is almost independent of the size of the alkyl groups, and such change as we observe in the solid state is mainly due to crystal forces. It appears that the observations of van der Kerk and his co-workers cannot be explained as due to the much greater contribution of form (I*a*) to the structures of the lower homologues. Perhaps increasing lipoid- or decreasing water-solubility may provide an explanation of the decreasing biological activity as the series is ascended.

Table 1. C=N STRETCHING FREQUENCIES (cm.$^{-1}$) OF CUPRIC NN-DIALKYLDITHIOCARBAMATES, $Cu(R_2NCS_2)_2$, IN CHLOROFORM SOLUTION (± 2 cm.$^{-1}$) AND IN THE CRYSTALLINE STATE

R	Me	Et	Pr^n	Bu^n	Pr^i
Solution	insol.	1,505	1,502	1,505	1,490
Solid	1,524	1,508	1,501	1,497	1,493

The greater contribution of the canonical form of type (I*a*) to the structure of the dithiocarbamates than to that of the xanthates undoubtedly arises from the greater mesomeric electron-releasing tendency of the —N*R*$_2$ group as compared with the —O*R* group. In the dithiocarbamates, this greater electron drift into the sulphur atoms will increase their electron donor capacity, and decrease the electron affinity of their *d*-orbitals as compared with the sulphur atoms in the corresponding xanthates. Thus the dithiocarbamate ion should form stronger complexes, with less tendency to dative π-bond formation from the metal to the sulphur atoms, than the xanthate ion. This may well provide some explanation of the rather striking differences between the chemistry of the complex dithiocarbamates and complex xanthates[9].

Full details of this work will be published elsewhere.

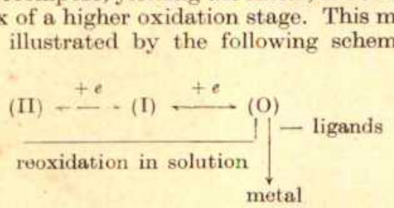
Formation and Reduction of Zero-Valent Metal Complexes studied Polarographically

IN the course of the reduction of inorganic compounds the electron is always accepted by the lowest unoccupied (or singly occupied) orbital in the depolarizing particle, regardless of whether this orbital is localized in the central metal atom (or some ligand-atom) or whether it is an unlocalized molecular orbital. After the acceptance of the electron, a rearrangement of electrons and ligands takes place leading to the most stable configuration of the particle with one more electron formed in the reduction. The rate and mechanism of the electrode process depend on the rate and mechanism of this rearrangement.

The electronic structure of the particle determines whether the acceptance of the first electron will cause a great rearrangement, leading in some cases to the decomposition of the particle, or whether the second electron can be accepted immediately.

The reduction of transition metal ions in oxidation stage + 2 is a special case of the latter mechanism[1]. The inner *d*-orbitals of these ions are not fully occupied by electrons localized in the metal atom, and the electron can be accepted by these orbitals during the reduction. In complexes with most ligands, the ion in oxidation stage + 1 thus formed is sufficiently stable to accept the second electron while forming a complex containing the metal in the zero oxidation stage. The rearrangement or decomposition of the particle does not take place until the second electron has been accepted. The zero-valent complex may either decompose, yielding the metal, or reoxidize to a complex of a higher oxidation stage. This mechanism can be illustrated by the following scheme:



The mechanism of the chemical reactions of the zero-valent complexes may be complicated (for example, due to dismutation).

The formation of metal complexes in low oxidation stages has been demonstrated during the reduction of nickel (II)-complexes. The height of the reduction wave of the ion $Ni(CN)_4^{2-}$ corresponds to the acceptance of two electrons per nickel atom. During the reduction of $Ni(CN)_4^{2-}$, a red colour and the evolution of hydrogen at the electrode surface are observed. This effect can be ascribed only to the oxidation of the ion $Ni(CN)_4^{4-}$, formed as a primary product of the electrode reaction, to the ion $Ni_2(CN)_6^{4-}$, which is not reducible. Other experiments support this conclusion. The oscillopolarographic curves for d*V*/d*t* versus *V* (Fig. 1) point to one reversible redox process, corresponding to the reversible reduction of $Ni(CN)_4^{2-}$ and oxidation of $Ni(CN)_4^{4-}$; and also to one irreversible anodic process, corresponding to the oxidation of the ion $Ni_2(CN)_6^{4-}$, formed by the reacti of $Ni(CN)_4^{4-}$ with water. Polarography with t Kalousek commutator[2] points to the same processe The form of the reduction wave of the ion $Ni(CN)_4$ is in agreement with the proposed mechanism a may be deduced theoretically. The height of t cathodic wave of $Ni(CN)_4^{2-}$ in solutions with high concentration of cyanide ions or in acid solutions greater than would correspond to a two-electr process. This increase of current can be ascribed the regeneration of the ion $Ni(CN)_4^{2-}$ by oxidati of $Ni(CN)_4^{4-}$ ion with water.

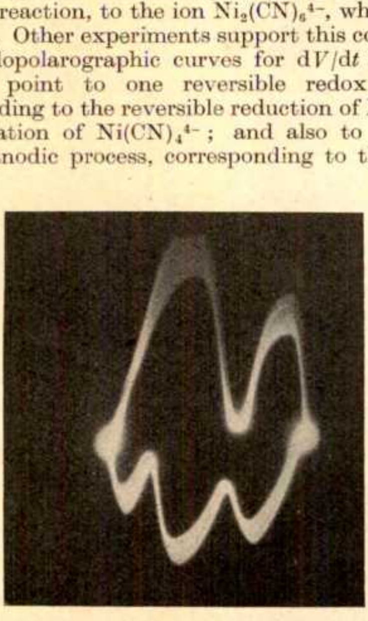


Fig. 1. Oscillographic curve for d*V*/d*t* versus *V* of $Ni(CN)_4^{2-}$ in 0·1 *M* sodium cyanide

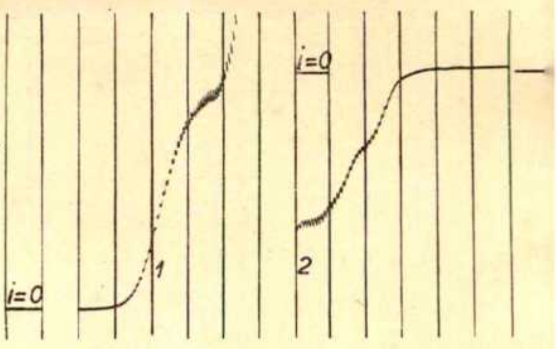

Fig. 2. Polarographic curves of $Fe(CO)_5$ and $Fe(CO)_4^{2-}$. Curve 1: $1{\cdot}5 \times 10^{-3}$ *M* $Fe(CO)_5$, from −1·2 V. (satd. cal. elect.), 205 mV./ absc. Curve 2: 1×10^{-3} *M* $Fe(CO)_4^{2-}$, from − 0·3 V. (satd. cal. elect.), 150 mV./absc. Electrolyte: 0·3 *M* $(CH_3)_4NCl$, absolute ethanol; nitrogen atm., *S* = 1·50

These experiments show that the ion $Ni(CN)_4$ is not reduced to the metal, as stated by Hume a Kolthoff[3], but to the ion $Ni(CN)_4^{4-}$, which is quick inactivated by a chemical reaction. Partial depositi of metallic nickel was observed only in acid solution The decomposition of the ion $Ni(CN)_4^{4-}$ in acid sol tion is caused by the tendency to form undissociate molecules of hydrogen cyanide.

The complexes of nickel (II) with dipyrid ethylenediamine, pyridine, ammonia and chlorid (in 5 *M* calcium chloride), were also shown to primarily reduced to zero-valent complexes of nick which are very rapidly decomposed to the metal oxidized to a higher oxidation stage. The life-ti of these zero-valent complexes is shorter than 0·01 se

From the study of nickel (II)-complexes, it follow that the formation of zero-valent complexes as primary product of electrode reaction is very probab in the reduction of the complexes of all transiti metals in oxidation stage + 2 with ligands which a not easily reducible. By the assumption of t formation of low-valent metal complexes, man catalytic effects of transition metals at the droppi mercury electrode, especially the Brdička reactio can be explained.

The stable zero-valent metal complexes wi *d*-orbitals not fully occupied by electrons localize in the metal atom can be further reduced at t dropping mercury electrode. An example of th behaviour is the reduction of iron pentacarbon which gives in ethanolic solution a well-develope reduction wave at − 1·7 V. (satd. calomel electrod (Fig. 2), followed by a large catalytic current at − 2 The height of the reduction wave corresponds to tw electrons for each iron atom. The product of t reduction is the ion $Fe(CO)_4^{2-}$, as was demonstrate by polarography with the Kalousek commutato The ion $Fe(CO)_4^{2-}$ is oxidized at the droppi mercury electrode in two successive steps (Fig.

some compound of zero-valent iron different from $e(CO)_5$ and $Fe_3(CO)_{12}$, as could be again demonrated by the Kalousek commutator.

This work will be described in detail elsewhere.

Improving the Characteristics of the Cyclotron Beam

REPORTS[1] of existing fixed-frequency cyclotrons dicate that near the maximum energy the ratio etween internal and external beam current is about ve to one, with the maximum current limited by eating of the septum by the stray beam. If the ternal beam could be more accurately aligned at e deflector and the stray beam removed, a larger xternal beam, better focused and with less energy-read, could be produced.

In the cyclotron, groups of particles leaving the n source become bunched in phase[2] and, given a able dee voltage, would follow nearly the same ath, arriving at the deflector after the same number turns. It is not usual to provide such stability, d many cyclotrons operate with quite a large mains pple. This produces a range of conditions at the eflector. For example, if there is a 6 per cent ripple the dee voltage, different groups of particles may between 66 and 74 turns. The energy and position particles within a single group are nearly the same. ue to precession of the particle orbits, however, e energy and position, and hence the extraction ficiency, may differ widely from one group to the xt.

Theory indicates that stabilization of the dee ltage to some 0·25 per cent would improve the aracteristics of the beam. The reduction in both ergy-spread and angular spread would then make easier to focus on remote targets, while selection the optimum particle group would give increased traction efficiency. There would be a further lvantage; a beam which follows a single path to e deflector makes it possible to place beam-defining its on the dee interface. By intercepting the stray articles, particularly those which would strike the des of the deflector, these slits ould collimate the beam and crease the extraction efficiency ill further.

A vertical slit has been tried ear the ion source on the Medal Research Council's 45-in. clotron and found to produce a rresponding narrowing of the eam at larger radii. The sides the slit can be made to interpt any portion of the first rn without impeding the suceding one, while the proximity the slit to the dees seems to ve no adverse effects. It is exected that in the final arrangement the slit near the ion source will be about ¼ in. wide by ¾ in. high and situated at 1¼ in. radius, with a second slit ⅛ in. wide, giving finer adjustment, placed just before the deflector. The beam current striking the two sides of this second slit could provide a convenient way of stabilizing the voltage.

The theory, which will be submitted for publication elsewhere, is based upon numerical plots of the first turns, precession calculations, study of the extraction conditions, and upon calculations[3] on the phase excursion through the machine. Some confirmation of the correctness of the theory is apparent in a report[4] on experiments with the internal beam of the University of Birmingham cyclotron. In this report stops are suggested for the reduction of beam pulse-length.

This work was done in connexion with the construction of the Medical Research Council's 45-in. cyclotron. I wish to thank Mr. J. W. Gallop for his interest and encouragement and also Mr. D. D. Vonberg and Mr. P. J. Waterton for many helpful discussions.

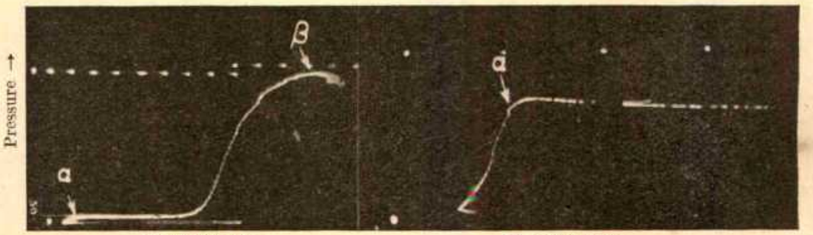
Adsorption Spectrum of Nitrogen on Tungsten

IT has recently been shown[1] that even at low coverages of a fraction of a monolayer, nitrogen is simultaneously adsorbed on tungsten in different states of binding, of which three have so far been isolated. The temperatures above which these individual species are unstable have been estimated semi-quantitatively as 800° K. for state α, 2,000° K. for β and 200° K. for γ. In order to define the spectrum of binding energies of the molecular species adsorbed on the surface, it is necessary to measure the concentration of adsorbed entities as a function of sorbent temperature. We have now been able to do this by a simultaneous recording of the rise in pressure and the increase in electrical resistance when the tungsten



(*a*) (*b*)

Fig. 1 (*a*). Desorption of nitrogen from tungsten with increasing temperature; filament initially at 298° K. Temperature range 298°–2,000° K. The instantaneous pressure is proportional to the amount of gas desorbed

(*b*). Desorption of nitrogen from tungsten initially at 298° K. Temperature range 298°–1,000° K

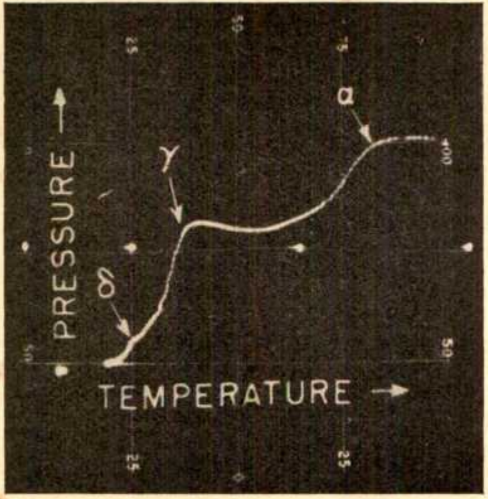


Fig. 2. Desorption of nitrogen from tungsten filament initially at 80° K. Temperature range 80°–750° K.

wire sample is heated in a flash-filament cell. Since the variation of electrical resistance of tungsten with temperature is known, the flash filament can be used both as adsorption sample and resistance thermometer.

In our system the pressure is monitored by an inverted ion gauge, the ion current from which is amplified with a vibrating-reed electrometer and displayed as ordinate on a cathode-ray oscilloscope. The adsorption filament is made one arm of a 10-kc./s. bridge, so that a change in filament temperature results in an unbalance which can be recorded on the abscissa of the oscilloscope[2]. Fig. 1 shows the resulting pressure vs. temperature plot for nitrogen adsorbed on a tungsten filament initially held at 298° K.; here the increase in the pressure (above the base line) corresponding to a given temperature is proportional to the total number of molecules evolved up to that temperature. Two regions over which desorption occurs are very clearly defined. After an initial evolution of gas only slightly above room temperature (the α-peak), desorption stops; for the initial stages of adsorption the material in the chemisorbed β-peak only begins to be evolved at 1,400° K., and is completely removed at 1,900° K. Fig. 1*b* gives an enlarged view of the low-temperature region of the burst, showing the α-peak alone, desorption of which appears to be complete at 650° K.

The details of adsorption in states of low binding energy are revealed in Fig. 2, showing a pressure vs. temperature trace for a filament cooled with liquid nitrogen to an initial temperature of 80° K. It appears that in addition to the α- and γ-peaks previously reported[1], a fourth level, δ, contributes significantly to adsorption at this low temperature. The temperature-ranges over which evolution of gas occurs are: level α, 300–650° K.; β, 1,400–1,900° K.; γ, 140–250° K.; δ, 100–140° K. We estimate a heat of desorption of approximately 85 k.cal. for nitrogen in state-β; the interactions in the other levels are significantly lower, and for γ and δ are presumably of the same order as commonly found in physical adsorption.

It has already been shown that nitrogen in state-α does not appear to participate significantly in the increase in population of state-β which can be observed with time[1]. Preliminary measurements which will be reported in greater detail at a late date, indicate that at $T = 80°$ K. there is no significant exchange between levels γ and β, but tha exchange between δ and the other levels does occur

The Prefix 'Nor' in Chemical Nomenclature

In his review of the new edition of "The Extra Pharmacopoeia" (Martindale), Vol. 2, Prof. J. H Gaddum (*Nature*, Feb. 25, p. 350) states, "surely *no* means 'N ohne Radikal' and not 'the next lower homologue' ". I have seen this explanation of the prefix 'nor' given several times in medical publications bu never in a chemical text-book, and I suspect tha "N ohne Radikal" is a mnemonic invented by a German pharmacologist to assist his students to remember the constitutions of *nor*adrenaline, *nor*ephedrine and similar compounds. However thi may be, the fact remains that the prefix *nor* is used for many compounds which contain no nitrogen a all; for example, *nor*pinic acid, *nor*œstrone, *nor*equilenin, etc. The statement made in Martindale i therefore perfectly correct.

It might be, of course, that this is simply an extension of the original use of the prefix 'nor', which certainly does not appear to be derived from Latin or Greek.

A. M. WOOLMAN

Eichenstrasse 7,
Arlesheim.

THE first use of the prefix 'nor' appears to be in a paper by Matthiessen and Foster[1] published in 1868 They were studying the nitrogen-free substance opianic acid formed by the oxidation of narcotine and obtained evidence that it contained two methy groups. They had used the term 'normal opianic acid' to mean the completely demethylated compound, and they then used the contraction 'methyl noropianic acid' for the monomethyl derivative Since that time the prefix has generally been used to denote the replacement of one or more methy groups by H, or the disappearance of CH_2 from a carbon chain, but its use may leave the resulting structure in doubt. I apologize for supporting a false etymological theory.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or efore the dates mentioned:

Lecturer in Engineering—The Registrar, University College, ardiff (June 8).

Lecturer in Mathematics, and a Lecturer in Physics, at Fourah Bay College, Sierra Leone—The Secretary, Advisory Committee on olonial Colleges, 1 Woburn Square, London, W.C.1 (June 8).

Assistant Experimental Officer (with a university degree in otany, zoology or microbiology and some training in chemistry) in he Marine Laboratory, Aberdeen, for duties which consist of the aintenance of algae cultures and assistance in research on the physiol-ogy of marine algae—The Establishment Officer, Scottish Home epartment, Room 364, St. Andrew's House, Edinburgh 1 (June 9).

Assistant Experimental Officer (with G.C.E. advanced level in athematics and physics, and an interest in the mathematical treat-ent of data) in the Department of Scientific and Industrial Research, Ditton Laboratory, near Maidstone, Kent, for work on ngineering and physical problems of refrigeration applied to food reservation—The Ministry of Labour and National Service, Tech-ical and Scientific Register (K), 26 King Street, London, S.W.1, uoting C.359/6A (June 9).

Lecturers (Grade II) (2) in the Department of Physics—The egistrar, The University, Birmingham 15 (June 9).

Physicists (2) (one with experience in electronics and the other radiotherapy), to work in a laboratory engaged in experimental nd routine work for the medical staff—The House Governor, King's ollege Hospital, Denmark Hill, London, S.E.5 (June 9).

Laboratory Steward in the Department of Physics at the niversity College of Rhodesia and Nyasaland—The Secretary, Inter-niversity Council for Higher Education Overseas, 29 Woburn Square, ondon, W.C.1 (June 11).

Lecturer and Assistant Lecturer (with special qualification in organic chemistry) in Chemistry—The Registrar, The University Manchester (June 11).

Lecturer in the Department of Mechanical Engineering—The Registrar, The University, Leeds 2 (June 11).

Research Student (with an honours degree in sociology, psychology or anthropology) to undertake research on educational problems in the Centre for the Study of Education—The Registrar, University College of the West Indies, Mona, Jamaica (June 11).

Research Assistant (preferably with an honours degree in botany and specialized in mycology) for work on potato gangrene—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (June 15).

Tutorial Students in Biochemistry, Botany, Civil Engineering, Geology, Mathematics, Physics, Physiology and Zoology—The Registrar, King's College, Strand, London, W.C.2 (June 15).

Assistant Librarian (graduate in pure or applied science and some experience in a scientific or technical library) in the Science and Technology Section of the University Library—The Librarian, The University, Edmund Street, Birmingham (June 16).

Biochemist or Organic Chemist (with either medical qualifications or a suitable chemistry degree) in the Pathology Division of the Pneumoconiosis Research Unit of the Council for Scientific and Industrial Research—The Director, South African Institute for Medical Research, P.O. Box 1038, Johannesburg, South Africa (June 16).

Lecturer in Psychology—The Joint Clerk to the University Court, College Gate, St. Andrews (June 16).

Reader in Applied Thermodynamics in the University and Head of the Department of Mechanical Engineering in Robert Gordon's Technical College—The Secretary, The University, Aberdeen (June 16).

Demonstrator in the School of Chemistry—The Registrar, The University, Leeds 2 (June 18).

Lecturer in Civil Engineering—The Registrar, The University, Sheffield (June 18).

Lecturer in Applied Mathematics—The Secretary, The University, 38 North Bailey, Durham (June 20).

Inorganic Chemist or Fuel Technologist (with a university honours degree in science with inorganic chemistry as a major subject or in fuel technology, and preferably with research experience) in the Coal Research Section, Commonwealth Scientific and Industrial Research Organization, North Ryde, Sydney, N.S.W., Australia, to undertake research into problems relating to dew-point and deposit-forming phenomena connected with the burning of Australian coals as part of general investigations into the efficient utilization of these coals—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (June 22).

Demonstrator in the Department of Geology—The Registrar, University College of North Staffordshire, Keele, Staffs (June 23).

Experimental Officer (graduate in botany with an ecological background and experience or special interest in field botany and natural history, or equivalent qualifications) as Assistant to the Regional Officer, East Anglia, based at Norwich, for duties which include assisting with biological surveys and management of nature reserves and other sites, liaison with Naturalists, Local Authorities, landowners and others, with some administrative work concerning general inquiries, conservation problems, issue of permits, etc.—The Establishment Officer, The Nature Conservancy, 19 Belgrave Square, London, S.W.1 (June 25).

Assistant Lecturer or Lecturer (with a degree or diploma in horticulture and sound practical experience) in Horticulture, at Canterbury Agricultural College, University of New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (June 30).

Assistant or Lecturer in Statistics—Joint Clerk to the University Court (University of St. Andrews), Queen's College, Dundee (June 30).

Lecturer in Theoretical Chemistry—The Registrar, University College of North Staffordshire, Keele, Staffs (June 30).

Lecturers (3) in Microbiology—The Registrar, The University, Birmingham 15 (June 30).

Senior Fellow in the Department of Geophysics, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (June 30).

Assistant Director of Research in Chemical Engineering—The Secretary of the Appointments Committee, Department of Chemical Engineering, Tennis Court Road, Cambridge (July 7).

Chair of Physics in the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (July 15).

Lecturer in Biochemistry; Lecturer in Psychology; Lecturer in Organic Chemistry; and a Lecturer in Physical Chemistry—The Registrar, University of Adelaide, Adelaide, South Australia (July 16).

Senior Professional Officer (with a university degree in science or engineering or equivalent qualification, and a minimum of four years research or industrial experience in refractories or ceramics) for duties which are concerned with the testing and investigation of ceramic materials of South African origin—The Director, Government Metallurgical Laboratory, University of the Witwatersrand, Milner Park, Johannesburg, South Africa (July 31).

Senior and Junior Research Fellows (with a first- or second-class honours degree in an appropriate subject, and able to show evidence of a very high standard of ability in research) at Government Scientific Establishments for research into subjects of importance to H.M. Government—Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4567/56 (October 31).

Assistant, Grade A, to teach pure and applied mathematics; and an Assistant, Grade A, to teach physics—The Principal, Technical College, Queen Street South, Huddersfield.

Assistant Lecturer in Physics (Grade B); a Lecturer in Mathematics, and an Assistant Lecturer in Mathematics (Grade B)—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3

Biochemist, to work on meat; and a Chemist and Physicist, to work on fats—The Director of Research, British Food Manufacturing Industries Research Association, Randalls Road, Leatherhead, Surrey.

Chair of Aircraft Economics and Production—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks.

Deputy Director (with a good honours degree in metallurgy and prepared to live in the Cambridge area) of Research—Director of Research, British Welding Research Association, 29 Park Crescent, London, W.1.

Hospital Physicist (Senior grade) in the Department of Radiotherapy, Essex County Hospital, Colchester, for work with X-ray therapy apparatus and radium—The Group Secretary, Hospital Management Committee, 14 Pope's Lane, Colchester, Essex.

Laboratory Assistant (with some skill in glass-blowing)—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Lecturer in Agricultural Chemistry (Animal Nutrition), and a Lecturer (with a degree in science or agriculture) in Agricultural Zoology—The Bursar, Harper Adams Agricultural College, Newport, Salop.

Lecturer (with good academic qualifications and experience in the food industry) in Food Science—The Secretary, Royal Technical College, Glasgow.

Mathematicians (with, or obtaining, a first- or second-class honours degree) at various Ministry of Supply Experimental Establishments, for work in numerous fields of interest, including aerodynamic and structural problems arising in supersonic flight; application of mathematical techniques to control and heat transfer problems of guided missiles; radio propagation; application of high-speed computing techniques to fluid dynamics and solid-mechanics, etc.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.198/6A.

Nuclear Physicist (Group Leader) (with a first-class honours degree in physics and research experience in the study of ionized gases), to lead a team in the field of controlled thermonuclear reactions—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 1165/34.

Research Assistant (with qualifications in mathematics, physics or chemistry, and preferably with experience of large-scale computing) in the Department of Inorganic and Structural Chemistry, to be a member of a small group engaged in preparing programmes for, and carrying out, extensive crystallographic and other scientific calculations on electronic digital computers—Prof. E. G. Cox, School of Chemistry, The University, Leeds 2.

Research Scholars and Fellows in the Textile Department—The Principal, Technical College, Bradford 7.

Senior Lecturer in Physics—Northern Polytechnic, Holloway, London, N.7

New Books

Electromagnetically Enriched Isotopes and Mass Spectrometry

Edited by M. L. Smith, *Atomic Energy Research Establishment, Harwell.*

This volume contains the proceedings of the Conference on Electromagnetically Enriched Isotopes held at Harwell in September 1955. The thirty papers are published in full, together with the ensuing discussions, and fall into three main categories which can broadly be described as follows: First there is illustrated the great range in the scale of the work from the small analytical mass spectrometers, to the large mass separators which provide gramme samples of the isotopes of all the elements for general distribution. Secondly, there are accounts of two approaches to the study of nuclear structure and reactions, one of which involves irradiation of separated isotopes followed by examination of the products, and the other irradiation of a natural element and then direct mass assignment and examination. Finally, several papers review work in a number of fields using enriched isotopes and assess the trends for the future. Price 45s.

Quantitative Methods of Organic Microanalysis

by S. J. Clark, Ph.D., A.R.I.C., *British Nylon Spinners Ltd.*

This book has been written for the practising microanalyst, to provide working details of modern methods of organic microanalysis which have proved reliable in use in both academic and industrial laboratories. Many of the techniques described are comparatively new and represent improvements over the older methods in respect of accuracy and precision, speed or simplicity: others enable determinations to be performed in a routine manner hardly possible ten years ago. Sufficient detail is included in the description of each method to allow the reader to set up and become proficient in its operation.

The determination of all the common elements and groups is described, together with those for which reliable methods have only recently been developed. Price 30s.

LECTURES AND COURSES

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

A Course of Six Lectures on "Properties and Industrial Applications of Powdered Materials" will be given by Dr. H. Heywood, M.I.Mech.E., M.I.Chem.E., on June 18, 19, and 20, 1956

Further information may be obtained from the Deputy Registrar, City and Guilds College, Exhibition Road, S.W.7.

UNIVERSITY OF SHEFFIELD

COURSES IN APPLIED MECHANICS

Graduates and others are invited to lectures, tutorial classes and practical work in Electronics, Stress Analysis, Plasticity Metrology, Gears, Servomechanisms, Lubrication, and Vibration Consideration given to individual needs Facilities for research work on specific problems.

Details from: Professor W. A. Tuplin, D.Sc., M.I.Mech E., the University, St. George's Square, Sheffield, 1.

NORTHERN POLYTECHNIC

SESSION 1956-57

ADVANCED COURSES IN

ELECTRONICS AND WAVEGUIDE PHYSICS

ELECTRICAL DISCHARGES IN GASES

SOLID STATE PHYSICS

Suitably qualified students can proceed to the M.Sc. degree of the University of London.

Session begins September 24, 1956

Also short lecture courses on

MICROWAVE VALVES, beginning October 2, 1956

PULSE TECHNIQUES, beginning November 5, 1956

Inquiries should be addressed to: Head of Department of Physics, Northern Polytechnic, Holloway, London, N.7. (Telephone: NORth 1686).

OFFICIAL APPOINTMENTS

COMMONWEALTH of AUSTRALIA

C.S.I.R.O. DIVISION OF BUILDING RESEARCH

RESEARCH ON PAINTING OF PLASTER SURFACES (APPOINTMENT NO. 390/238)

The Commonwealth Scientific and Industrial Research Organization invites applications for appointment to a research position at the Division of Building Research, Highett (near Melbourne), Victoria. In co-operation with the Paint Industry the Division is about to undertake an investigation into the problems associated with the painting of plaster surfaces, a matter of considerable importance to the building industry which will involve both basic and applied research The appointee will co-operate with another research officer who will be making a study of the chemical and physical characteristics of fibrous plaster. Contact will be maintained with manufacturers and some field work, requiring interstate travel, will be necessary. Applicants should possess a university honours degree in science, with chemistry as a major subject, and with post-graduate research experience. Experience in paint technology is preferable but not essential. Dependent on qualifications and experience, commencing salary will be determined within the range of Research Officer (£A.1,263 to £A.1,888 per annum) or Senior Research Officer (£A.1,998 to £A.2,273 per annum). By arrangement with the successful candidate the appointment would be considered either for an indefinite period or initially on a short term basis of three years First-class sea fares will be paid to Australia for the appointee and for his wife and family At the end of a short term appointment return fares will also be met by the Organization. The appointment is conditional upon a satisfactory medical examination and, for an indefinite appointment the successful applicant will be required to contribute to and receive benefits from, either the Commonwealth Superannuation Fund or the Commonwealth Provident Fund.

Applications, referring to Appointment No 390/238, and stating full name, date and place of birth, marital state, nationality, present employment, particulars of qualifications and experience, and of war service, if any, accompanied by the names and addresses of three referees and copies of not more than four, testimonials should reach the undersigned not later than July 7, 1956

W. IVES,
Chief Scientific Liaison Officer
Australian Scientific Liaison Office,
Africa House,
Kingsway, London, W C 2.

NATIONAL COAL BOARD

WEST MIDLANDS DIVISION

Applications are invited for the post of Assistant to the Divisional Chief Scientist in the grade of Senior Scientist (£1,700 to £2,000). Candidates should have good academic qualifications and experience in the organization of work programmes at a large industrial laboratory.

Applications to the Divisional Establishment Officer, National Coal Board, Himley Hall, Dudley, Worcs.

CAVENDISH LABORATORY

CAMBRIDGE

There are vacancies in the Meteorology Section for Research Students to work on problems relating to "Atmospherics." Maintenance allowances, at normal rates, will be available for persons with qualifications, e.g., a good honours degree in physics or electrical engineering, which would enable them to be candidates for research degrees.

For further information apply to the Meteorology Section, Cavendish Laboratory, Cambridge.

DURHAM COLLEGES IN THE UNIVERSITY OF DURHAM

Applications are invited for a Research Fellowship in Chemistry. The Fellow will be expected to carry out original work on a radiochemical topic in the Londonderry Laboratory for Radiochemistry. The Fellowship will carry an annual salary of £650 to £750, together with the benefits of the F.S.S.U. scheme and family allowances The appointment will begin at a date to be arranged, and will be tenable for two years with the possibility of an extension

Further details may be obtained from the Secretary, 38 North Bailey, Durham, to whom applications (three copies), together with the names of three referees, should be sent by June 16 1956 Candidates from overseas may send one copy only.

DURHAM COLLEGES IN THE UNIVERSITY OF DURHAM

Applications are invited for a Research Studentship in Radiochemistry. This Studentship, of the value of £300 per annum, is tenable for two years in the first instance, with possible renewal for a third year. Candidates should have a good honours degree in chemistry from a British university, but applications from candidates expecting to graduate in 1956 will be considered The successful candidate will be expected to undertake original research leading to a higher degree.

Further details may be obtained from the Secretary, 38 North Bailey, Durham, to whom applications (three copies), together with the names of two referees, should be sent by June 16, 1956.

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF AGRICULTURAL SCIENCES

Applications are invited from honours graduates or from candidates who expect to graduate this summer for the following Demonstratorships (a) Agricultural Botany, preferably with interest in Plant Physiology (b) Microbiology, with interest in Dairying or Soil Microbiology (c) Agricultural Chemistry, with qualifications in Agricultural Chemistry or Chemistry. (d) Agricultural Zoology, with qualifications in Agricultural Zoology or Zoology. Salary scale £350 by £50 to £400

Forms of application and conditions of appointment from Mr. H Pickbourne, Registrar.

BIOCHEMIST, RECENT GRADUATE, REquired for Department of Clinical Research, to assist in research programme relating to certain biochemical aspects of mental illness under direction of senior biochemist. Salary £500 to £600, according to qualifications and experience—Applications, stating qualifications, age, and, in the case of National Servicemen, approximate date of release, should be sent to the Physician Superintendent, Crichton Royal Mental Hospital, Dumfries.

THE RESEARCH INSTITUTE (ANIMAL Virus Diseases), Pirbright, Surrey, invite applications for a post of Research Assistant (female). Applicants should have a degree in chemistry or physics and an interest in the physical chemistry of biological systems. The post is superannuable and the salary in accordance with the Assistant Experimental Officer grade, which is £429 at age 21 rising by ten increments to the maximum of £634 per annum.—Applications, accompanied by the names of three persons to whom reference can be made, should be addressed to the Secretary

CHEMISTS

required by

THE ATOMIC WEAPONS RESEARCH ESTABLISHMENT, ALDERMASTON BERKSHIRE

in the following grades

Chemists Basic Grade (Ref. 1159/34) t control the chemical process and gas purification production plants in the Chemic Engineering Branch working on a shift basis Candidates should hold A.M.I Chem.E. o A R.I.C. or have exempting qualifications alternatively they should have an honour degree in chemistry or chemical engineering Some previous experience of plant contr work is desirable but not essential. Salar £766 (at age 25) to £1,050 (at age 34 o over) to £1,199 per annum.

Experimental Officers/Assistant Experimental Officers (Ref. 1160/34) to join Research and Development team engage on a new field of applied chemical researc and technology. The minimum qualifica tion is higher national certificate chemistr or equivalent; applicants for the Experimental Officer grade should be at least 2 years of age. Candidates should have ha good experimental experience in the inorganic field and preferably also on pilot plan scale operation.

Salary, Experimental Officer, £846 t £1,040 per annum; Assistant Experimenta Officer £353 (at age 18) to £460 (at age 21 to £756 per annum. At present the rate for women are slightly lower. Contributio Superannuation Scheme. Married officer now living outside the Establishment' transport area will be eligible for housin on one of the Authority's estates; alternatively assistance towards legal expenses incurred in house purchase may be available Until housed a lodging allowance may b payable

Requests for application forms, by post card, to Senior Recruitment Officer at th above address, not later than June 11, 1956 quoting the appropriate reference number

CHARING CROSS GROUP

WEMBLEY HOSPITAL (134 beds)

Student Technician required for Patholo Laboratory (male or female). Salary and co tions in accordance with Whitley Council regtions

Apply, with age, experience, etc., to Se tary, Wembley Hospital, Wembley, Middlese

UNIVERSITY OF NOTTINGHA

DEPARTMENT OF ECONOMICS

Applications are invited for the appointn of Research Lecturer or Assistant Lecturer Statistics. Salary scales Lecturer, £650 by to £1,350; Assistant Lecturer, £550 by £50 £650. Superannuation and children's allowan Form of application and conditions of app ment from the undersigned.

H PICKBOURN
Regist

THE BRITISH SOCIETY FOR RESEAR in Agricultural Engineering has vacancies for Assistant Experimental Officers in the Horti tural Engineering Department, one to work heating and ventilating problems, the other cultivation machinery problems. Inter.B. H N C. or equivalent essential, and industrial research experience in engineering or physics sirable. Salary scale £382 at age 20 rising £706, with starting salary limited to £559 at 26.—Application forms from Secretary, N.I.A Wrest Park, Silsoe, Beds.

SENIOR TECHNICAL ASSISTANT quired for development work in Bacteriolo Laboratory. Duties will include supervision routine technical work and training of tech staff. Salary on scale £500 to £700 per annun Apply, by letter, to Professor Todd, Royal T nical College, Glasgow.

THE BRITISH SOCIETY FOR RESEAR in Agricultural Engineering has vacancy for Sc tific Officer for laboratory work on physical engineering problems associated with use of techniques in crop conservation. First- or sec class honours degree essential. Salary sc £514 to £933; starting pay according to age experience. F.S.S.U.—Application forms f Secretary, N I.A.E., Wrest Park, Silsoe, Bed

Half-tone printing plates
with an ordinary studio camera

It is now possible to make half-tone printing plates with an ordinary sheet-film camera. 'Kodalith' Autoscreen Ortho Film has the half-tone dots incorporated in the emulsion, making process cameras and half-tone screens unnecessary.

Autoscreen Film can be used with pre-sensitized metal plates to make half-tone or combination line/tone plates for reproduction by office printing machines. Type matter and line drawings can be exposed at the same time as photographs or wash drawings.

Please send for details.

1. Make the normal detail exposure.
2. Flash with yellow light for contrast control.
3. Develop, with controlled agitation.

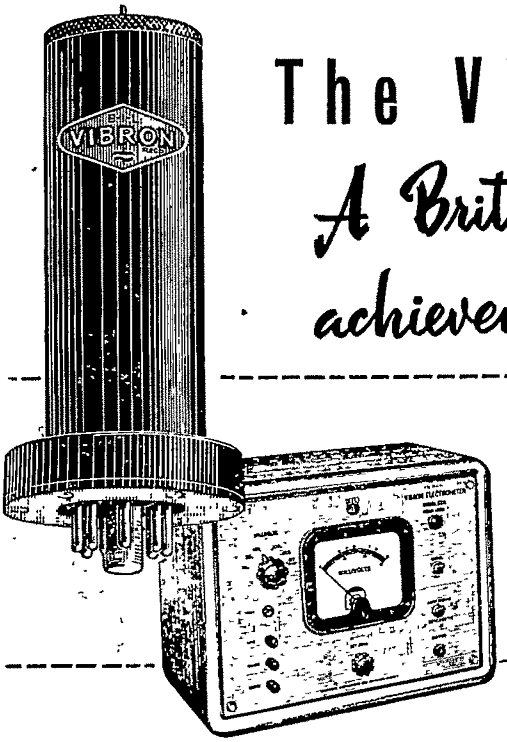
Kodalith
Autoscreen
Ortho Film

Kodak Limited, Industrial Sales Division, Kodak House, Kingsway, London, W.C.2.

'Kodalith' is a registered trade-mark.

The VIBRON

A British achievement!



The Vibron Electrometer is a new instrument for measuring, with exceptional stability, very small currents from a high impedance source.

The 'heart' of the instrument is the E.I.L. VIBRON vibrating condenser unit, a precise electro-mechanical device which performs some 50 times better than the conventional electrometer valve.

The Vibron Electrometer is being used for ionisation current measurements, as an ultra stable pH meter and as a very high resistance megohmmeter.

Manufactured under British Patent No. 550610 and Patent Application No. 35637/54

CHEMICAL LABORATORY SCIENCE COLLEGE Date 16.7.56

THE COLONIAL DEVELOPMENT CORPORATION

HE annual report of the Colonial Development Corporation for the year ended December 31, 55*, is cast in the staccato form that has char-erized the report since Lord Reith assumed the irmanship of the Corporation; but this year, for first time, the accounts show a surplus of £409,233 er paying all outgoings, including £307,000 Colonial ice interest.

Ten new projects were initiated by the Colonial velopment Corporation during the year, and, h the completion of the Barton Ramie and rongo investigations, and the appointment of receiver for the Falkland Islands Freezer Co., l., there are sixty-three continuing projects and estigations compared with fifty-six in the previous ar, representing a total capital of £54·8 million. these projects, eighteen, representing £7·5 million, in the Caribbean; seven (£15·4 million) in the r East; thirteen (£13 million) in East Africa; (£6 million) in Central Africa; eleven (£9·86 llion) in the High Commission Territories; and ht (£2·9 million) in West Africa. Functionally, elve projects and 20 per cent of deployed capital December 31, 1955, were in agriculture; six and l per cent in animal products; six and 6·9 per cent factories; one and 0·3 per cent in fisheries; five d 12 per cent in forestry; one and 0·7 per cent in tels; ten and 13 per cent in minerals; seven and ·9 per cent in property and housing; six and ·3 per cent in power; and eight and 4·5 per cent transport and communications.

On direct projects and subsidiary companies, the rporation had a net operating profit of £113,165 ring the year, in spite of the disappearance of ulanga profits of £216,718 in 1954 with the sale the Corporation's controlling influence from nuary 1, 1955. The 'redding-up process' is now tually completed, and the Corporation by and large free to devote its energies to constructive purposes volving normal commercial or calculated risks. ie 'Special Losses' were assessed on December 31, 55, at some £8 million, and it is clear that the vernment must now face the outstanding financial ues involved in dealing with these losses incurred fore the Corporation was built up. The Corporation oposes to disregard this Special Losses Account in justing its policies to meet the requirement of the verseas Resources Development Act that it should y its way taking one year with another, and it w suggests that the whole of this Account—not erely a part—should be accepted as eligible for terest waiver, and that this should be done by nverting the £8 million into equity capital in cordance with the precedence of the International ınk for Reconstruction and Development and the ternational Finance Corporation.

This is not the only way in which the Government uld help to promote a more vigorous policy, nor is it the only point at which there is a clash between the Corporation and the official view. The latter has interpreted the Overseas Resources Development Act so as to make *ultra vires* several projects for housing and road development in Singapore and Malaya, Kenya, Nyasaland, Southern and Northern Rhodesia and West Africa, involving more than £7·5 million; but on legal advice the Corporation has declined to accept the official legal view, and awaits the validating and enabling legislation promised by the Secretary of State. The Corporation in this report also points to the desirability of co-ordinating its funds with Colonial Development and Welfare Funds, suggesting that the Government might meet essential but financially unremunerative projects, leaving the remainder to the Corporation and its partners. Only exceptionally should the Corporation undertake work of great potential benefit but doubtful profitability.

In spite of its staccato phrases, the report is thus a challenge to realistic thinking and planning of such resources as Britain is able to devote to the economic development of the dependent territories of the British Commonwealth. It is the duty of the Colonial Development Corporation to assist such development and with special regard to the interests of the inhabitants of those territories. The Corporation is not, however, responsible for comprehensive planning, or for social services such as health and education. These, the report suggests with reason, are, or should be, financed from Colonial Development and Welfare Funds or other government funds. Similarly, government plans should include such services as power, communications and housing. The Corporation's terms of reference are commercial, and profitability is a decisive factor in the selection of projects and the method of executing them. The Corporation should only be expected to help in the capital development of basic services when no other means of finance is available.

The formulation and acceptance of clearly defined policies on such lines would go far to establish the Corporation on a satisfactory commercial basis; but more important, it would provide the Corporation with the assurance of continuity which it seeks, and the clear definition of fields of work which are as essential for harmonious co-operation as they are for preventing wasted effort and overlapping. As is well emphasized, development in the dependent territories of the British Commonwealth is always a dynamic process in which social conditions and agricultural and industrial techniques are continually changing. The report points out that the tropical territories in which the Corporation mostly operates can scarcely look forward to more favourable economic conditions than in 1955. The Corporation itself benefited from the high prices of rubber and improved prices for hardwoods, but the two copper projects will not start producing until late in the present year. Prices of other Corporation products, such as hemp, rice, hide and bananas, tended to drop, and synthetic substitutes are threatening raw materials traditionally grown in the tropics, among which the Corporation is directly interested in rubber, hemp, tung oil, and, through tanning materials, in leather, though its interest in ramie has ceased. Moreover, the production of foodstuffs in developed countries can be so increased by application of fertilizers and use of mechanical equipment as to undercut producers in less-developed and more remote lands.

---

* Colonial Development Corporation. Annual Report and Statement Accounts for Year to 31.12.55. Pp. v+55. (London: H.M. tionery Office, 1956.) 2s. 6d. net.

These are all factors of which the Corporation must take account in attempting to assess the profitability of projects in ten or twenty years time, and in selecting projects accordingly. Increasing association with local people in such projects through smallholding and co-operative schemes will not make decisions easier ; but the Government, by taking the financial decisions suggested above and by delineating more carefully the spheres of responsibility, could undoubtedly help the Corporation, to raise the standard of living in these areas. Even more directly, Government policy could contribute to provide assured markets for the efficient grower of tropical produce ; and the dissolution of the Overseas Food Corporation on March 31, 1955, places even greater responsibility in this connexion on both the Colonial Office and the Tanganyika and other African Governments.

CHEMISTRY AND BIOCHEMISTRY OF FATS

The Lipids

Their Chemistry and Biochemistry. By Prof. Harry J. Deuel, Jr., Vol. 2 : Biochemistry—Digestion, Absorption, Transport and Storage. Pp. xxvi + 919. (New York : Interscience Publishers, Inc. ; London : Interscience Publishers Ltd., 1955.) 25 dollars.

Fat Metabolism

A Symposium on the Clinical and Biochemical Aspects of Fat Utilization in Health and Disease. Edited by Victor A. Najjar. Pp. viii + 185. (Baltimore : Johns Hopkins Press ; London : Oxford University Press, 1954.) 36*s*. net.

The Chemistry of Lipids of Biochemical Significance

By J. A. Lovern. (Methuen's Monographs on Biochemical Subjects.) Pp. xiii + 132. (London : Methuen and Co., Ltd. ; New York : John Wiley and Sons, Inc., 1955.) 8*s*. 6*d*. net.

THE collection of the greater part of the available information in the vast and rapidly developing field of lipid biochemistry and its integration into a readable text are a remarkable achievement. It is not, however, possible to be both comprehensive and critical over such a wide field. The late Prof. H. J. Deuel, jun., in "The Lipids : Their Chemistry and Biochemistry" (Vol. 2), chose the former course. All the main contributions on the digestion, absorption, transport and storage of lipids are recorded in this book. Where differences of opinion exist, the views of each side are clearly and fairly presented. The author was one of the most active contributors to new knowledge in this field, and he had definite views on most of the problems discussed in this work. These are indicated, but are not forcefu imposed ; the reader is left to formulate his o conclusions. This is an excellent book for the m advanced student. It is likely to serve as a standa work in this field for many years.

The symposium on "Fat Metabolism", edited V. A. Najjar, is an entirely different type of wo which consists of a series of short lectures by leadi authorities. There are eleven main contributio These include papers by H. H. Gordon and J. Ma on obesity, and a contribution on the clinical aspe of hyperlipæmia by L. E. Holt. H. C. Meng c scribes the preparation and use of fat emulsions intravenous alimentation, and the role of the lipæn clearing factor in fat transport is considered C. B. Anfinsen. Fatty-acid oxidation and synthes lipogenesis *in vitro* and the role of coenzyme A such reactions form the subject of three communi tions by A. L. Lehninger, S. Gurin and F. Lipmar respectively. Phospholipid synthesis, by A. Ko berg, and cholesterol metabolism in relation atherosclerosis, by R. G. Langdon, complete remarkable collection of papers. Four contributic to discussion are also given. The only other asp that might perhaps have been included with so advantage is the role of the intestine in fat me bolism. This book is an excellent introduction current problems in fat metabolism, especially those interested in the medical aspects. As will expected, each contribution is both authoritati and lucid.

Dr. J. A. Lovern's monograph on the "Chemis of Lipids of Biochemical Significance" is a conc account of the more important background knowled required for biochemical studies in this field. T first chapter is concerned with the structure of lipi a matter that is much under discussion at the prese time. A useful section on separation and analy follows, which reflects the extensive experience t author has had in this field. Having dealt with t study of separated lipids, the forms in which th occur in the tissues, with special reference to lip proteins, and their turnover, are discussed at so length. Finally, a brief chapter on the functions lipids concludes a record of the main features current problems in lipid chemistry that should pro useful to any biochemist.

A. C. FRAZER

POWER AND ENERGY FROM TH WINDS

The Generation of Electricity by Wind Power

By E. W. Golding. (Spon's Electrical Engineeri Series.) Pp. xvi + 318 + 28 plates. (London : and F. N. Spon, Ltd., 1955.) 50*s*. net.

BEFORE the industrial potentialities of nucle fuels began to be clearly realized, the Wi Power Committee of the Electrical Research Assoc tion intensified its study of the winds as a supp mentary source of synchronous electric power. all-important impelling factor was the scarcity coal for the generation of electricity ; but importar was attached to an experiment made in the Unit States in which a 1,200-kW. wind-driven generat had been operated successfully in parallel with major electricity supply system. The Americ wind turbine had indeed failed mechanically after w hundred hours of operation; but it had shown at there is no physically insurmountable obstacle the way of developing wind-driven generators of latively large capacity.

Denmark, France, Germany, Italy and the U.S.S.R. ave also done work of great interest in assessing e energy-producing prospects of wind-power and constructing and devising wind-driven generators. ast experience was carefully reviewed. The fact at some ten thousand corn-grinding mills had been erforming a valuable function in Great Britain prior the development of the steam engine was, and is, gnificant. It was estimated that there are several undred sites in Britain which might be used for stablishing wind-driven electric generators of capa-ities of the order of 1,000 kW. each.

The author of this book, Mr. E. W. Golding, was harged with the tasks of examining the problems f measuring and harnessing the power and energy f the winds at suitable sites. He and his staff roceeded to their work with due expedition and great nthusiasm. Precise and convenient means of easuring wind velocities over the wide range ncountered in practice were developed and applied t a sufficient number of sites to obtain the data equired by aerodynamic experts, the potential uilders of efficient wind turbines.

It so happened that the development of heli-opters, on one hand, and of jet aircraft, on the other, roused the interest of propeller designers in the wind heel, which promised to provide a new outlet for heir factories. As a result, John Brown and Co., td., produced a 100-kW. machine for the North of cotland Hydro-electric Board which is installed on osta Head, Orkney, while the Enfield Cable Co. roduced through De Havilland (Propellers), Ltd., n Andreau machine of the same kilowatt rating or the British Electricity Authority. The latter achine is still on a temporary site near St. Albans. hese two experimental installations cover almost he extreme range of types of wind wheel, electrical enerating plant and wind speed conditions. At osta Head, wind speeds approaching 100 m.p.h. are requently encountered and it is exceptional to have eriods approaching dead calm, whereas at St. lbans wind speeds seldom reach even 30 m.p.h.

No account of the performance of these plants as yet been published; but it is now doubtless ossible for the responsible parties to assess, more ealistically than ever before, what power and energy an be obtained from comparatively large wind-driven lectric generators. The work put into these two xperiments has been of the highest class in all espects. The firm of John Brown has experienced lmost every practical difficulty which can be ncountered, and the major burden has been borne y two resolute and competent men, as a supplement o their everyday occupations. They could give an pic account of their problems, which far surpass in ifficulty those of the earlier lighthouse pioneers.

Golding's book is interesting, informative and arnest. The author has deservedly gained a leading lace among the few who continue to maintain an ctive interest in wind-power. He provides excellent eferences to relevant literature from all countries. e does full justice to most of the foreign achieve-ents; but he might have made more effective use f the highly objective studies of Electricité de rance. He likewise appears to have overlooked he numerous wind machines in service on the coast f Portugal, near Lisbon. There one can see installations ranging from the original Don Quixote type to the most modern propeller types, indications of the suitability of the wind regime, on one hand, and of the local cost of electricity, on the other. Table 32 would have been far more valuable had he included the weights of materials of construction of the machine. I must, however, abstain from emulating Goethe's "Rezensent', and I therefore commend the book as being a most valuable and up-to-date source of reference.

In conclusion, I suggest that the attempt to produce large amounts of synchronous electrical power and energy from the winds is less realistic in present circumstances than a Belgian proposal to use medium- or small-power plants to generate energy partly in electrical form and partly as hot water not necessarily electrically heated. There are many farms and isolated communities which could be rendered more economic and habitable given these amenities. Production of machines of this class might be more generally useful than the procedure hitherto followed.

C. W. MARSHALL

PRINCIPLES AND APPLICATIONS OF PHYSICS

Principles and Applications of Physics

By Dr. Otto Blüh, in collaboration with Joseph Denison Elder. Pp. xiv+866. (Edinburgh and London: Oliver and Boyd, Ltd., 1955.) 45*s*. net.

BOTH in its aim, which is wider, and in its presentation of the subject, which seems more appropriate for reflexion and consolidation than for a serial course, this book differs from the conventional physics text-book. The standard is such that most of it could be understood by sixth-form boys, and it would be useful to students in the early stages of a university course in physics. The authors survey the subject as a whole, tracing the developments of the concepts of modern physics, and the interaction of new discoveries and scientific thought at different periods. This treatment should make it acceptable also to non-specialists and students of the humanities who (given some initial elementary grounding) seek a sound interpretation of physics; such readers, whom the authors have borne in mind, will find it both intelligible and in sympathy with their own outlook

The book is divided into ten parts. Part 1, on the methods of physics, contains some introductory mathematics. Parts 2–6 deal with mechanics, energy, fields of force, oscillations and waves, and thermodynamics. Each part groups together phenomena linked by a common principle—heat, electrical energy, and radiation as forms of energy, gravitation, electrostatics, and electromagnetism as fields of force, optics and acoustics with other examples of wave motion. The authors call this a phenomenological and mathematical approach, in which formal analogies are used. They are probably right; and it is certainly done well.

Parts 7–9, on the kinetic theory, particles, and atomic and nuclear physics, offer less scope for originality of treatment, and indeed by this time the really difficult part of the work is over. In its more recent developments physics deals either with particles that are easily pictured, or with symbols that are beyond any visualization; the apparently simple concepts of macroscopic physics are the elusive ones. Who can doubt, for example, that the picture shown of stationary waves around Bohr orbits was really in people's minds in the early days of wave-mechanics ? Or that this, in itself, is a much easier idea to understand than, say, the principle of virtual work, or even that notorious source of misunderstanding when it was first discovered, Ohm's law ? In directing attention to the quite different kind of mental effort needed to master the early fundamentals, the authors have really implicitly diagnosed the fault that hinders the progress of so many students, a feeling that physics began with the twentieth century. Needless to say, the rigours of modern physics are themselves explained here very clearly.

The title might almost suggest a bias towards applied physics, but in fact only representative applications are explained at all fully. These include the circulation of the blood, thermionic valves and radio circuits, frequency modulation, three-phase power supplies, the implications of recent red-shift observations with the 200-in. reflector, and many uses of radioisotopes. The numerous brief allusions to well-known applications are relevant. Most teachers, incidentally, would treat thermometry and electrolysis rather differently nowadays.

Part 10, on the scope and importance of the physical sciences, is rather more difficult to assess. I can only say that, if I had read a book of this kind as a student, I should have realized then that philosophy is something more than the extrapolation of a classical education ; and that, oddly enough, the term 'natural philosophy' means what it states. Among many issues discussed are the status of the term 'law' in the exact sciences, the fallibility of scientific method when taken beyond its proper province, and the general education of both the scientist and the non-scientist. It has been said that the way to broaden the general education of the physicist is by encouraging a thorough understanding of his subject, and its impact on people's minds and affairs. From this point of view the later chapters of the book are particularly valuable.

G. R. Noakes

LUMINESCENCE OF BIOLOGICAL SYSTEMS

The Luminescence of Biological Systems

Edited by Frank H. Johnson. (Proceedings of the Conference on Luminescence March 28–April 2, 1954, sponsored by the Committee on Photobiology of the National Academy of Sciences—National Research Council, and supported by the National Science Foundation.) Pp. xiv+452. (Washington, D.C.: American Association for the Advancement of Science, 1955.) 7 dollars.

The production of light by many living organisms is a very striking characteristic and has been recognized since the earliest times. Pliny observed the glowing of rotting wood, Aristotle had an account of the light emitted by putrefying fish, and Boyle in 1667 examined the luminescence of stored meat. The early papers of Paul Panceri in 1873 on *Pyrosoma*, *Pholas* and *Phyllirhoë* are classics.

This book is an account of the proceedings of the conference on luminescence, held at Asilomar, Pacific Grove, Calif., during March 28–April 2, 1954, and the papers and the main discussion of each are given verbatim. The first paper, a survey of luminous organisms. is by Prof. Newton Harvey, a pioneer i this field and celebrated for his classic and extensiv investigations into the subject of luminescenc This is a very lucid account of the state of the existin knowledge of the problem, with stimulating suggestions for further work. Methods are described wit a wealth of detail. Drs. R. S. Becker and M. Kash follow with a discussion of luminescence spectroscop involving the role of chlorophyll, and the electron state of this pigment which is concerned with th first reaction in the utilization of energy by the pigment system. The luminescence properties of porphyrin molecules are being studied by these worker with special reference to the chlorophylls, and th singlet-triplet split in molecules is considered.

Perhaps the most interesting and informativ chapter, at any rate for porphyrin workers, is that c C. Stacy French on fluorescence spectrophotometr He describes apparatus in detail, and follows up wit a most useful account of the absorption and fluorescence spectra of the chlorophylls and their derivative data which are not readily accessible in the literatur Wilhelmsen *et al.* have a paper on chemiluminescenc kinetics of the 2 : 3 dihydrophthalazine 1 : 4 dione and a mechanism for the reaction is proposed, base on the ionization, in basic solution, of the enol form shifting the equilibrium in their favour. Oxidatio of the ionized portion would then involve loss of th charge, and reaction with more oxygen would lea eventually to a molecule which, when excreted would emit light.

Two deeply interesting chapters are those dealin with the chemistry of *Cypridina* luciferin by Drs Tsuji, Chase and Harvey, and the biochemistry o firefly luminescence by Drs. McElroy and Hastings The first contains much detail regarding the preparation and purification of luciferin (chromatograph and electrophoresis) and a study of degradatio products. The second describes purification method for luciferin and luciferase from *Photinus pyralis*, an gives some properties of the luminescent system including the possible role of adenosine triphosphate The biochemistry of bacterial luminescence is ver fully discussed by Dr. Strehler, with some pointer as to the mechanism involved, which seems to includ the participation of reduced flavin mononucleotide Intracellular luminescence is introduced by Dr. Fran Johnson, the editor, and includes a study of th kinetics of bacterial luminescence *in vitro*.

From the biochemical mechanisms of luminescence the reader moves to the physiological control o luminescence, the subject of Dr. Nicol's paper which is further discussed and extended by Dr. Buck Dr. Nicol's main concern is with neurocontrol there are two effector systems, muscles and photocytes, which depend on one conductor system Oxygenation may be a limiting factor. The surve of luminous organisms of the Far East, by Dr Haneda, is a fascinating and most useful contribution it contains several very fine photographs. The symposium ends with two short papers, one on marine dinoflagellates by Dr. Ryther, and one by Drs. Haxo an Sweeney on bioluminescence in *Gonyaulax polyedra*.

The sequence of the contributions could be criticized ; for example, the papers on control of luminescence would have been more logically placed afte the papers on firefly luminescence, and the very fin survey of Haneda after the introduction by Harvey The paper is good, the print clear and the photograph have been reproduced well. There is a good index

G. Y. Kennedy

Proceedings of the International Conference of Theoretical Physics, Kyoto and Tokyo, September 1953

Held under the auspices of The International Union of Pure and Applied Physics. Organized by The Science Council of Japan, with the collaboration of Kyoto University and The Physical Society of Japan. Supported by U.N.E.S.C.O. and The Rockefeller Foundation. Pp. xxviii + 942. (Tokyo: Science Council of Japan, 1954.) n.p.

THE 1953 conference on theoretical physics in Japan was remarkable for a number of reasons: the wide range of topics treated by the eighty-four distinguished foreign visitors and the local participants; the fact that this was the first purely scientific international conference ever held in Japan; the hospitality bestowed on the fortunate guests; and the magnificence of this volume recording the proceedings. It all does full justice to the devotion accorded to theoretical physics in Japan, and the high achievement in the subject there.

The conference was concerned principally with the two broad domains of field theory and solid-state physics. In the former (Part 1 of the report), there was much deliberation on the various technical difficulties of non-local theory, intermediate and strong coupling theory, nuclear forces, etc. Part 2 is a shorter section on nuclear physics, mainly the shell model. The remaining, major portion of the volume comprises Part 3 on statistical mechanics, Part 4 on molecules and solids, and Part 5 on liquid helium and superconductivity.

Nearly as much space is devoted to discussions as to the actual papers, giving a picture of a lively and informal conference. Survey talks are an important feature, and altogether the book offers a valuable insight into the state of theoretical physics at the time, and the thoughts occupying the leading workers. However, this amounts largely to journalism, though on the grand scale, and already much water has flowed under the bridges of theoretical physics since the conference.

Yearbook of the United Nations, 1954

Pp. xii + 656. (New York: United Nations; London: H.M. Stationery Office, 1955.) 10.50 dollars; 70*s*.

AS a reference work the value of this "Yearbook" appears to reside in the appendixes—which set forth the structure of the United Nations, the matters considered by the Principal Organs during 1954, the delegations to the General Assembly and the Councils, and the information centres and regional information centres—and in the documentary notes with which the several chapters are provided. These chapters themselves, however, although designed to facilitate the understanding of the work of the United Nations during the past year, appear to have rather a limited value except in official circles.

While the size and price of such an admirably printed and produced book restricts its general use, the chapters dealing with topics of interest to the scientist, such as the economic development of under-developed areas or the work of the United Nations Educational, Scientific and Cultural Organization or other specialized agencies, are not sufficiently detailed to preclude reference to the reports of various committees or other bodies. Something much more condensed might be of great value; even if there were discarded the material which gives a certain lack of realism to the treatment of questions regarding non-self-governing territories and the trusteeship system, some doubts may still be entertained as to the practicability of dealing readably in one volume with all the varied activities of the United Nations Organization.

Dictionary of Magic

By Harry E. Wedeck. (Midcentury Reference Library.) Pp. viii + 105. (New York: Philosophical Library, 1956.) 3 dollars.

THIS little book is a convenient compilation of names, terms and expressions used in magic and occultism generally, although it would have been improved had the author made a rather better selection of his material and arranged it somewhat differently. The subject is so vast that all that could be expected in a book of this size is a very brief and condensed list, which, for the general reader, is likely to prove of some use since it is unlikely that he would have by him the larger works by such authors as Collin de Plancy, Spence, Verneuil or even the shorter glossary by Ernest Bosc.

Although the author has managed to include some entries not easily found elsewhere, he has done so at the expense of omitting more important items, and it is sometimes difficult to see on what basis the selection has been made. Moreover, persons are listed under their first names; and such entries as "Last witch", "New", or "Plato", who is said to have censured sorcerers that were hired to practise incantations, seem of doubtful utility. A little more care would have avoided these faults and also minor errors such as the spelling of "Bavan" for "Bavent" and the confusion between the two Moras, which is more excusable since this confusion was made both by Summers and, following him, by Prof. E. M. Butler in her valuable study of ritual magic.

E. J. DINGWALL

Variational Principles in Dynamics and Quantum Theory

By Dr. Wolfgang Yourgrau and Stanley Madelstam. Pp. ix + 155. (London: Sir Isaac Pitman and Sons, Ltd., 1955.) 25*s*. net.

THE central importance of 'action' principles in modern theoretical physics fully justifies the authors in their attempt to provide a historical and critical exposition. Early chapters discuss the contributions of Fermat and Maupertuis; Dr. Akakia is not mentioned explicitly, but the authors appear to imply that König knew that the famous Leibniz letter was spurious—Is this quite certain? Then there is a technical section, dealing with the definitive work of Euler, Lagrange and Hamilton, and its applications to electrodynamics and quantum theory. Finally, a chapter on the philosophical aspects of action principles tries to maintain a balanced position, but inclines on the whole to the side of Planck rather than of Mach.

Thus two books have been cramped into a hundred and fifty pages, and on the whole it is the technical side which has suffered; for example, the extraordinary prescience of Hamilton's views is not adequately emphasized, and some technical ideas are brought in hurriedly and without due preparation, such as the relativistic interpretation of the modified Lagrangian function. Nevertheless, the mingling of historical and technical development is stimulating, and should assist the reader to a thorough realization of the immense value of the concept of action variation.

BRITISH ASSOCIATION MEETING IN SHEFFIELD

DURING August 29–September 5 this year, the British Association will hold its annual meeting in Sheffield. Sheffield has many advantages as a place of meeting for the British Association. One of the major centres of industry, exceedingly busy and dependent in almost every branch on the continuous application of scientific discovery, a visit provides a fine stimulus to any scientist; but, unlike most industrial centres, Sheffield is a surprisingly pleasant city, especially on its west and south sides, and it is set in surroundings of great natural beauty immediately accessible by bus or even on foot. Full advantage of these is being taken in the arrangements for the meeting. It is perhaps singularly appropriate that Sheffield should be chosen for the meeting this year, for a century ago, at the Cheltenham meeting in 1856, Bessemer made the first public announcement of his revolutionary steel-making process, for which shortly after he set up his own works in Sheffield.

The accommodation for the meeting will be divided between two centres. In the middle of the city, within easy reach of the railway stations and served by public transport from every district, will be the Reception Room (the Central Technical School—in the former Firth College). Within a few yards of this are the City Hall, where the large general meetings will be held, and the Cutlers' Hall, which will provide a convenient social centre. The section meetings will all be held in the University area, mostly in the University buildings. These are within easy walking distance of the Reception Centre; but, for the meeting, special buses for members will circulate between the Reception Centre and the section rooms, in addition to the regular public transport.

The inaugural meeting on the evening of Wednesday, August 29, will, as on a number of such occasions, be preceded by a short degree congregation, when the chancellor of the University, the Earl of Halifax, will confer honorary doctorates on Sir Raymond Priestley, president of the Association, and on Sir George Thomson and Sir Charles Goodeve, the presidents of Sections A and B, respectively. The president's address will be on "Twentieth Century Man against Antarctica", a subject most apposite and topical in view of the attention which is focused this year on the further exploration of the Antarctic by several important expeditions. Sir Raymond Priestley can speak with authority on this, because not only did he accompany both Shackleton and Scott to the Antarctic, but also he is still intimately associated with Antarctic exploration and development.

The two evening discourses will be on "The Growth of Biochemistry", by Prof. F. G. Young (August 31), and "The International Geophysical Year", by Prof. Sydney Chapman, chairman of the International Committee organizing the International Geophysical Year (September 3)—another subject of great topical interest.

It is, however, a prime object of the Association "to bring the objects of science more before the public eye". Many citizens who may be hesitant immediately to become members may yet wish to know more of what science means and to see at close quarters some of its leading figures. With them in mind, two further illustrated evening lectures have been arranged, freely open to the public, on "Antarctic Adventure", by Sir Raymond Priestley (August 30), and "The Future Development of Atomic Energy", by Sir John Cockcroft (September 4).

All these meetings will be held in the Main (Oval) Hall of the City Hall, which, seating 2,700, should accommodate the audiences in comfort.

But the heart of the gathering is in the meetings of the sections, and here will be encountered the richness and variety that have so long characterized the British Association. To summarize the very varied subjects that will be dealt with in presidential addresses and sectional communications would need a separate article. Here it may suffice to say that, while most aspects of scientific endeavour seem to be included, there will be, as is appropriate in a major centre of industry, a slight but appreciable emphasis on matters of industrial and technological importance, an emphasis reflected even in the proceedings of Section H, the general theme of which is to be "The Primitive Technology of Glass and Metals".

As in previous years, there will be an official service in Sheffield Cathedral on the Sunday morning, and other churches will hold special services. For the Sunday evening, the Local Committee has arranged for members a concert in the City Hall by the Hallé Orchestra and the Sheffield Philharmonic Choir, under Sir John Barbirolli and Mr. Herman Lindars.

A number of exhibitions have been arranged for the meeting, including one of polar rations, one of scientific glassware, and special displays at the City Museum and at the Graves Art Gallery, where there will also be a demonstration of the processes of picture restoration on an 'open evening'. It is hoped to arrange a display in honour of the Bessemer centenary, and, following the excellent lead given at Bristol, there will be an exhibition of "Science in Schools", organized by Mr. Stanley Moffett, director of education for Sheffield, and science masters and mistresses throughout the region. It is hoped to make this exhibition a fully 'live' show with most of the demonstrations and experiments actually working. A completely new departure will be a special exhibition of books *about* science arranged by the National Book League and staged in the Central Library. The professional scientist can generally find and assess the worth of technical books in his own field; but it is seldom that he can tell a lay friend where to find a book that explains the essentials in simple language—and outside his own field he is often quite lost. Here should be at least one answer to a difficult question, for which a great many members, scientists and laymen alike, may well be grateful. The regular showings of scientific films, begun in Bristol, will be continued in Sheffield in the convenient and well-equipped Library Theatre. Visitors to Sheffield will also be invited to inspect, in the same building, the Commercial and Technical Section of the Public Library, which provides a very important service for industry, commerce and the student.

The problem of housing the large number of members expected has been carefully studied. In particular, the whole accommodation of the University halls of residence and of the training colleges throughout the area has been reserved. Several of these are very recently built and are fine examples of collegiate architecture. Some are in former great houses, such as Wentworth Woodhouse, magnificently situated and of great historic interest as well as substantial comfort. Special bus services, free to residents, will run at appropriate times between the more distant of these and the meeting centres. Members wishing to stay in hotels should make early bookings. Arrangements have also been completed for ample private accommodation for those preferring it.

The main catering centre will be the lower floor of the City Hall; here a large restaurant with both cafeteria and waitress service will enable members to take lunch and other meals close to the Reception Centre and to the main bus station for excursions. Light refreshments will be available also in the University Union, there will be coffee points near all section rooms, and a mobile canteen on the Association's bus station will supply packed meals on demand.

Some 140 general and sectional excursions have been planned, and a member who so wishes will have little difficulty in getting, within the week, a general idea of the heavy and light industries of the area and in appreciating the glorious countryside in which they are set. A special bus station, within easy reach of the University and Reception Centre, will be brought into use solely for the Association, and nearly every excursion will start and end there.

Under the title of "Sheffield and its Region", an extensively illustrated scientific survey of some 330 pages by twenty-seven contributors under the editorship of Prof. D. L. Linton will be presented to members attending the meeting. In three parts, the first gives an account of what may be termed the natural history, pre-history and history of the region; the second treats of "The City of Sheffield" and deals with aspects of its economic development, with the growth of its social institutions, with its contributions to art and science, and with its present characteristics and plans for the future. The third part, under the heading "The Region Today", deals with some of the industries by which the inhabitants of the region gain their livelihood and with the towns, outside Sheffield, in which they live.

The community of Sheffield looks forward eagerly to receiving its distinguished visitors, who are assured of a cordial welcome. This will be the third time that the Association has met in Sheffield. The first was in 1879, with Henry Clifton Sorby as one of the local secretaries, when Crookes demonstrated many of the properties of cathode rays. That year was an important one in Sheffield, for a few weeks after the members of the Association had dispersed, Prince Leopold, youngest son of Queen Victoria, opened Mark Firth's foundation, Firth College, from which the University has grown. The second occasion was in 1910. The depression in the Sheffield industries during the inter-war years probably accounts for the long interval between the second and the present meetings. The Local Committee now hopes that, in a city and region so devoted to the applications of science, there may be a large enrolment of local members, and trusts that the occasion may prove memorable both in Sheffield and to all those who visit it.

LEWIS EVANS (1700–56): A SCIENTIST IN COLONIAL AMERICA

By Prof. GEORGE W. WHITE
Department of Geology, University of Illinois

LEWIS EVANS, who died two hundred years ago on June 11, earned his living as a professional engineer and cartographer; he was a geographer and natural scientist as well. He was born in 1700 at Llangwnadl, near Pwlheli, Carnarvonshire, Wales[1]. It is not known how and when he came to Colonial America; but in 1736 he was a surveyor and mapmaker in Philadelphia. He had associations with Benjamin Franklin, purchased books from him, and probably did some drafting and engraving for him. He travelled extensively with John Bartram, Botanist to the King; gave much information to Peter Kalm, the Swedish scientific traveller; and provided geographical and other service to Governor Thomas Pownall. These men and others of the time quote Evans's scientific opinions in their writings approvingly and at some length.

Evans made valuable observations on plants, animals, and meteorology, and in other fields of science. His knowledge of astronomy and physics ('natural philosophy'), including electricity, was such that he gave series of lectures on these subjects in 1751 in Philadelphia, Newark and New York. Thirteen lectures made up the series in New York. His maps of the middle-Atlantic Colonies went through more than twenty editions, although most of them were printed without credit to Evans. His topographical descriptions formed the physiographical groundwork for American geographical description (again usually without credit) for more than fifty years. His most important scientific contributions were his penetrating geological observations about eastern North America and the respectable theories, some of them far in advance of his time, that he based on them[2].

Evans travelled extensively through the middle Atlantic Colonies across the Coastal Plain, Piedmont, the folded Appalachian Mountains, and made at least one journey across the Appalachian Plateau to Lake Ontario. These observations were the basis of his maps of 1749 and 1752[3] of Pennsylvania and of his famous map of the Middle Atlantic Colonies of 1755[4]. In his journal[5] of a trip in 1743 to Lake Ontario (published by Governor Thomas Pownall in 1776), Evans noted the fossils in the Palæozoic rocks and understood their marine origin. He recognized that the present Appalachian ridges with their even skyline were erosional remnants and that the sediment derived from the erosion now forms the Coastal Plain. He says[6] the mountains " . . . were formerly but one large Plain, inclining with a considerable Slant towards the Sea; that this has been worn into its present Appearance of Ridges, with Vales between them, by the Rains of the Heavens and Waters of the Earth washing away the Soil from the upper Parts, and carrying it down to Seawards. That the Soil thus carried down and lodged in various Places hath in a Series of Ages formed the lower Plains of the Jerseys, Pennsylvania, Maryland, Virginia, and the Carolinas".

Near Lake Ontario Evans saw the raised beaches of the Pleistocene Great Lakes and correctly interpreted them as marking once higher water-levels. He further recorded at some length in his journal his opinion that the lakes had been partly drained, causing what is now called 'isostatic rebound'[7]: "This Part of America, disburthened of such a Load of Waters, would of course rise, as the immediate Effect of the shifting of the Center of Gravity in the Globe at once or by Degrees, much or little".

In his maps of 1749 and 1752 Evans recorded geological notes and filled in one extensive blank part with a lengthy description of the "Endless [Appalachian] Mountains". In his map of 1755 he could find no space for geological notes and published them separately in a booklet of 36 pages, "An Analysis of a General Map of the Middle British Colonies . . .", in which he gave a clear statement of the physiographical and geological provinces of what is now the eastern part of the United States, including New England. His classification (but not his terminology) of the separate physiographical provinces is that still in use. He expressed his regret that the map had no room for sections in several directions to show not only the hills and valleys on the upper surface, but also[8]: " . . . on the lower, the Nature of the Soil, Substrata and particular Fossils may be exprest. It was with Regret I was obliged to omit it. But in some future Maps of Separate Colonies, I hope to be furnished with more Room".

Evans had a keen realization of geopolitical realities—too insistently expressed for his own personal good and for his scientific future. He knew the richness of the country west of the mountains and the necessity of firmly attaching this heartland to the eastern provinces. This country he called the "Ohio country" and said is "The Flower of the whole Globe" and "the finest Country on Earth"[9]. He expressed most emphatically and pungently his opinion that the Colonial authorities were misguided, careless, stupid, and possibly even treasonable in allowing the French to penetrate from Canada into the territory west of the mountains and south of the Great Lakes—the territory now known as the "Middle West". Evans was sure any intelligent Briton could see that this land must be reserved for English settlement. This forthright, correct, but somewhat intemperate criticism of authority was poorly received; charges were preferred and he was jailed in New York in the spring of 1756. Evans, suffering from a "lingering indisposition", was released on June 8, on "his Majesty's Writt of Habeus Corpus", but died three days later on June 11.

It is tempting to speculate that had Evans lived a few more years, and devoted himself to cartography and science, maps of separate colonies would have been produced accompanied by geological sections and probably by further geological descriptions. He might have taken additional part in the developing studies of electricity and possibly in other phases of natural science. What he had already done ensures him a place in the history of science in Colonial America.

THE IVEAGH GEOLOGICAL LABORATORY, TRINITY COLLEGE, DUBLIN

By Prof. W. D. GILL

The reconstructed Iveagh Geological Laboratory at Trinity College, Dublin, was formally reopened on May 10 by the Chancellor of the University of Dublin, the Right Hon. the Earl of Iveagh, K.G., before a company of Fellows and staff of the College, and guests including many distinguished geologists from universities, the Civil Service and industry in Ireland and Britain. Before the reopening ceremony, the Chancellor had conferred the degree of Sc.D. (*honoris causa*) on Sir Harold Jeffreys (Cambridge), Prof. P. H. Kuenen (Gröningen) and Prof. H. H. Read (London).

The Chancellor recalled the deep impression made on him as a young man by Prof. John Joly. It was through his father's friendship with Joly, and his admiration for his work, that the association of the School of Geology and the Iveagh family had sprung. The abiding record of this friendship is an endowment of £10,000 to assist the work of this School.

The Iveagh Geological Laboratory is housed in the Museum Building, built under the influence of the principles of Ruskin between 1853 and 1857 to accommodate the Schools of Engineering and Geology. The building is certainly important and interesting, though perhaps controversial from the architectural and æsthetic points of view. The great columns of Irish marbles, including particularly fine samples of serpentine marble from Connemara, which support the arches of the Byzantine interior, are very impressive. Both engineering and geology were provided with very large museums, occupying the full 90 ft. of the width of the building at either end. These rooms covered 3,150 sq. ft. of floor space and were some 30 ft. high. The provision of teaching and research facilities was, however, on a greatly disproportionate scale, and could not be much improved. The main reconstruction has been the building of an upper floor in the old Geology Museum. A museum of type, figured, and reference collections now occupies 1,250 sq. ft. of the upper floor, the remainder being taken up by a mapping and photogrammetrical laboratory, a library and a research laboratory. Various oil companies and their associates have contributed generously towards the provision of photogrammetrical equipment, which is used both by geologists and geographers, and their generosity is recorded on a plaque on the wall of the photogrammetrical laboratory.

The floor of the former museum contains the main teaching laboratories and staff rooms. The three laboratories (elementary 956 sq. ft., palæontology 660 sq. ft., and petrology 550 sq. ft.) are dual-purpose rooms, permitting the fullest integration of lectures with practical demonstrations.

From the old accommodation at the level of the main hall of the building is retained a block of rooms, including the photographic room, preparation room and a laboratory for the research unit engaged under the direction of Mr. G. F. Mitchell, in Quaternary studies.

To offset the loss of display space in the new museum, the entrance hall has been furnished with wall cases, which display selections from the fine mineral and fossil collections, together with 'teaching gallery' exhibits intended to present various aspects of geology to the students of many departments who come to lectures in other parts of the building. On either side of the entrance hall stand skeletons of *Cervus giganteus*, perhaps the most famous of Irish fossil animals.

To the staff of the School of Geology has fallen the onerous task of removing, storing and replacing the museum collections. It was rewarding, however, to discover during this work the history of the School, and to see the stamp of those who made it. It is clear that the chair of geology was created in conjunction with the establishment of the School of Engineering in 1841; John Phillips was the first professor, followed after two years by Thomas Oldham. Although Oldham's main career lay in India, he forged a link between Irish and Indian geology which was to last until the end of the century. Ball, Meddlicott and Wynne are names common to the books of Trinity College and to the pioneering surveys of the Geological Survey of India. Meddlicott was prizeman in chemistry and geology in 1850. Oldham sent many specimens of minerals, rocks and fossils (including the Siwalik mammals) from India to enrich the collections. Oldham was followed by Samuel Haughton, whose interests and achievements ranged from the emplacement of granite to the fossil mammals of post-glacial times, and who finally became a distinguished medical scientist. Until 1881, the chair of mineralogy had a separate tenure. The first holder, James Apjohn, was also University professor of chemistry. The superlative quality of the mineral collections undoubtedly reflects the industry of collectors early in this field. To Prof. W. J. Sollas, who held the chair of geology for fourteen years before he went to Oxford, is owed the acquisition of the Huxley types of the Jarrow amphibia, and a great variety of type and figured specimens of his era. Most of the systematic collections of Irish rocks were started by him. John Joly's many-sided genius probably gave the School of Geology its highest and widest known reputation. Like many of its most distinguished sons, Joly came to the science of geology from the School of Engineering—and this, in the old days, meant through mineralogy. Joly remained throughout his life a keen collector of minerals, and his large collection, recently presented by Mrs. Henry Dixon, is particularly rich in metamorphic minerals.

The work of the late Prof. L. B. Smyth on the Carboniferous rocks and fossils of Ireland deserves wider recognition than it has received either in Trinity College or elsewhere. This unassuming man left a complete record of his meticulous comparative and descriptive work, which forms an invaluable foundation on which to build a study of the stratigraphy of the Carboniferous rocks covering two-thirds of the country. The fossils upon which the teaching of invertebrate palæontology is based also bear the stamp of a palæontologist of rare ability.

With this rich harvest from the labours of so many distinguished forbears, and the provision of up-to-date teaching and research facilities, the School of Geology in Trinity should be able to maintain the high reputation earned by its graduates over the past century. The main difficulty in expanding research activity is the poor provision in Ireland for postgraduate students compared with that in Britain. There is hope, however, that this situation will be remedied in the near future. In spite of these difficulties, the School of Geology has had two full-time research students in the past two years.

As many departments of geology in British universities have found in the past decade, there is much untouched research ground in Ireland, presenting a wide range of problems to be solved. The basic mapping of the country was done between 1860 and 1880, at a time when only the bare outlines of the science were established. It is not surprising, therefore, that field geology is so frequently rewarded by the discovery of undocumented phenomena. In the past, Ireland's own contribution to the rediscovery of Irish geology has had to rely on a few outstanding individuals. It is hoped that the new provision made by Trinity College will help to expand the scope, and increase the production of geological research.

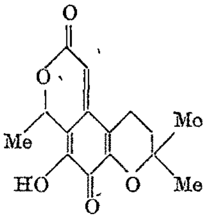
In field-mapping, petrographic and palæontological studies of Carboniferous rocks; in tectonics and the study of cleavage developed in fold systems; in field relationships and petrological studies of volcanics; in Quaternary studies, including the field-mapping and laboratory studies of drift deposits; in palæobotany and micropalæontology, there is ample scope for research workers, who will receive willing assistance from the University and from the Geological Survey of Ireland.

ANTIBIOTICS AND MOULD METABOLITES

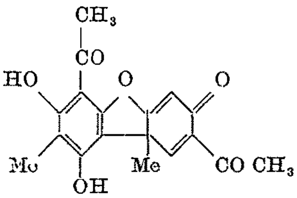
THE anniversary meeting of the Chemical Society was held this year in Nottingham, on March 26, and included a symposium on "Antibiotics and Mould Metabolites", organized by Prof. A. W. Johnson. Four papers were read during the morning: "Fungal Quinones", by J. H. Birkinshaw (London School of Hygiene and Tropical Medicine); "Synthesis of some Fungal Metabolites", by D. H. R. Barton (University of Glasgow); "Azaphilones, a General Survey", by A. D. G. Powell, Alexander Robertson and W. B. Whalley (University of Liverpool) and "The Structure of Purpurogenone", by J. C. Roberts (University of Nottingham).

Dr. Birkinshaw reviewed the chemistry of the fungal quinones and paid particular attention to the structural regularities which have enabled theories of biogenesis and metabolism to be developed. Examples of simple benzoquinones were quoted as well as dibenzoquinones, 2 : 5-diphenylbenzoquinones and the naphthaquinones, including actinorhodin which is possibly a dinaphthaquinone. The hydroxy-anthraquinones form the largest group of the fungal quinones, and these were sub-divided into those containing only α-hydroxy groups and those containing β- as well as α-hydroxy groups. The latter formed two main types, those based on emodin and those based on catenarin. Other hydroxy-anthraquinones which were not included in the above groups were also discussed. Examples of dianthraquinones and related compounds were cited, as well as the case of thelephoric acid, a phenanthraquinone. Citrinin, fuscin and purpurogenone form a separate class of hemiquinones or quinomethines, and the final examples mentioned included quinols and quinhydrones, the existence of which supports the idea that the quinones are concerned in the respiratory processes of the particular organisms. In the ensuing discussion, Prof. A. J. Birch (Manchester) stressed the importance of the acetate hypothesis in deciding the position of quinone substituents and in correlating the structures of the fungal quinones in general.

Prof. Barton then read his paper on the recent syntheses in his own laboratory of two fungal metabolites, fuscin and usnic acid. Fuscin was isolated by Michael in 1948, and its reactions and degradations were studied in detail by Birkinshaw, Bracken, Michael and Raistrick. Prof. Barton then deduced structure (I), which had been reported independently by Birch, for fuscin; he provided plausible explanations of its various reactions and described the total synthesis of the compound.

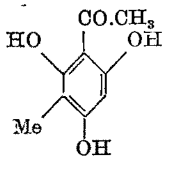


(I)

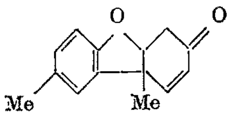


(II)

In a second section, Prof. Barton discussed the chemistry of usnic acid (II), which can be dissected into two biogenetic units of methylphloracetophenone (III). Once it had been realized that the dimer o p-cresol formed by ferricyanide oxidation should b formulated as (IV), a similar oxidation with methy phloracetophenone was found to give the expecte dimer which yielded racemic usnic acid on dehydration.



(III)



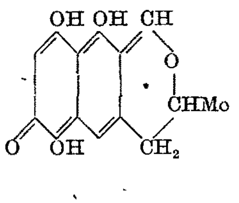
(IV)

In the discussion Prof. Barton said that the dime of *p*-cresol had also been obtained by oxidation wit peroxidase by earlier workers; but even so it had no been obtained in an optically active form, probabl because the reaction had not been carried out unde proper physiological conditions.

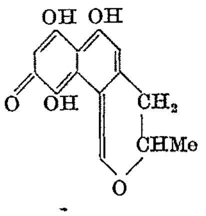
In the third paper, by Powell, Robertson an Whalley, Dr. Whalley gave a general survey of th complex chemistry of the azaphilones, a group o five pigments: sclerotiorine, $C_{21}H_{23}O_5Cl$, from *P. sclerotiorium* van Beyma; a new pigment, rotiorine $C_{22}H_{22}O_5$ (or $C_{23}H_{24}O_5$), from the same organism monascin, $C_{21}H_{26}O_5$, and monascorubrin, $C_{22}H_{24}O_5$ both isolated from *M. purpureus* Wentii; and a new metabolite, rubropunctatin, $C_{22}H_{24}O_5$, from *M. rubriginosus* Sato. These metabolites constitute a famil of substances of hitherto unknown type, which, wit the exception of monascin, give rise with exceptiona facility to reaction products with ammonia. Henc these metabolites, which have many structura features in common (*inter alia*, the presence of lactone grouping and one or more alkyl side-chains the absence of hydroxyl groups and aromatic nuclei and the ready conversion of the 'ammonia compounds' to *iso*quinolines), are designated by th generic term azaphilones.

The extensive analytical work concerning th structure of sclerotiorine has made it possible t assign a tentative structure to this pigment.

In the final paper of the morning session, Dr Roberts discussed the isolation and structure (V) o the mould pigment purpurogenone, $C_{14}H_{12}O_5$, isolate from *P. purpurogenum* Stoll. Details were given of th various reactions of purpurogenone, including the conversion by alkali to a derivative of naphthapurpuri and the chromic acid oxidation of purpurogenon triacetate to 3-hydroxybenzene-1 : 2 : 5-tricarboxyli acid.



(V)

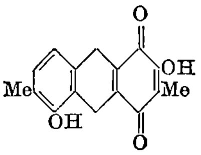


(VI)

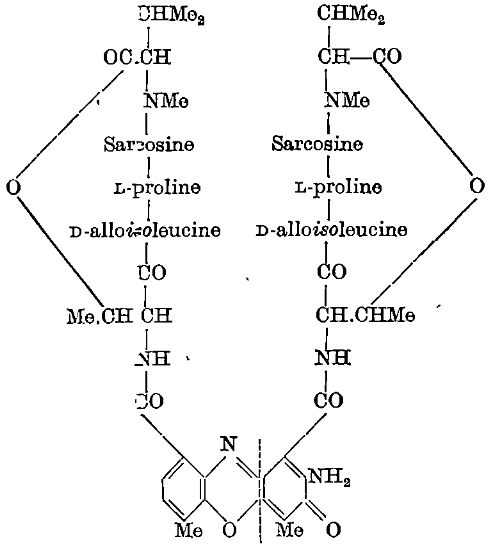
A possible biogenetic route based on the acetate hypothesis was supported. A lively discussion of various features of this novel structure occurred, and suggestions were made for distinguishing (V) from the alternative, though less likely, angular structure (VI).

In the afternoon three papers were read: "Progress in the Chemistry of Oxytetracycline and Related Compounds" by L. H. Conover (Chas. Pfizer and Co., Inc., New York); "Actinomycin", by A. W. Johnson (University of Nottingham) and "Chemistry of the Cephalosporins", by E. P. Abraham and G. G. F. Newton (University of Oxford), read by the latter.

Dr. Conover began his talk by reminding his audience of the structural relationship between terramycin (VII) and aureomycin, both derivatives of tetracycline and now officially named oxytetracycline and chlorotetracycline respectively. He then summarized briefly the degradative experiments which enabled these structures to be deduced. The main part of Dr. Conover's talk was devoted to recent work on oxytetracycline and comprised (i) the interpretation of certain aspects of the spectra and the acidities of simpler structures related to the antibiotics; (ii) the use of model compounds in elucidating the primary site of metal complexing of the antibiotics; (iii) the identification of the specific centres responsible for the three titratable acidic dissociations of the antibiotics; and (iv) some new reactions of oxytetracycline and its analogues. In the first section, evidence was presented for steric inhibition of resonance being an important factor as well as variations in the strength of hydrogen bonding in controlling the physical properties of *o*-hydroxy- and *o*-alkoxyaromatic carbonyl compounds. In the second and third sections, it was established that the site of the metal complexing is the 2-acyl-8-hydroxytetralone fragment of the molecule, and that the three acidic groups of pK_a 3·3, 7·3 and 9·1 in oxytetracycline can be attributed to the tricarbonylmethane system (VII; *A*), the ammonium cation (VII; *B*) and the phenolic β-diketone system (VII; *C*), respectively.

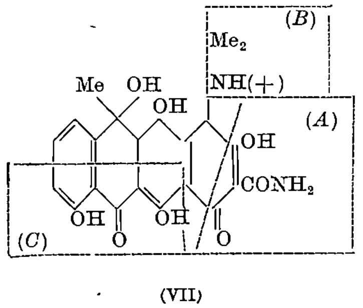


(VIII)



Actinomycin C_3 $C_{64}H_{90}O_{16}N_{12}$ (Brockmann)

(IX)

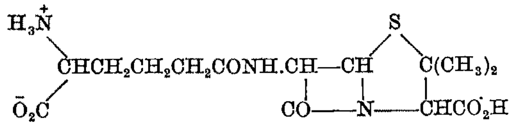


(VII)

In his final section Dr. Conover put forward theoretical mechanisms for the unexpected formation of tetramethylammonium iodide from the action of methyl iodide on oxytetracycline and postulated that the observed epimerization of the tetracycline antibiotics in acidic solution involves equilibration at C_4.

Prof. Johnson outlined the isolation, nomenclature and early work on the structure of the actinomycin group of antibiotics which have been claimed to have a certain degree of cytostatic activity. The difference between the various members of the groups lies in the composition of the peptide chain and, so far as is known, the chromophore is common to all. Until recently the only degradation product from actinomycin was the compound despeptidoactinomycin or actinomycinol, produced by the action of baryta. The structure of this compound (VIII) was announced in papers submitted from both Göttingen (Brockmann *et al.*) and Cambridge on the same day. Quite recently, Brockmann has been able to advance a complete structure (IX) for actinomycin by a careful study of the graded acid hydrolysis. This structure is remarkable because of its relation to xanthommatin, an insect pigment recently isolated and identified by Butenandt, and also because it can be synthesized *in vitro* as well as *in vivo* by the oxidative coupling of two molecules of the 6-hydroxy-5-methylanthranilic acid peptide. Variations in the peptide chain and unsymmetrical coupling can give rise to the various actinomycins.

In the final paper, Dr. Newton said that a *Cephalosporium* sp. (obtained from Prof. Brotzu) produces two groups of antibiotics. One group, cephalosporin P, contains five related antibiotics that can be extracted into solvents. The other group contains two hydrophilic substances—cephalosporin N and cephalosporin C. Cephalosporin P_1 ($C_{32}H_{48}O_8$), the major component of the cephalosporin P family, contains an αβ-unsaturated carboxyl, two hydroxyl and two acetoxy groups. The $C_{27}H_{39}$ residue is tetracyclic. Cephalosporin P_1 is related to helvolic acid ($C_{32}H_{42}O_8$). Cephalosporin N is a new type of penicillin having a residue of D-α-aminoadipic acid in the side-chain. Its physical and antibacterial properties differ strikingly from the penicillins previously encountered. Degradation studies have shown that cephalosporin N is very probably (*D*-4-amino-4-carboxy-*n*-butyl)penicillin (X).



(X)

Cephalosporin C ($C_{16}H_{21}O_8N_3S$) behaves like a penicillin in some respects but not in others. Like cephalosporin N, it contains a residue of D-α-aminoadipic acid in the side-chain and has an absorption band in its infra-red spectrum characteristic of a penicillin. Unlike cephalosporin N, it shows an absorption band ($\varepsilon_{\max.}$ 9,000) at 260 mμ, is not inactivated by penicillinase and gives no penicillamine on hydrolysis with hot acid. However, DL-valine has been isolated from the hydrolysate of cephalosporin C treated with Raney nickel.

The papers of the symposium, with bibliographies, will be published by the Chemical Society as "Special Publication No. 5", which will include also an account of the discussions following each paper.

A. W. Johnson

OBITUARIES

Dr. Stanley Whitehead

By the death of Stanley Whitehead on May 5 at the early age of fifty-three, electrical engineering has lost one of its far-sighted leaders in the research field and the Electrical Research Association a director who has considerably widened its scope and activities. He entered Oxford with an open scholarship, where he took firsts in the Final School in Physics and Mathematical Moderations. In 1925 Whitehead accepted the post of physicist in the Electrical Research Association and proceeded to a part-time study of electrical engineering at East London (Queen Mary) College, which led in 1930 to a Ph.D. and in 1952 to a D.Sc. degree of the University of London.

His early work with the Electrical Research Association led to the production of three critical surveys of dielectric phenomena covering breakdown phenomena in solid, liquid and gaseous dielectrics. This interest in dielectrics was maintained throughout his career and culminated in the monograph "Dielectric Breakdown of Solids" (Clarendon Press, Oxford, 1951), in which dielectric failure in all its aspects, for example, electronic breakdown, breakdown through thermal effects and by discharges in gaseous voids, was surveyed. His own theoretical researches on thermal breakdown and his experimental researches with colleagues on void discharges have proved useful contributions to knowledge. Problems of electrotechnical interest to which he has made contributions include those concerned with electrical transmission, cable ratings, and telephone and radio interference. During the Second World War he took a leading part, often at considerable personal risk, in the work of the Electrical Research Association on mine and bomb location.

Whitehead shouldered many responsibilities. He was chairman of the Science Abstracts Committee of the Institution of Electrical Engineers and a past chairman of the Measurements Section, honorary treasurer of the Institute of Physics, and a past vice-president and chairman of the London Branch, a past joint-secretary of the Parliamentary and Scientific Committee, and the chairman of the Committee of Directors of Research Associations. He was the chairman of the governors of his old school, Sir Walter St. Johns, of Battersea, and a governor of Battersea Grammar School. But his interest in education did not stop there; many young graduates about to embark on a career in research received guidance, and often he was instrumental in securing for them financial support. One of the rewards accorded him in 1952 which gave him great pleasure was his fellowship of Queen Mary College.

Stanley Whitehead married in 1929 Mary Lyon Morehead; they had met at Oxford, where she too had a distinguished academic career, but on the classical side. There are two children of the marriage, a boy and a girl.

R. Davis

Dr. T. Richards

Taliesin Richards, senior lecturer in the Department of Microbiology, University of Reading, died on January 13 at the early age of forty-two, having been born on November 26, 1913; his loss to the Department is great. Richards read chemistry at King's College, University of London, and obtained a B.Sc. with first-class honours in July 1936. He then entered the London School of Hygiene and Tropical Medicine to read for the postgraduate diploma in bacteriology, which he obtained in July 1937. Thus he entered the field of microbiology by postgraduate study, building upon a foundation of general chemistry a knowledge of microbial physiology and microbial forms and the techniques for studying them. He continued at the London School of Hygiene, doing research in the department of Prof. H. Raistrick, for which he obtained a Ph.D. in 1939.

In September 1939 Richards was appointed independent lecturer in charge of the, then, Agricultural Bacteriology Laboratory in the Faculty of Agriculture, University of Reading, where students reading for the degree of B.Sc. in dairying received instruction in microbiology. Richards and his colleagues were also responsible for the course for the postgraduate diploma in general bacteriology (now discontinued). These courses owed much to Richards, who moulded them during the difficult war period and after. The experience gained in the design and teaching of these courses was of much value when later (March 1951) the laboratory was absorbed into a new Department of Microbiology in the Faculties of Science and of Agriculture. Richards was appointed senior lecturer in the new Department and continued to be particularly concerned with the courses for the B.Sc. (Dairying) degree. In planning the courses for the new degree subject of microbiology in the Faculty of Science, Richards's knowledge and experience were drawn upon to great advantage, and he himself did a considerable amount of teaching in these new courses. Richards was a good teacher and took much atient interest in the problems of students both in nd out of the laboratory. He was much interested n student life in the University generally, and delighted in following the careers of his former tudents.

Richards's scientific interests covered a wide field in bacteriology. His papers included studies on the eat disinfection of *Streptococcus faecalis*, the development of media for the detection and enumeration of ipolytic micro-organisms, and the development of hemically defined media for classification in the *oli-aerogenes* group. He was an excellent microcopist and photographer. In spite of the difficult ituation in the laboratories during the War and the ater changes consequent on re-organization and development, Richards always managed to keep some personal research interests going, and to supervise a succession of research students.

Richards was an active member of the Society for Applied Bacteriology; he was elected to the committee in 1943, became an assistant editor of the *Proceedings* of the Society in 1945 and was its editor during 1948–50, until compelled by ill-health to resign. By then he had been able to carry out much work preparatory to the appearance of the *Journal of Applied Bacteriology*, and he continued until his death to give valuable assistance to his editorial successors. Richards was an active member of the Association of University Teachers and was for two years a Central Council representative of the University of Reading branch. He leaves a widow and two sons.

B. C. J. G. Knight

NEWS and VIEWS

The Queen's Birthday Honours

The following names of scientists and others associated with scientific work appear in the Queen's Birthday Honours list:

Viscount: Lord Cherwell, lately Dr. Lee's professor of experimental philosophy in the University of Oxford, for public services.

Barons: Sir Henry Cohen, professor of medicine n the University of Liverpool, for services to medicine; Sir Ronald Weeks, chairman of the National Advisory Council for Education in Industry and Commerce, and president of the British Scientific Instrument Research Association.

O.M.: Lord Hailey.

K.C.B.: Sir Gordon Radley, director-general of the General Post Office.

K.B.E.: Lord Glentanar, member of the Scottish Agricultural Advisory Council; Edmund G. Harwood, deputy secretary, Ministry of Agriculture, Fisheries and Food; Hugh N. Hume, deputy chairman, Colonial Development Corporation, and for other public services; Sir Thomas Merton, treasurer of the Royal Society.

Knights: Prof. Samuel P. Bedson, emeritus professor of bacteriology, University of London; Prof. Harry G. Champion, professor of forestry, University of Oxford; Prof. William J. Pugh, director of the Geological Survey of Great Britain and the Museum of Practical Geology (Department of Scientific and Industrial Research); Allan S. Quartermaine, president during 1951–52 of the Institution of Civil Engineers; John F. Wolfenden, vice-chancellor of the University of Reading.

C.B.: J. Anderson, chief scientist, Admiralty Signal and Radar Establishment, Portsdown, Cosham, Hants; H. S. Gilham, assistant comptroller, Patent Office (Board of Trade); J. I. Magowan, lately permanent secretary, Ministry of Agriculture, Northern Ireland.

C.M.G.: D. H. Black, chief scientific officer, Ministry of Supply; Dr. C. E. Lucas, director of marine and freshwater fishery research, Scottish Home Department.

C.B.E.: C. B. Bisset, director of the Geological Survey, Tanganyika; L. Boddington, deputy chief scientific officer, Ministry of Supply; Dr. F. P. Bowden, reader in physical chemistry, University of Cambridge; R. M. Currie, head of the Work Study Department, Imperial Chemical Industries, Ltd.; J. R. V. Dolphin, chief engineer, Atomic Weapons Research Establishment, United Kingdom Atomic Energy Authority; A. S. Fortune, chief inspector, Department of Agriculture for Scotland; E. T. Green, for services to agriculture in Northern Ireland; Dr. P. D'Arcy Hart, director of the Tuberculosis Research Unit, Medical Research Council; G. V. B. Herford, deputy chief scientific officer, Pest Infestation Laboratory (Department of Scientific and Industrial Research); A. B. Mann, chief mechanical and electrical engineer, Ministry of Works; Prof. K. Mather, professor of genetics, University of Birmingham; J. E. Peat, deputy senior officer, Empire Cotton Growing Corporation, Tanganyika; J. D. Peattie, chief engineer, Central Electricity Authority; S. P. Peters, deputy director (forecasting), Meteorological Office (Air Ministry); G. Williamson, principal of the Veterinary School, Federation of Nigeria; F. N. Woodward, director of the Institute of Seaweed Research.

I.S.O.: J. F. Sinclair, principal, Ministry of Agriculture, Fisheries and Food; R. I. Wells, principal scientific officer, Air Ministry.

Directorship of the Science Museum, London: Dr. T. C. S. Morrison-Scott

Dr. T. C. S. Morrison-Scott, a principal scientific officer in the British Museum (Natural History), has been appointed director of the Science Museum, London, in succession to the late Dr. F. Sherwood Taylor. Dr. Morrison-Scott was born in 1908; he went to Christchurch, Oxford, where he read history and law, and later to the Imperial College of Science and Technology, where he graduated with first-class honours in zoology in 1935. After a period as a biology master at Eton, he became a research student at the Zoological Society of London, and joined the British Museum (Natural History) in 1936. During the Second World War, he served with the R.N.V.R., and was awarded the Distinguished Service Cross. During the earlier part of his career Dr. Morrison-Scott was mainly interested in ecology in relation to evolution. At the British Museum he was assigned to the Mammal Section of the Zoological Department, under M. A. C. Hinton, and ultimately he assumed charge of that section. After the War he also became the officer in charge of the Tring Museum. His research work has covered a wide range of mammalian topics from historical investigations into such matters as the identity of the kangaroo discovered by Captain Cook's expedition in 1770 and of the cats of ancient Egypt, to morphological investigations into the growth and succession of elephants' teeth. His major contributions have, however, been in the field of taxonomy; publications such as the Check List of Palæarctic Mammals (jointly with J. R. Ellerman, 1951) and Southern African Mammals (with J. R. Ellerman and R. W. Hayman, 1953) won immediate recognition and have become standard works of reference. In addition to his work in the Museum he has played a prominent part in other zoological affairs. He has been honorary treasurer since 1950 of the Zoological Society of London. At the thirteenth and fourteenth International Congresses of Zoology he was much involved in the activities of the Section on Zoological Nomenclature, and he is the honorary treasurer of the forthcoming fifteenth Congress in London in 1958. Among his hobbies are sailing and skiing; he is an amateur astronomer and is no mean lathe-turner.

Prehistoric European Archæology in London : Prof. J. D. Evans

Mr. J. D. Evans, whose appointment to the chair of prehistoric European archæology tenable at the University of London Institute of Archæology has recently been announced, is an outstanding product of the Department of Archæology and Anthropology at Cambridge. After taking his Tripos, in which he gained a first class with distinction, Mr. Evans entered on a course of research on the prehistoric archæology of the Mediterranean with special reference to relations between the eastern and western basins. He began by studying the Neolithic and Early Metal Age cultures of Spain, working under Santa-Ollala at Madrid and under Pericot y Garcia at Barcelona. Next he held a fellowship at the British Institute of Archæology at Ankara, during the tenure of which he took part in excavations, not only in Turkey, but as far afield as Jericho. At this stage his original plan was interrupted by an invitation from the Royal University of Malta to prepare a survey of the known monuments and archæological material from the Maltese Islands. In his paper on "The Prehistoric Culture-Sequence in the Maltese Archipelago", published in the *Proceedings of the Prehistoric Society* (19, 41; 1954), Evans made known the results of his analysis of the pottery, and he has since, in a communication to the Society of Antiquaries, of which he was elected a Fellow in 1955, published the results of his own excavations, by means of which he has been able to confirm his sequence and to relate to it the main prehistoric structures of the islands. Mr. Evans, who has held a research fellowship at Pembroke College, Cambridge, since 1953, has thus gained that broad experience of European prehistory that one has a right to expect of the successor to Prof. V. Gordon Childe.

Physics at Exeter: Dr. G. K. T. Conn
